Preface

Bless upon God Almighty such that this proceeding on 3rd International Conference on Research, Implementation, and Education of Mathematics and Sciences (ICRIEMS) may be compiled according to the schedule provided by the organizing committee. All of the articles in this proceeding are obtained by selection process by the reviewer team and have already been presented in the Conference on 16 – 17 May 2016 in the Faculty of Mathematics and Natural Sciences, Yogyakarta State University. This proceeding comprises 9 fields, that is mathematics, mathematics education, physics, physics education, chemistry, chemistry education, biology, biology education, and science education.

The theme of this 3rd ICRIEMS is '*The Global Challenges on The Development and The Education of Mathematics and Science*'. The main articles in this conference are given by six keynote speakers, which are Prof. Allen Price, Ph.D (Emmanuel College Boston USA), Ana R. Otero, Ph.D (Emmanuel College Boston USA), Dr. Michiel Doorman (Utrecht University, Netherlands), Prof. Dr. Marsigit, M.A (Yogyakarta State University), Asst. Prof. Dr. Warakorn Limbut (Prince of Songkla University, Thailand), and Prof. Dr. Rosly Jaafar (Universiti Pendidikan Sutan Idris, Malaysia). Besides the keynote and invited speakers, there are also parallel articles that presented the latest research results in the field of mathematics and sciences, and the education. These parallel session speakers come from researchers from Indonesia and abroad.

Hopefully, this proceeding may contribute in disseminating research results and studies in the field of Mathematics and Sciences and the Education such that they are accessible by many people and useful for the Nation Building.

Yogyakarta, May 2016

The Editor Team

Forewords From The Head Of Committee

Assalamu'alaikum warahmatullahi wabarakatuh

May peace and God's blessings be upon us all

First of all, allow me to thanks to God, Allah SWT, who has been giving us blessing and mercies so we can join this conference. Ladies and Gentlemen, it is my great honor to welcome you to Indonesia, a unique country which has more than 17,000 islands, more than 1,300 ethnic groups, and more than 700 local languages, and I am also very happy to welcome you to Yogyakarta, the city of education, culture, tourism, and a miniature of Indonesia. We wish you be happy and comfortable in attending the conference in this city.

The third International Conference on Research, Implementation, and Education of Mathematics and Science (ICRIEMS 3rd) 2016 is organized by the Faculty of Mathematics and Science, State University of Yogyakarta. In this year, theme of the conference is : The Global Challenges on The Development and The Education of Mathematics and Science. This conference are dedicated to the 52nd anniversary of Yogyakarta State University and to face challenges of Asean Economic Community in 2016.

This conference facilitates academics, researchers and educators to publish and disseminate their research in the fields of pure, application and education of Science and Mathematics. Furthermore, the purposes of the conference are to establish interaction, communication, and cooperation among academics, researchers and educators at an international level.

On behalf of the committee of this conference, I would like to express our highest appreciation and gratitude to the keynote speakers, including:

1. Allen Price, Ph.D. (Associate Professor of Emmanuel College, Boston USA)
2. Ana R. Otero, Ph.D. (Emmanuel College, Boston USA)
3. Dr. L.M. (Michiel) Doorman (Associate Professor of Utrecht University, Netherland)
4. Prof. Dr. Marsigit, MA. (FMIPA, Universitas Negeri Yogyakarta)
5. Asst. Prof. Dr. Warakorn Limbut (Faculty of Science, Prince of Songkla University, Thailand)
6. Prof. Dr. Rosly Jaafar (Faculty of Physics, Universiti Pendidikan Sultan Idris, Malaysia)

Furthermore, we inform you that the papers presented in this conference are about 200 papers from 302 applicants, who come from various countries and various provinces throughout Indonesia. Therefore, I would like to give my appreciation and many thanks to the presenters and participants who have been actively involved in this seminar.

Finally, I would like to thank the committee members who have been working very hard since half a year ago to ensure the success of the conference. However, if you find any shortcomings and inconveniences in this conference, please forgive us. We would very happy to receive your suggestions for improvement in the next conference. Thank you very much.

Wassalamu'alaikum warohmatullahi wabarakatuh.

Yogyakarta, May 2016

Dr. Warsono, M.Si.

Forewords From The Dean Of Faculty Of Mathematics And Sciences, Yogyakarta State University

Assalamu'alaikum warahmatullahi wabarakatuh. My greetings for all of you. May peace and God's blessings be upon us all.

On behalf of the Organizing Committee, first of all allow me to extend my warmest greeting and welcome to the International Conference on Research, Implementation, and Education of Mathematics and Sciences, the third to be held by the Faculty of Mathematics and Science, State University of Yogyakarta, one of the excellent and qualified education universities in Indonesia. This conference is also celebrate the 52th Anniversary of State University of Yogyakarta.

This conference proudly presents keynote speeches by six excellent academics, these are: Allen Price, Ph.D., Ana R. Otero, Ph.D., Dr. Michiel Doorman, Prof. Dr. Marsigit, MA., Asst. Prof. Dr. Warakorn Limbut, and Prof. Dr. Rosly Jaafar, and around 200 regular speakers.

The advancement of a nation will be achieved if education becomes a priority and firmly supported by the development of technology. Furthermore, the development of technology could be obtained if it is supported by the improvement of basic knowledge such as mathematics, physics, chemistry, and biology. The empowerment of this fundamental knowledge may be achieved by conducting research which is then implemented in developing the technology and the learning process in schools and universities.

This international conference is aimed to gather researchers, educators, policy makers, and practitioners to share their critical thinking and research outcomes. Moreover, through this conference it is expected that we keep updated with new knowledge upon recent innovative issues and findings on the development and the education of mathematics and science, which is in accord with the theme of the conference this year. All material of the conference which are compiled in the abstract book and proceedings can be useful for our reference in the near future.

This conference will be far from success and could not be accomplished without the support from various parties. So let me extend my deepest gratitude and highest appreciation to all committee members who have done an excellent job in organizing this conference. I would also like to thank each of the participants for attending our conference and bringing with you your expertise to our gathering. Should you find any inconveniences and shortcomings, please accept our sincere apologies.

To conclude, let me wish you fruitful discussion and a very pleasant stay in Yogyakarta.

Wa'alaikumsalam warahmatullahi wabarakatuh

Lesson Study Among the Move of Educational Reformation in Indonesia

Marsigit
Department of Mathematics Education, Faculty of Mathematics and Science,
Yogyakarta State University

Abstract-Since the year of 2000, Government of Indonesia (GOI) and JICA-Japan has been experienced initiating, developing and implementing lesson studies activities to improve teaching learning quality in primary schools, secondary schools, and in universities; it covers the teaching learning of mathematics, natural sciences, social sciences, and languages. The Lesson Study activities was proven to be effective in lifting students' enthusiasm in learning science, helping students to develop their experimental and discussion skill, and in giving opportunities to students in developing their own scientific concept by themselves. It was also noted that by using constructivism approach, the students may find out their best style of learning. Competition rises among groups of students in presenting the results of their work and in defending their presentations. This forces students to learn more theory more for their own sake. As a result of Lesson Study activities there were many teaching material developed either by lecturers or by teachers. Through lesson study activities lecturers and/or teachers developed the teaching materials after thinking extensively what and how to develop teaching materials for a certain topic, and then develop the materials. In sum, at the schools and implementation level, lesson study was the succes story of teachers' professional development in Indonesia. However, it seems it has its struggle to employ those success come into the higher level of teachers; professional development i.e. the government policies of educational development. Whilest, the ministry of education strives to implement the new curriculum for primary and secondary schools and also for universities, the lesson studies activities looks like the beautiful girls who loose its accountability and its narations. The challenge is to what extent that the lesson study is to be able to contribute its role to support government effort to improve the quality of teaching at all levels.

Keywords: lesson study, quality of teaching, teachers' professional development

I. INTRODUCTION

Nowadays, lesson study has become a worldwide movement to improve teacher's professional development. It rooted from the the old Japanesse educational practice i.e. in the Meiji period of Japan, in which the teachers were willing to develop and reflect their own teaching in collaboration with other teachers. Since the 1960s, lesson study has been developed rapidly in Japan as a school-based in-service training of the candidates of teachers. Following the world conferences and seminars of lesson studies e.g. supported by JICA, APEC, Walls, CRICED, and CRME, lesson study then spread out around the world. Some countries has developed lesson studies as the bases for improving the quality of teaching and teachers' professional development. United Kingdom, China, USA, Australia, Thailand Singapore, Russia, Eastern Europe contries, some Africa's, South East Asian countries including Indonesia has experiences conducting lesson studies with their educational contexts.

International Cooperation on Lesson Study was started with the meeting of the third APEC Education Ministerial held on 29-30 April 2004 in Santiago. The meeting suggested to conduct a collaborative study on innovations for teaching and learning mathematics in different cultures among the APEC Member Economies. The recommended project then was managed by the Center for Research in Mathematics Education (CRME) of Thailand and the Center for Research on International Cooperation in Educational Development (CRICED) of Japan. Some theme were chosen: Mathematical Thinking, Communication, Evaluation and Generalization. The purpose of project were to collaboratively share the ideas and ways of mathematical thinking which is necessary for science, technology, economical life and development on the APEC member economies, and collaboratively develop the teaching approaches on mathematical thinking through Lesson Study among the APEC member economies. In the document of "APEC – Tsukuba International Conference on Innovative Teaching Mathematics through Lesson Study

(II)- Focusing on Mathematical Thinking –“ it was organized to support specialist Lesson Study from Chile, China, Indonesia, Malaysia, Mexico, Papua New Guinea, Peru, Philippines, Russia, Thailand, and Vietnam.

All sides aggre that one of the role of lesson study activities is to shift the old paradigm to the new ones.

Table 1: The Paradigmatic Changes Promoted by lesson study

Old Paradigm	**Recommended Pradigm**
Education as investment	Education as a need
Learning as an obligation	Learning as a need
Short-term orientation	Long-term orientation
Competiton	Cooperation
Instrumental curriculum	Interactive curriulum
Teachers as curriculum implementers	Teachers as curriculum developers
Dominant teachers/teacher-centred	Students’ initiations/student centred
Very structured curriculum	Flexible curriculum
Product oriented	Process and product oriented
Uniformity	Diversity
Single method (lecturing)	Various methods (lecturing, discussion, ecperiment, investigation, practical work)
Transfer of knowledge	Constructivist
Stressing on theories	Theories and practice
Cognition	Affective, cognition and skills
Text-book oriented	Life oriented
Objective test	Authentic assessment/portfolio
Exit national exam as an end	Exit national exam as a tool for improving the qualotu of education

Mixing from values beliefs and empirical evidences, there are currently demands in Indonesia, that any educational reform should handle the issues of: (a) how to promote interactive curriculum rather than instrumental curriculum?, (b) how to promote student centered approach rather than teacher centered approach?, (c) how to promote students’ initiation rather than teacher’s domination?, and (d) how to promote simple and flexible curriculum rather than crowded and tight-structured curriculum? While in term of observable good practice, there were demands that teachers need to have a chance to reflect their teaching in such away that they may move from older paradigm of teaching to the new one. Teachers may move from emphasizing the “teaching” to emphasizing the “learning”; they may move from the act of “transferring teacher’s knowledge” to “constructing students’ knowledge”.

The Decree of Sisdiknas No. 20 year 2003, Indonesian Educational System should develop intelligence and skills of individuals, promoting good conduct, patriotism, and social responsibility, fostering positive attitudes of self reliance and development. Improving the quality of teaching is one of the most important tasks in raising the standard of education in Indonesia. The programs which have been carried out to improve the quality of teaching are the improvement the quality of teachers; the provision of learning facilities and equipment; the improvement of the curricula for basic education; and, the development and utilization of communication technology for education, in support of the teaching learning process. The improvement of the quality of teaching, thus, has been one of the fundamental issues in the improvement of the quality of education in Indonesia. The quality of teaching learning process is closely related with what the students do in the classroom.

The School-Based Primary mathematics curriculum outlines that the aims of teaching learning of mathematics are as follows: to understand the concepts of mathematics, to explain the relationships among them and to apply them to solve the problems accurately and efficiently; to develop thinking skills to learn patterns and characteristics of mathematics, to manipulate them in order to generalize, to proof and to explain ideas and mathematics propositions; to develop problems solving skills which covers understanding the problems, outlining mathmatical models, solving them and estimating the outcomes; to communicate mathematics ideas using symbols, tables, diagrams and other media; to develop appreciations of the uses of mathematics in daily lifes, curiosity, consideration, and willingness to learn mathematics as well as tough and self-confidence.

Since the 2014s, the Ministry of Education has implemented the new centralized curriculum, called Curriculum 2013. From its start, it seems that the implementation of the new curriculum faces the huge gap between the ideals and the practicality. By introducing the new curriculum, government wish to inprove the quality of education. The curriculum consists of many concept of changes and revisison of the previous curriculum. Scientific method was introduced as the only single approach for teaching at all level and for all subjects. Through the new curriculum, the government let the teachers to employ the methods which is conform with the scientific approach, e.g problem-based method, project-based method, discovery method, and cooperative method. For the younger learner i.e primary schools, the government was also intruduced integratif and thematic approach.

However, there are significans finding that the implementation of Curriculum 2013 has many fundamental problems related to teachers'competencies and class, school management and leaving examination system. The teachers has its culture with conventional teaching, and it is not easy to change the teachers' mindset of teaching. The problems also emerge from how to manage teachers' competencies and teachers backgrounds in order to match with the structure of curriculum; some big changes heppened from this matter due they are also related with the teachers'certification. Some teachers perceive and argue about the relevant and significant of the final examination; they think that national examination system does not really concord with the methods of teaching and students activities to be promoted.

From the stated curriculum, it can be learned that teaching learning mathematics involves the teaching of many different areas of knowledge, and of many skills. When new knowledge or skills are required for problem solving, the students need to develop their mathematical attitude. Katagiri, S. (2004) suggests that, to develop mathematical attitude, students need to realize which previously learned, to "sense the necessity of" and "perceive the need or desirability of using" new knowledge and skills. It concludes that it is important to conduct classroom-based research to investigate the necessary driving factors towards the required knowledge and skills. It is also important to make sure that students first understand the benefits of using knowledge and skills when they possess and utilize such a drive. This leads them to fully acquire the knowledge and skills they have used. Cultivating the power of students to think independently and to perform mathematical attitude and mathematical thinking will be the most important finding in this research.

In Indonesia the Lesson Studies were developed in which the teachers, in collaboration with Lecturers and Japanese Experts, tried out some teaching models at schools. The Lecturers of Teacher Training Program and School Teachers worked collaboratively, composes some numbers of Lesson Studies. The grounds of the Lesson Study activities were reflecting and promoting the new paradigm of the secondary mathematics and science education, in which learning activities are not only perceived pragmatically and short-time oriented but also to be perceived as a long-life time purposes. Lesson Study activities let the teachers to reflect and evaluate, in cooperation with lectures or other teachers, their paradigm of teaching. Approaches of Lesson Studies covered (a) students cooperation with others in their learning, (b) contextual teaching and learning, (c) life-skill, (d) hands-on activities, (e) interactive process oriented curriculum and syllabi development, and (f) teachers and students autonomous. From those three sites of study, there can be produced the notions of educational improvement, in term of teacher, student and lecture.

In general, the implementation of lesson study indicated improvements of (a) teachers' competencies (creativity, questioning skills, experiemental methods), and (b) teaching and learning processes, and (c) students' activities, motivation, enthusiasm and performances.Besides, the project also resulted in the developments of CAIs for Chemistry, authentic assessment methods, student worksheets, and constructivist approach. However, the evaluation also identified that: (1) teachers have varied in their perceptions of the new paradigm of mathematics and science education; (2) the new approaches take much more time than conventional ones; (3) Enculturing innovation needs time; (4) the existing curriculum is found to be too crowded; (5) the existing class is still too big for the new approaches; (6) most teaching and learning processes were still oriented to the exit national exam; and (7) teachers were resistent to changes. However, its contribution to the accountability and sustainability of educational development is still a crutial issue.

II. LESSON STUDY SUPPORTS EDUCATIONAL REFORM

Under cooperation between Government of Indonesia (GOI) and JICA-Japan, three universities UPI Bandung, UNY Yogyakarta and UM Malang carried out project called IMSTEP-JICA for pursuing good practice of mathematics (and sciences) teaching by empowering and developing teacher education. Starting in 1999 and lasting in 2005, the extending of the project resulting piloting activities through Lesson Studies for good practice of secondary mathematics teaching in three cluster site West Java, Central Java and East Java. Results of the studies significantly indicated that there are improvements of the practice of secondary mathematics teaching learning processes in term of teaching methodology, teacher competencies, students achievements, alternative evaluation, teaching learning resources and syllabus. However, some misconceptions of counterpart made Lesson Study through IMSTEP was not effective yet. The following Lesson Study activities were conducted under the schema of SISTTEM, stand for Strengthening In-Service Teacher Training of Mathematics and Science Education at Junior Secondary Level, was born from the cooperation between JICA (Japan International Cooperation Agency) and MONE / Depdiknas (Ministry of National Education / Departemen Pendidikan Nasional) of Indonesia. The Overall Goal of SISTTEM is to develop the model of in-service teacher training primarily through MGMP activities applying lesson study; to continue teacher professional development in the target province; and to improve the level of student learning ability in mathematics and science in the target districts. At the national level, the *Lesson study* project can be a statewide movement for professional development of primary and secondary education. Through IMSTEP and SISTTEM, since 2001, DGMPSE (Directorate General of Management of Primary and Secondary Education, in cooperation with JICA-Japan, has initiated Lesson Study as a model of professional development designed to assist teachers produce quality lesson plans and gain a better understanding of student learning in primary and secondary mathematics and science.

A. Lesson Study is the Way to Reform Teaching Practice

Previous study by IMSTEP indicated that to encourage mathematics teachers' professional development, all sides in educational system should consider the promotion of: (1) good atmosphere for teaching and learning, (2) various teaching methods and teaching learning resources, (3) chances for the teachers and their students to perform their initiatives, (4) cooperative learning, (5) research class as a model for educational innovations (as Japanese teachers do), (6) teachers' role to develop their curriculum, (7) school and teacher autonomy (8) school-based management, and (9) contextual teaching. Since the early of 2000, there are cooperations among universities, teacher training institutes and MoNE's Directorate of Secondary Education to improve teachers' competencies to support the implementation of the proposed competent-based curriculum (Curriculum 2004).

Government agenda for implementing the new curriculum lead to the need for socialization the philosophy and the concepts of school-based curriculum as well as the results of lesson Study activities. Such socializations and workshops in which results of Lesson Study had been socialized. In the fiscal year 2001-2003, a medium scale of piloting of Teaching Learning Model of secondary mathematics and sciences through Lesson Study has been carried out by IMSTEP-JICA in collaboration with UPI Bandung, UNY Yogyakarta, and UM Malang, in which Japan Government supported facilities, training as well as Educational Experts.The objectives of the Lesson Study activities were to contribute the improvement of secondary mathematics education by pursuing good practice of mathematics teaching. Lesson Studies for secondary mathematics were carried out by mainly Classroom Action Research approach. Teachers carried out to improve the teaching learning practices and to find more appropriate methods for facilitating students learning. Teachers' experiences have been shared with other teachers and the lectures. The specific objectives of Lesson Study activities are: (1) to develop instrument and equipment for teaching learning process, (2) to develop teaching method and model for teaching learning process, (3) to develop teaching material for teaching learning process, and (4) to develop teaching evaluation for teaching learning process.

The results of Lesson Study could be inferred from the view of students, teachers, and of lecturers. Evidences were collected through observations, questionnaires and interviews. Teachers perceived that Lesson Study gave positive results because it could improve teachers' professionalism in finding variations of teaching approaches, and teaching methods. It introduced the new model of teaching in which teachers were able to increase the variation of alternatives on how to conduct classroom teaching and learning process. There were evidences that Lesson Study improved teachers' skill to communicate, to deliver questions, to carryout discussion as well as teachers' creativity. Teachers perceived that Lesson Study activities were useful to support the implementation of competence-based curriculum. Research conducted by SISTTEM found that Lesson Study through IMSTEP have two fundamental limitations i.e. problems observed in the follow up period and, challenges newly emerging in the forthcoming program. In the first place, one of the observed tasks throughout the follow up period is how to deepen the quality of LS. Observing and understanding realities and facts of students' learning and reflecting lessons based on such evidences are really difficult to conduct. The viewpoints of counterparts of IMSTEP tended to address only "how teachers teach" and fail to scrutinize "how students learn". The limitations in observers' viewpoints and positions are likely to limit the directions of discussion in teaching, rather than learning of students. Moreover, reflection tends to finish with criticism against the teachers who have opened their lesson for observation, not fostering learning from the observed practices. However, if teachers cannot develop learning relationship among themselves, LS will become a place for teachers only to "bash" each other for their faulty practices.

Under the schema of SISTTEM, Lesson Study were carried out in three different sites i.e. in Kabupaten Sumedang (West Java), Kabupaten Pasuruan (East Java), and Kabupaten Bantul (DI Yogyakarta); they jointly carried out by the Indonesian counterpart team and the JICA Expert Team in cooperation with the three universities, i.e. UPI, UNY and UM, which were the counterparts of the IMSTEP. In this schema, Lesson study is defined as a practice-oriented method for improving teaching skills by teachers themselves; in which, it usually includes: developing lesson plans (planning), practicing the lesson plans in real classes while peer teachers observe the lessons (open lesson), and reflecting on the lessons together to give feedback to the teachers (reflection). To implement Lesson Study, SISTTEM employs the results of previous schema i.e. IMSTEP especially in term of human resources. SISTTEM carries out some trainings for schools principals, leader of MGMP (teachers club), and supervisors. The content of training covers the concept of learning community, lessons study, and lessons innovation. The implementation of Lesson Study at entire school level is scheduled for two and a half years i.e. May 2006 -October 2008.

B. Lesson Study is to Reform Mathematics Teaching

In the first research of lesson study (Marsigit, 2007) the aim was to picture of mathematical thinking that is students thinking on the concept of Lowest Common Multiple (LCM) at the 4th Grade Students of Primary School in Indonesia. With the ground of the New School-Based Curriculum we, in collaboration with teacher, prepared teaching learning of LCM with Realistic Approach. The search in this lesson study strived to uncover the idea of mathematics as a human activity that is stressed in realistics approach. Teacher organized the class as a process of *guided reinvention* (De Lange, 1996, in Zulkardi, 2006) that is to step in learning LCM by developing instructional environment e.g. let the students to freely chose and develop their methods and aids to solve the problems. The teacher let the students to work individually and in group less formally to perform horizontal mathematization; and then anticipating the structure to more formal raise mathematization activities.

From the analyses of videotaped lesson, it was indicated that the students strived to develop horizontal mathematization through some activities. The students strived to represent daily problems in a related mathematical formula and strived to prove regularities of consisting concepts. Some students performed vertical mathematization by employing different models and formulated mathematical model to solve the problems. The striking results of the study illustrated that : 1) Students' thinkings of the concept of LCM were much contributed by teacher's employing real-life contexts as a starting point for their learning; 2) Students' thinking of the concept of LCM simultaneously affected by the use of their own productions of formulas and strategies; 3) In thinking the concept of LCM, interactions between teacher and students, students and students are the essential activities; and 4) Students' thinkings of the concepts of LCM were influenced by the connection among the strands of mathematical concepts developed previously e.g. the concept of factor of numbers and by the connection with meaningful problems in the real world.

The second research of lesson study (Marsigit, 2008), the aim is to reflect the promottion of students to develop mathematical method in learning the total area of a right circular cylinder and sphere, and the volume of a right circular cone. Specifically, the expected results of the research is to describe students' attempts or efforts in Katagiri S. (2004): inductive thinking, analogical thinking, deductive thinking, integrative thinking (including expansive thinking), developmental thinking, abstract thinking (thinking that abstracts, concretizes, idealizes, and thinking that clarifies conditions), thinking that simplifies, thinking that generalizes, thinking that specializes, thinking that symbolize, thinking that express with numbers, quantifies, and figures. At small group discussion Students learned that the lateral area of right circular cylinder is equal to the area of its rectangle i.e. mathematical thinking of analogy of concept and induction). Students learned that the total area of right circular cylinder is equal to the area of its rectangle plus the area of its two circles i.e. mathematical thinking of analogy of concept and induction.

In developing teaching learning methods, the teachers need to: plan the scenario of teaching, plan students activities, plan teachers' roles, distribute the assignments, develop assesment methods, and monitor the progress of students achievements. To develop their experiences, the teachers also need to participate frequently in such kinds of workshops or seminars. By using those teaching materials teachers could conduct the teaching and learning process more efficiently. Students enjoyed their learning process because they were involved in observing and doing things. Those teaching materials also improve students' motivation and interest in learning the materials. Although there were may kinds of teaching materials that have been developed through those Lesson Study activities, there still more topics that need to have or to have better teaching materials. Therefore lecturers from three universities need to have further collaborative work to develop more teaching materials in the future.

Further, the study also recommended that to improve the quality of mathematics and sciences education, the central government needs to: (1) implement more suitable curriculum i.e. more simple and flexible one, (2) redefine the role of the teachers i.e. teachers should facilitate students' need to learn, (3) redefine of the role of principals; principals should support the professional development of teachers by allowing them to attend and participate in scientific, meetings and trainings, (4) redefine the role of schools; schools should promote school-based management, (5) redefine the role of supervisor; the supervisors need to have similar background with the teachers they supervise in order to be able to do academic supervision, (6) improve teachers' autonomy to innovate mathematics and science teaching and learning, and (7) promote better collaboration between school and university; communication among lecturers and teachers should be improved; these could be done through collaborative action researches and exchange experiences through seminars and workshops, (8) redefine evaluation system, and (9) to extend project for promoting new paradigms and educational innovations.

The Lesson Study project was proven to be very effective in lifting students' enthusiasm in learning science, helping students to develop their experimental and discussion skill, giving opportunities to students in developing their own scientific concept by themselves. It was also reported that by using constructivism approach, the students may find out their best style of learning. Competition rises among groups of students in presenting the results of their work and defending their presentations. This forces students to learn theory more on their own. As a result of Lesson Study activities there were many teaching material developed either by lecturers and teaching together or by lecturers or teachers themselves. Those materials were either developed by lecturers or teachers in their own classroom or by lecturers and teachers together during Lesson Study activities. In general lecturers and/or teachers developed the teaching materials after thinking extensively what and how to develop teaching materials for a certain topic, and then develop the materials. Further they try out the teaching materials in their classroom and revise those according to the result of the try out.

C. Lesson Study Develops Learning Community

Successful implementation of SISTTEMS has promoted and attracted educators and education institutions across the archipelago to perform it. The Ministry of National Education (MONE) under the auspecies of JICA through PELITA (Peningkatan Kualitas Tenaga Pendidikan SMP/MTs or the Improvement of Junior High School Teachers) extended the piloting of lesson study from 2009 to 2013 in the following three other districts/cities: Padang City under the supervision of State University of Padang in Sumatra island, the Banjar Baru District under the supervision of University of Lambungmangkurat in Borneo island, and the North Minahasa District under the supervision of State University of Manado in Sulawesi island. MONE has also initiated to facilitate 52 TEIs all over the country to implement lesson study for improvement of pre-service program since 2008. In addition, Indonesia University of Education has succeded dissemination of lesson study in 16 districts of West Java

Provinces through school-university partnership project. Now, Jambi Province in Sumatra island is interrested to adopt West Javas' success story of lesson study.

In Yogyakarta the Lesson Study began with a limited number of schools and teachers of mathematics and sciences only, but has expanded to reach more schools and teachers of other subjects. Involvement of MGMP, which stands for Musyawarah Guru Mata Pelajaran. MGMP is organized in each kabupaten/kota and the MGMP Committee members are elected from among member teachers. The Committee consists of Chairperson, Secretary, Treasurer, Coordinator for activity program, Coordinator for material development, amd Coordinator for Reporting/Publication. The MGMP activities have been arranged as follows: Monday for Civics, Indonesian Language, and Religious Education; Tuesday for English; Wednesday for Mathematics; Thursday for Social Studies, History, Geography, Economics, Anthropology; Friday for no LS activity; and Saturday for Science, Chemistry, Biology, Physical Education.

The MGMP-based lesson study was conducted in 2007, participated by 331 JHS teachers of Mathematics and Science from 34 JHSs located in 17 sub-districts of the Bantul District. The activities were organized as follows: teachers of Mathematics met once in two weeks on Thursday (08.00-13.00), while teachers of Science on Saturday with the same duration. These teachers conducted the Lesson Study in eight home bases, with each home base being supervised by two teacher educators from Yogyakarta State University.

It is non-structural organization of teachers, whose esablishment is stipulated in the Government Regulation No. 38/1994 on Education Personnel. It is a professional forum for subject teachers at the kabupaten/kota (district/city) level. According to the guidelines issued by the then Directorate General for Primary and Secondary Education, Ministry of National Education (now the Ministry of Education and Culture). Through lesson study activities, MGMP has noted some achievement of teachers' professional development: encouraging of teachers to improve theri ability and skills to plan, implement and evaluate teaching and learning activities; developing of discussion activities to solve the problems faced by teachers to carry out their daily responsibilities and to propose solutions in accordance with the characteristics of the subject matter teachers, school conditions, and communities; providing teachers with opportunities to share information and experience about the curriculum implementation and the development of science and technology; providing teachers with opportunities to ex[ress their ideas at MGMP meetings to improve their professional skills; and developing cooperation with other institutions to develop a conducive, effective and enjoyable teaching and learning processes.

In Yogyakarta the Lesson Study began with a limited number of schools and teachers of mathematics and sciences only, but has expanded to reach more schools and teachers of other subjects. This is summarized in the Table 2 below.

Table 2: Data on the Developments of the Lesson Study in Yogyakarta

Year	Number of Schools (JHS and SHS)*	Subjects Studied	Comment
2001	21	One school for one subject only	Piloting Lesson Study simultaneously supported by Teaching Material development at University It seemed to emerge the culture of collaboration and communication among faculty members
2002	42	One school for one subject only	
2003	3 JHSs + 3 SHSs	Mathematics and Basic Sciences in each school	In this phase, the data were collected as the results of monitoring the Piloting
2004	105 new schools in one regency	Mathematics, Natural Sciences, Biology, English, Social Science, Javanese Language, Civics, Islamic Religion, Art and Culture, Physical Education	Involvement of Subject Teachers' Organizations It seemed to emerge the commitment of all sides to implement Lesson Study
2005	115 school in two regencies	The new scheme of : Plan-Do-See was developed i.e. one Plan for some Do	The new scheme is perceived as local creativity. It seemed to emerge the culture of collaboration among the teachers
2006	All public and Islamic JHSs in the Bantul Regency	Up to the devastating earthquake	Due to the earthquake, the culture of collaboration among the teachers was extended and intensified. Islamic School-based Lesson Study is perceived as

			nurturant effect of the implementation of Lesson Study.

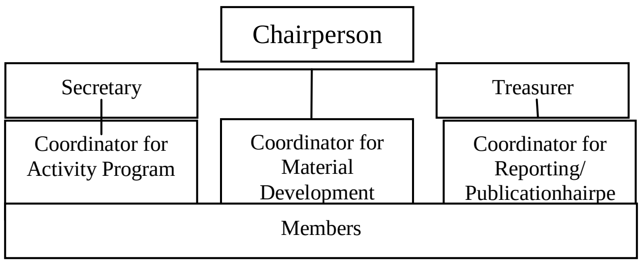
*) JHS = Junior High School; SHS = Senior High School

Table 2 shows the involvement of MGMP, which stands for *Musyawarah Guru Mata Pelajaran*. It is non-structural organization of teachers, whose esablishment is stipulated in the Government Regulation No. 38/1994 on Education Personnel. It is a professional forum for subject teachers at the *kabupaten/kota* (district/city) level. According to the guidelines issued by the then Directorate General for Primary and Secondary Education, Ministry of National Education (now the Ministry of Education and Culture). MGMP has five objectives:

1. To encourage teachers to improve theri ability and skills to plan, implement and evaluate teaching and learning activities;
2. To discuss problems faced by teachers to carry out their daily responsibilities and to propose solutions in accordance with the characteristics of the subject matter teachers, school conditions, and communities;
3. To provide teachers with opportunities to share information and experience about the curriculum implementation and the development of science and technology;
4. To provide teachers with opportunities to ex[ress their ideas at MGMP meetings to improve their professional skills; and
5. To develop cooperation with other institutions to develop a conducive, effective and enjoyable teaching and learning processes.

As mentioned before, MGMP is organized in each *kabupaten/kota* and the MGMP Committee members are elected from among member teachers. The Committee consists of Chairperson, Secretary, Treasurer, Coordinator for activity program, Coordinator for material development, amd Coordinator for Reporting/Publication. The MGMP organizational structure is illustrated in Figure 1 below.

Table 3 : The Organizational Structure of MGMP



The MGMP activities have been arranged as follows: Monday for Civics, Indonesian Language, and Religious Education; Tuesday for English; Wednesday for Mathematics; Thursday for Social Studies, History, Geography, Economics, Anthropology; Friday for no LS activity; and Saturday for Science, Chemistry, Biology, Physical Education.

III. LESSON STUDY PROMOTES TEACHERS' PROFESIONAL DEVELOPMENT

In the academic year of 2008/2009 up to the present time, the lesson study scheme has been developed. As has been mentioend before, it consists of three main steps: *Plan* (preparation), *Do* (Implementation and observation), and *See* (reflection/review). The Plan stage covers the following activities: reviewing the syllabi, developing the lesson plan, developing student's worksheets, developing the observation sheet, and preparing class management. The teachers do the planning through workshops. In the Do stage, one of the teachers in a group implemented the lesson plan, while other teachers observe. They observe what the teacher is doing, what the students are doing, the teacher-students and student-student interaction patterns, the students' activities either as their being responsive to the teacher tasks and as initiators. In the See Stage, teachers are involved in a meeting attended by model teachers, supervisors, oberevers, and stakeholders. This meeting is aimed at providing the participants to reflect on the lesson implementation and then find ways of improving the teaching and learning quality. In the period oa April 2007 to June 2008, each Lesson Study Home Base carried out 12 Lesson Study activities as planned. Since the results were found promising, a new scheme was developed, i.e. 3-4 Plans to be followed by 6-7 Do and See activities.

The lesson study activities covered developing teaching materials and utilized a mathematical modeling of the disaster processes and impact so that students could learn both mathematics and the nature of the disaster. The Lesson Study activities proved to be effective in lifting students' enthusiasm in learning science, helping students to develop their experimental and discussion skills, and in giving opportunities to students in developing their own scientific concepts by themselves. It was also reported that by applying the constructivism approach, the students could find out their best style of learning. Competition rose among groups of students in presenting the results of their works and in defending their presentations. This forced students to learn more theory for their own sake. As a result of Lesson Study activities there were many teaching materials developed either by lecturers or by teachers. Those materials were either developed by lecturers or teachers in their own classrooms or by lecturers and teachers altogether during Lesson Study activities. In general, lecturers and/or teachers developed the teaching materials after thinking extensively what and how to develop teaching materials for a certain topic, and then developed the materials. Further, they tried out the teaching materials in their classrooms and revised those based on the result of the try out. Success stories of the implementation of the lesson study to the teaching of mathematics and science have encouraged teachers of other subjects to implement it in their classrooooms. This has changed the ways teachers and students think and do during the teaching and learning processes. They become ready to learn from one another and share what they have learned for more effective learning. In short, improvement has been achieved together and the achievement has been achieved collectively.

To provide evidence of the lasting impact of the lesson study activities, a research study has been conducted in 2013. In this study data on the impact of the lesson study activites were collected through questionnaires to be filled in by teachers, students, and principals, interviews with teachers, students and principals, observations of the lesson study activities cycles, and achievement testing. Through lesson studies activities, the indicators of teachers' professional development seemed to be improved, i.e.: teachers participation 60% – 75 % , the teachers be more concerned about their students differences; the teachers strived to facilitate students activities; the teachers employed various method of teaching; the teachers employed various method of evaluation; the teachers strived to connect the relationship among Subject-Matter; the teachers developed Contextual Teaching Learning (CTL) approach; the teachers developed various interaction; the teachers employed small group discussion; the teachers developed the scheme for competences achievement; the teachers facilitated their students to be more active; the teachers employed various teaching aids; the teachers employed various learning resources; the teachers strived to implement new paradigm of teaching; the teachers were more passion to facilitate their students; the teachers have their habit to reflect their experiences of teaching; the students were more interested to learning object; the students were more motivated to engage in teaching learning processes; the students were more active in the class.

With these findings, both teacher educators and teachers may be more convinced that improvements in both pre-service and in-service teacher education may be achieved through the Lesson Study strategy by empowering the MGMP. Lesson Study was to be perceived as a useful and effective framework to develop teachers professionalism by performing their accountability and sustainability of teaching, through collaboration among the sides of educational practices consist of teachers, supervisor, lectures and stakeholders. The seminar on the results of the lessson study activities have been found useful as a means of: sharing the results of the lesson study for all groups, teachers, lecturers, and stakeholders; sharing any common problems found during thelesson study implementation; sharing any good solutions to the above problems, and reporting and sriting the finasl resutls of the lesson study implementation as well as its possibility to expand it into a wider scope of both teachers and schools.

IV. LESSON STUDY AND CURRICULUM DEVELOPMENT

In the School-Based Curriculum, it was stated that mathematics in primary and secondary school should encourage the students to think logically, analytically, systematically, critically, creatively and be able to collaborate with others. The implementations of primary and secondary mathematics curriculum in class-rooms need to develop problem solving skills covering both closed and open problems. In solving the problems, students need to creatively develop many ways and alternatives, to develop mathematical models, and to estimate the results. Contextual and realistic approaches are recommended to be developed by the teachers to encourage mathematical thinking in primary schools. With these approaches, there is a hope that the students step-by-step learn and master mathematics enthusiastically. To make their teaching learning of primary mathematics more effective, teachers also need to develop resources such as information technology, teaching aids and other media.

The curriculum outlines the aims of teaching learning of mathematics are as follows: (1) to understand the concepts of mathematics, to explain the relationships among them and to apply them to solve the problems accurately and efficiently, (2) to develop thinking skills to learn patterns and characteristics of mathematics, to manipulate them in order to generalize, to proof and to explain ideas and mathematics propositions, (3) to develop problems solving skills which covers understanding the problems, outlining mathmatical models, solving them and estimating the outcomes, (3) to communicate mathematics ideas using symbols, tables, diagrams and other media, and (4) to develop appreciations of the uses of mathematics in daily lifes, curiosity, consideration, and willingness to learn mathematics as well as tough and self-confidence.

A. Developing the Scheme

National Standard of Education suggests that the teachers need to develop their teaching in such that their students are able to learn mathematics optimally. It also encourages the teachers to develop various methods of teaching; they are expected to develop teaching aid, student's work sheets, and assessment method. Teachers need to be able to facilitate students' learning mathematics. Therefore, contextual teaching approach and realistic approach are recommended to be used. As the impact of government programs to innovate education and international trend of educational reform, the teachers are also expected to develop many kinds of educational research. Observing students' behaviors when they interacts with surrounding objects or people, may be the starting point to discuss about the mechanisms of their mathematical thinking. In the classroom activities the students may look at the object, take hold of it, listen to the sound or talk to the people; more than just these, she may also categorize, memorize or even make the plan for a certain mathematical thinking. Such behavior is taken for granted, much is automatic, yet for it happen at all requires the utilization of complex cognitive processes.

A series of Lesson Study activities may be thought of as constituting a set of culturally organized activities carried out by teacher or a group of teacher to promote children's mathematical thinking. Many small group activities are flexible and do not have a clear end point, predetermined by the teacher. However, small group discussions offer an interesting context in which to explore the participation of children interacting among the others in naturally occurring open ended thinking. In general, when a task has a clear end point, it has been assumed that the children were thinking towards that point. These series of studies were particularly interested in the attitude and method to which the students develop mathematical thinking to learn mathematics. Experience indicates that teachers can employ Lesson Study to promote mathematical thinking. Teacher is perceived to be the subject of the research as well as to be the researcher. By proposing planning, doing and seeing, the study expected to uncover the aspects of students' mathematical thinking.

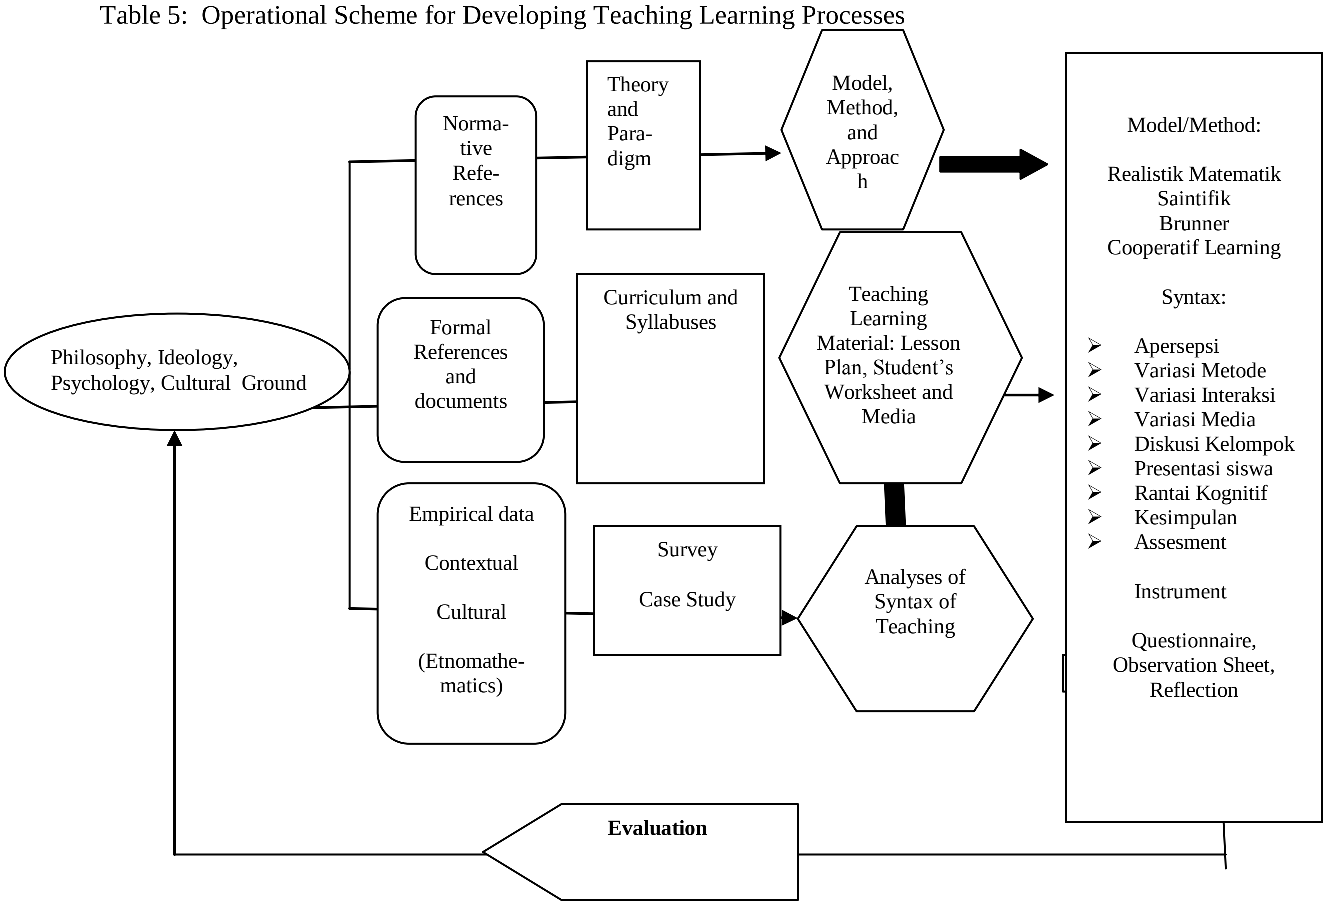
B. Implementation

Students' interactions with adults and among themselves may promote complex cognitive processes in the form of mathematical thinking. The context in which tasks are performed has begun to form a significant aspect of analysis, it has been interpreted in a variety of ways, sometimes in very local terms, to refer to the conditions under which a particular task is performed, or a particular mathematical thinking is produced. A wider view suggested that the aspect of students' mathematical thinking offers a variety of potential meanings and interpretations, and that mathematical thinking involves a negotiation of shared context. Mathematical thinking happens in the context of teaching learning processes. Group discussion based on principles of promoting children's growth and development through play activities may encourage the students to explore, experiment, question, and talk. Teacher's efforts to facilitate their students to find various patterns of mathematical content can be seen as consistent with extending the students' experiences of mathematical thinking and encouraging social interaction among them.

Table 5: Operational Scheme for Developing Teaching Learning Processes



Marsigit (2010) aimed the study of lesson study to promote *mathematical thinking* of primary and secondary students. The study provided teachers the opportunity to see teaching and learning in primary and secondary mathematics classroom in a real context. The study guided the teachers to focus on planning, implementation, observation, and reflection of their mathematical teaching in such away that their students were to perform *mathematical thinking*. By looking at real contexts of mathematical teaching learning processes, the researcher and the teachers were able to develop a common understanding of what should be planned, done and reflected to promote mathematical thinking. The study also provided opportunities for teachers to carefully examine students' *mathematical thinking* by observing and discussing real mathematics problems. The study was in the form of *School-Based Lesson Study* in which some teachers of Primary and Secondary Schools were participated to establish lesson study goal and develop lesson study cycles by developing common vision of systematic and consistent pedagogical approach to facilitate students need in performing their mathematical thinking. The steps of developing School-Based Lesson Study covered recruiting teachers, developing the theme, planning the Lesson Study, preparing observation and reflecting the results.

1. First Lesson

At the first lesson study activities composed of 4th-grade teachers and 5th-grade teachers of Primary Schools and 8th-grade teachers of Junior High Schools who work in three different schools: SD MIN I Yogyakarta, SD Percobaan Bulaksumur Yogyakrta and SMP N II Depok Yogyakarta. The researcher facilitated the teachers to provide perspective and a broader view of the issues as well as to serve as outside commentator, evaluator, or outside advisor. The researcher emphasized that the selected teachers should come in with the mindset of being a learner and ready to share and to communicate findings. The researcher and the selected teachers built open communication and set time-table for the related activities. The lesson study theme captures the school goals as well as the academic content goals for students to develop approaches and to perform *mathematical thinking*. The researcher exposed the important of mathematical thinking in the sense of students' thinking, educational theories, and international trends. The selected teachers choose a subject area in which to focus on *mathematical thinking*. They needed to identify a unit or lesson on which to focus on *mathematical thinking* and thoroughly discuss the unit and agree about what they are trying to achieve with the lesson. They also needed to expect what did they want students to know and be able to perform mathematical thinking. The researcher strived that the selected teachers must understand how their lesson would significantly supporting and facilitating mathematical thinking. To achieve this goal the researcher carried out firstly the socialization of Katagiri's notions of mathematical thinking. Prior the study implementation, the researcher shared and discussed with the teachers to prepare lessons related to the topic. The researcher and the selected teachers developed the lessons and set the stage for the observation in which the lesson and the learning processes would be reflected. A piece of planning the lesson included the schema of student responses to various aspects of the lesson and preparing appropriate teacher responses as well as the logical implication of mathematical thinking.

There was conformity among the goal of the overall Lesson Study, the aim of teaching and the aim for student learning. The researcher and the selected teachers developed lesson design and lesson plan to bring these goals. The developed Lesson Plan referred to the School-Based Curriculum (KTSP). The selected teachers implemented teaching learning processes while the researchers collect data on students' mathematical thinking and their aspects. Some other teachers and the researcher were set to observe the study lesson in a scheduled time and place. The researcher and the selected teachers shared the data collected covering of the evidence that goals for promoting students' mathematical thinking; and then found out the solutions of how to improve the lessons. Lesson debriefing was proposed to give the chance for the selected teacher to reflect his/her teaching; while getting inputs from other teachers or researcher. In while teaching, the researcher collected the data that need for debriefing. The data covered the comments of students and the work students produce during the lesson. At some occasions the researcher needed to observer closely the work and comments of particular students. The researcher and the selected teachers prepared copies of the lesson plan, teaching aids, and any students' worksheets that students would be using. The study prepared the classroom so that the observers can circulate freely among students during whole-class teaching. The researcher developed instrument to investigate the structure of lesson, the schema of interaction, and the schema of mathematical thinking in the frame of the effort of achieving the mathematical competences.

It was not always easy for the teacher to start initiating the students to think mathematically on the problems of understanding the Least Common Multiple (LCM) and determining the Least Common Multiple (LCM). At a certain occasion, the students seemed to not be able to grasp teacher's expectation of *mathematical thinking*. When the students were not able to take examples, the teacher posed the prepared problems. In group discussion, *mathematical thinking* was always started when the teacher posed the prepared problems written in the Work Sheet. There was a high spirit when the students found out the relevant references and resources to solve the problems. The students employed their pre-requisite knowledge of Calendar to find the pattern and relation i.e. from the problem of finding *the multiple of 7 days and the multiple of 8 days in one year.* Additional skill might have been a supporting factor that the students by themselves employed various aids to solve the problems such as calendar, hand-phone, and blank table prepared by the teacher. In the effort of identifying or describing the specific mathematics, the students found the routine activities there are the concept of addition and subtraction i.e. 7 + 7 + 7 + 7 …. or subtracting by 7 (for swimming); 8+8+8+8+8…. or subtracting by 8 (for gardening). The concept of "frequency" emerged when there was a question of " how many times common activities". The concept of "frequency" was interpreted as the concept of "repeating addition or subtraction" i.e. the concept of multiple of number such as - *For 10 month, Shinta goes to swim 10 x 5 = 50 times; - For 10 month, Shinta goes to gardening 10 x 4 = 40 times.* In the effort of schematizing, formulating and visualizing, the students employed different ways to indicate that there are various ways in determining the multiple number of 7 and 8 e.g. using calendar, using series of numbers, using calculator and manipulating different symbols for 7 and 8. The students employed different schemas on determining the common multiple of 7 and 8 i.e. some students calculate the multiple of 7 for the whole year first then multiple for 8; and followed by counting the number of common activities in one year. Some students indicated first the common multiple of 7 and 8 (i.e. 56) and then counting the number of common activities in one year.

In the effort of to think mathematically on the problems of understanding the Least Common Multiple (LCM) and determining the Least Common Multiple (LCM), the series of sentences produces by the group indicated first *horizontal mathematization* then followed by *vertical mathematizaion*. Most of the students employed subtraction, addition, multiplication and division to list multiple of 7 and 8. They indicated Common Multiple , as the mathematical concepts to answer the common Shintas activities in one year. Students' reflection of *mathematical thinking* employed transition from daily language of mathematical language i.e. from common activities to common multiple. There was a student who jumped their concept to LCM due to he got it from *"informal private lesson*". In performing the *Vertical Mathematization* the students need the assistances from the teacher. The teacher encouraged the students to list more the multiple of 7 and the multiple of 8 and encouraged them to indicate the common multiple of 7 and 8. In the effort of discovering relations, the students discovered the relationship between "common activities" and "common multiple" i.e. 7 days and 8 days compare with "multiple of 7 and 8 = 56". In the aspect of discovering regularities, the students found that the concepts of regularities arouse from the concepts of "routine activities". The students recognized the isomorphic aspect in different mathematics problems i.e. the regularities emerged from isomorphic activities such as "swimming" and "gardening", "study club", "laboratory activities" or "going to library". There are the key concepts reflecting by the key word of how the students can transfer the real world problems to mathematical problem e.g. the concepts of "common", "regular", "routine", "number of", etc. Students' thinking of the concept of LCM were much contributed by teacher's employing real-life contexts as a starting point for their learning and simultaneously affected by the use of their own productions of formulas and strategies. In thinking the concept of LCM, interactions between teacher and students, students and students are the essential activities. Students' thinking of the concepts of LCM were influenced by the connection among the strands of mathematical concepts developed previously e.g. the concept of factor of numbers and by the connection with meaningful problems in the real world.

2. Second Lesson

At the second lesson study activities The subjects of the study were the 5th grade students of Primary School. The aim of the research was to promote mathematical attitude through teaching learning the Volume of Cube and Rectangular Parallelepiped. The aim of the lesson was to encourage the students to find the volume of Cube and Rectangular Parallelepiped and applying them to solve related problems. The specific aim of the lesson were to find the volume of Cube and Rectangular Parallelepiped and to solve the problems related to the volume of Cube and Rectangular Parallelepiped. Most of the students strived very hard to understand the concepts of Pyramid, Prism, Cone and Cube (Lesson Object). There are some ways in which the students strive to understand the concept: manipulation of the Model of Three Dimensional Geometrical Object, questioning to the teacher, questioning to other students, manipulation of mathematics net. Some students got the concept of geometrical shapes from informal learning i.e. from their parents or from additional lesson outside the school. The students were able to indicate the similar of geometrical shapes in daily lives; they also tried to identify the function of identical geometrical shape in daily live. The students perceived that their teacher has important role in helping them to perform *mathematical thinking.*Different geometrical shapes have different level to be understood. The concept of a cone was the most difficult for the students to understand. The students have difficulties how to calculate the number of the side of the cone. To solve the problems some students delivered the questions to the teacher and the other asked to their classmates. The students tried to employ their pre-requisite knowledge in clarifying the difficult concepts. Some students developed the step in order to understand the difficult concepts i.e. by asking first about the nature of the concept of a cone and then to ask to the teacher about its characteristics. However, some students inevitably jumped without any pattern due to have no systematic knowledge of geometrical shapes. There were the students who tended to be silent and passive if they still do not understand the difficult concepts. Students' effort to understand the difficult concept of geometrical shapes depended on the context and the schema of teaching. If the teacher communicate with the students in less formal, the students felt have no constraint to ask to their teachers. Some students perceived that their teacher should provide the complete and good quality of teaching aids. However, they also perceived that they enjoy getting assignments from the teacher. Most of the students employ inductive thinking i.e. by trial and error to answer teacher's questions; some of them tried to sketch the geometrical shapes and compare with different size of the models. The students tended to re-state the explanations and get attention from their teacher and their classmates to confirm whether their ideas were true.

3. Third Lesson

At the third lesson study activities, the subjects of the study were the 8th grade students of Junior High School. The aim of the lesson was to understand the characteristics of cylinder, cone, sphere and to determine their measures. The specific aims of the lesson were to identify the formula of the total area of right circular cylinder and to identify the formula of the area of sphere. The students manipulated *Concrete Mode*l of the *Right Circular Cylinder, Sphere and Right Circular Cone* in order to identify its components. They performed *mathematical abstractions* when the teacher gave them some questions or when the teacher let them to work in group. Some students defined the *concept* of *Right Circular Cylinder* as its *functions* in daily life e.g. *"A Right Circular Cylinder is the storage to keep something like pen, pencil, etc."* There were students who defined *a Sphere* by giving the example in daily life e.g. ball, tennis-ball, etc. Students' *abstractions* of Sphere resulted the investigation of its components i.e. the *radius* and *diameter*. There were many ways in which the students *idealized* the geometrical concept. They mostly confirmed the concept to the teacher and asked to their mates. Sometimes they performed their *idealization* by commenting others work. Some students asked to the teacher why the *lateral area of cylinder is equal to the area of its rectangle* and why the *volume of cylinder is equal to three times the volume of its cone? Analogical thinking* happened when the students perceived that finding the lateral area of *Right Circular Cylinder* is similar to finding the area of its rectangle; and, finding the area of *Sphere* is similar to finding the area of its surface i.e. covering its surface by twisting around with the rope. In sum, the concepts of geometrical shapes are mostly perceived to be analogical with examples in daily life e.g. the *right circular cone was perceived* as a *traditional hat.* In performing their *analogical thinking* the students frequently used strategic terminologies such as *"similar to", "compare with", "the example of",* and *"the function of".* Students' *inductive thinking* involved *Concretization and method of abstraction* in the area of *problem formation* and *comprehension.* When the students, they who had known the certain concepts, were paced to perform *inductive thinking* they tend to reconfirm their concepts. *Inductive thinking* was spread from the beginning activities to the ultimate accomplishment when the students were paced to do so. The students developed *method of abstraction* to observe the given model of right circular cylinder and strived to identify the components of the right circular cylinder in order to define the concept of right circular cylinder. Students' *inductive thinking* were also related to *establishing perspective* in which the students employed concrete model to search the total area of right circular cylinder and brook-down the model of right circular cylinder into its components: two congruent circles and one oblong.

Logical organization of mathematical concept happened in all context of mathematical method: *idealization, abstraction, deduction, induction and simplification. Logical organizations* of mathematical concept can be indicated from the following example of students' questions: Why the lateral area of cylinder is equal to the area of its rectangle?, Why the volume of cylinder is equal to three times the volume of its cone?, What happened if we do not carefully cover the surface of the sphere in which we use the rope for twisting around?, and Is it true that that the area of the surface of sphere is equal to 4 times the area of its circle? Problem *formation* and *comprehension* emerged when the students: observe given model of right circular cylinder, observe given model of Sphere, and observe given model of right circular cone; identify the components of the right circular cylinder, sphere and right circular cone; define the concept of right circular cylinder, sphere and right circular cone; and get questions and notices from teacher to search the concepts. The evidences indicated that, in term of the realistic approach, mathematical thinking can be performed through identifying or describing the specific mathematics, schematizing, formulating and visualizing a problem in different ways, discovering relations, discovering regularities, recognizing isomorphic aspect in different problems; transferring a real world problem to a mathematical problem. Mathematical thinking was always started when the teacher posed the prepared problems written in the *Work Sheet*. The students employed their pre-requisite knowledge to perform mathematical thinking. The students employed different ways to perform *schematizing, formulating* and *visualizing.* The series of sentences produces by the group indicated first *horizontal mathematization* then followed by *vertical mathematizaion*. In performing the *vertical mathematization* the students need the assistances from the teacher.

The students recognized the *isomorphic aspect* in different mathematics problems i.e. the key concepts reflecting by the key word of how the students can transfer the real world problems to mathematical problem. Students' thinking of the concepts of mathematics was influenced by the connection among the strands of mathematical concepts developed previously. The students tried to employ their pre-requisite knowledge in clarifying the difficult concepts and developed the step in order to understand the difficult concepts. Most of the students employ *inductive thinking* i.e. by trial and error to answer teacher's questions; some of them tried to sketch the geometrical shapes and compare with different size of the models. The students tended to re-state the explanations and get attention from their teacher and their classmates to confirm whether their ideas were true. There were many ways in which the students *idealized* the geometrical concept. Students' *inductive thinking* involved *concretization and method of abstraction* in the area of *problem formation and comprehension.* When the students, they who had known the certain concepts, were paced to perform *inductive thinking* they tend to reconfirm their concepts. *Inductive thinking* was spread from the beginning activities to the ultimate accomplishment when the students were paced to do so. Students' *inductive thinking* were also related to *establishing perspective* in which the students employed concrete model to search the total area of right circular cylinder and brook-down the model of right circular cylinder into its components: two congruent circles and one oblong. *Logical organization* of mathematical concept happened in all context of mathematical method: *idealization, abstraction, deduction, induction and simplification. Problem formation* and *comprehension* emerged when the students observe mathematical models.

V. RESULTS

The implementation of the lesson study proves the improvement of teaching mathematics and teachers professional development. Lesson study activities promotes the new perspective of teaching in term of its philosohy, ideology, psychology and cultural ground. This has changed the ways teachers and students think and do during the teaching and learning processes. They become ready to learn from one another and share what they have learned for more effective learning. In short, improvement has been achieved together and the achievement has been achieved collectively. The impact of the lesson study activites to mathematics teachers covers its readiness and its competencies of teaching i.e. the validity of its lesson plan and students worksheets, students' motivation and apperception, flexible method and approach of teaching, small group discussion, various method of teaching, various media, various interaction, teaching scheme, assessment, students' reflection, students' initiation, and students effort in constructing their mathematical concepts. With these findings, both teacher educators and teachers may be more convinced that improvements in both pre-service and in-service teacher education may be achieved through the Lesson Study strategy by empowering the MGMP. It can be concluded that through lesson study, the teachers are to perform better in managing classroom and in promoting their professional development. The teachers have the clear picture on the effective framework to develop teachers professionalism by performing their accountability and sustainability of teaching, through collaboration among the sides of educational practices consist of teachers, supervisor, lectures and stakeholders. Good athmosphere for teaching innovation can be maintained through various activities e.g. by sharing the results of the lesson study for all groups, teachers, lecturers, and stakeholders; sharing any common problems found during thelesson study implementation; sharing any good solutions to the above problems, and reporting and sriting the finasl resutls of the lesson study implementation as well as its possibility to expand it into a wider scope of both teachers and schools.

The Scientific Approach To Higher Education:

Examples From Physics Education Research

Allen Price
Emmanuel College, Boston U.S.A.

Economic development hinges on the scientific and technical preparation of future workers. In particular, training in physics teaches critical thinking, quantitative reasoning, and hands-on technical skills. It is obvious that the adequate preparation of teachers of science is essential. In spite of its importance, the traditional preparation of students in the field of physics has been found to be inadequate in teaching conceptual knowledge (Hake, 1998). While Indonesia has made great strides in improving literacy and school enrollment (Ahlburg, 1997), teaching methods have not evolved at the same pace. Whereas university level education in the fully developed economies is moving to a more student oriented mode, the Indonesia classroom remains more teacher centered (Frederick, 2011).

Many emerging economies, including Indonesia, have called for improved science education. Indeed, studies show that pedagogical reform can be cost effective in improving learning in the emerging economies (Kremer, 2013). Indonesia has experimented with such educational improvements as hands-on experimental kits for primary and secondary school classrooms (Zurcher, 2013), as well as professional development innovations, such as lesson study (Suratno, 2013; Saito, 2006). Some programs have been partnerships between schools and universities (Saito, 2007). However, the majority of these experiments in reform have been aimed at improving primary or secondary education, indicating a need to examine methods at the university level.

Yogyakarta State University (UNY) has a history of involvement in educational reform and experimentation. Faculty at UNY were directly involved in experiments in reform in science education at the secondary level (Saito, 2006; Saito, 2007). The University has one of the most respected teacher training programs in Indonesia, as well as technical programs of study in the field of physics. In addition, the city of Yogyakarta is a center of higher education in Indonesia, with several institutions of higher learning, thus giving access to many educators and professionals in the field of higher education in Indonesia.

Properly used, hands-on activities have been shown to increase conceptual learning (Hoellwarth, 2005). The topics of motion, mechanics, basic electric circuits, and optics can be effectively demonstrated with simple and often readily available components. See Gupta, 2010 (web link available in references listed at end of proposal) for an inspiring example of how this can be achieved in an emerging economy. Designed to be simple in execution, but conceptually engaging, each activity challenges students to solve a problem or to explain a simple demonstration. For example, one lesson in optics requires students to place a small mirror on the wall so that they can see the image of a piece of tape on their knee in the mirror. The solution (placing the mirror exactly halfway in height between the knee and eyes) requires a working understanding of the principles of reflection and geometry. Some example activities and required materials are listed in the table below.

Topic Of Activity	**Required Materials**
Free fall	String, washers or nuts
Projectile motion	Ball, pieces of tape
Circuits	Battery, short piece of bare wire, small light bulb
Reflection	Piece of mirror, tape

The choice of activities and how they are used in the classroom must be done with the guidance of experienced faculty. The implementation of these activities requires extensive interaction between instructor and small groups, as well as Socratic questioning. Initially, these techniques may not fit the cultural expectations students have of the classroom dynamic. To foster acceptance, the goals and expectations of the activities must be clearly explained to both students and instructors, and the cultural norms of behavior in the classroom must be respected. In addition, any written materials must be reviewed by before administering to reduce possibilities for misunderstanding.

In addition to hands-on inquiry group activities, there are other methods such as pre/post testing (in which student conceptual gains are measured), “just-in-time” teaching (in which pre-class online quizzes are used to guide in-class use of time), and peer-instruction (in which students debate amongst themselves solutions to conceptual questions). Hands-on activities make use of simple and inexpensive materials. Students work in small groups and often report in evaluations that these activities are the most memorable parts of the course for them.

Courses can be structured in a non-traditional format: students work in small groups with hands-on experiments and group problems. Students construct their own explanations of their observations and then debate them in a classroom environment, with the instructor playing the role of moderator.

Understanding which methods are successful and how to implement them will require a science of learning. Fundamental studies must reveal how the brain learns and in particular, how the mind applies concepts in physics, both correctly and incorrectly. Researchers are now developing this science which can only improve our ability to effectively teach at the university level.

Current Trends In Active Learning In The Sciences

Ana R. Otero
Emmanuel College, Boston U.S.A.

Indonesia has made great strides in improving access to education for its people. Indonesia is in the midst of educational reform, and faculty members at UNY, have been an active participant in this reform (Saito, 2007). Increasing interest and skills in the fields of science is imperative in a country like Indonesia that is rapidly industrializing. Therefore, it is a priority to increase the number of students and teachers who are proficient in the fields of science, technology, engineering and mathematics.

A recent study (Freeman, 2014) demonstrates that active learning improves student performance in science. Since student involvement is one of the most important predictors of college success (Astin, 1993), it is vital to include these methods in the university classroom. In a country where teaching is more traditional and teacher-centered, convincing instructors of the value of these new methods can have substantial impact.

The term active learning was popularized in the 1991 report to the Association for the Study of Higher Education (Bonwell & Eison, 1991). In order to learn, students must do more than just listen: they must read, write, discuss, or be engaged in solving problems. In particular, students must engage in higher-order thinking tasks such as analysis, synthesis, and evaluation. Active learning engages students in two aspects: doing things and thinking about the things they are doing.

During my presentation I will discuss current active learning techniques and how to implement them in the classroom.

Use of "ABCD Voting Cards" and Peer Instruction

Peer instruction methods consist of brief lecture-style presentations on key points of a topic followed by conceptually-challenging, multiple-choice questions. The student thinks about the question on his/her own and selects an answer. The instructor reacts based on the distribution of votes. A common practice is to ask the students to "turn to your neighbor and convince them you're right." After a discussion, the students vote again, hopefully with a majority of students choosing the correct answer. The instructor confirms the answer and carries on with the lesson.

This process forces students to think through the arguments being developed so they can explain them to their peers. Students learn better and retain knowledge longer when peer instruction is used (Crouch & Mazur, 2001).

In the United States, student polling is often done with wireless audience response technology referred to as "clickers." For the past several years, I have been developing the use of a low cost, but effective alternative to the more expensive clicker technology. "ABCD voting cards" are formed by simply printing multiple choice responses in large type on the four quadrants of a piece of paper. The paper can be folded and presented by the student to display their answer. While not providing an automatic record of individual responses, the method does show quite clearly the rough percentage of correct answers, and clearly shows the most common wrong answer. Individual student responses are visible, allowing the instructor to choose students with correct answers to explain their work to the class, or allowing for the identification of groups of students with misunderstandings.

Group Problem Solving

A similar approached can be followed with problems that require a detailed analysis of a situations (for example, a Clinical case study) or a numerical answer. In a problem solving session, students work in small groups on the solution of a problem. My classes are less than 40 students and I move around the class and help individual groups that are stuck. In larger classes, the instructor can stop the class periodically and give hints to help slower groups. After the session has ended, the instructors, or selected groups, present the correct answer to the class. The cooperation and team work that is practiced in group problem solving improves learning outcomes relative to individual work (Prince, 2004).

What Can Mathematics Education Contribute To Preparing Students For Our Future Society?

Michiel Doorman
Freudenthal Institute, Utrecht University, The Netherlands
m.doorman@uu.nl

Abstract

Mathematics education has to prepare students for society, work and further study. One of the goals of education is to support students in developing mathematical skills and understandings that can be used flexibly in new or unfamiliar problem situations. Characteristics of support that contribute to this goal appear to be the integration of open problems and rich contexts that evoke inquiry by students in textbooks, and the careful use of didactic models that link up with students' intuitive inventions. Teachers have an important role in guiding students through these open problems and in introducing these didactic models. To support teachers, such open problems can be accompanied with lesson plans and suggestions for meta-cognitive prompts.

Mathematics education has to prepare students for society, work and further study. However, international studies show that much of what is taught in school seems to be lost when you assess it not immediately after the lessons or in different contexts. An example is a question about fractions in the TIMSS 2003 Study for grade 8 students: A scoop holds 1/5 kg of flour. How many scoops are needed to fill a bag with 6 kg of flour? The international average of a full credit for this item was 38%.

Such low scores must have us reflect on what we teach and how we teach it. Obviously, citizens in current society should not be able to solve this scoop problem by heart, but you would expect that students are able to solve it with pen and paper at hand. The steps underlying the calculation are rather elementary and fundamental for proportional and algebraic reasoning in a wide range of topics in mathematics education at secondary school. Why are students lost when they don't remember the algorithm?

An approach to mathematics education that tries to provide for learning trajectories that support students in understanding and tracing concepts and skills is Realistic Mathematics Education (RME). Rather than beginning with abstractions or definitions to be applied later, this approach starts with rich contexts that ask for mathematical organization [1]. Well-chosen problems offer opportunities for students to learn to inquire and to develop informal, highly context-specific models and problem solving strategies. These informal solving procedures then function as foothold inventions for formalization, generalization and inquiry-strategies. Didactic models that link up with students' inventions are introduced in generalizing activities to promote level raising [2]. As a consequence, during these activities the model and the situations being modelled co-evolve. Modelling in this view is a process of reorganizing both activities and the situation and drives the learning process of the students [3]. The aim of this approach is that students are involved in the (re)invention of mathematics and that they are able to trace the structure and representations of mathematical concepts and skills.

In addition to this learning-oriented importance of the use of rich contexts, the relevancy of what is learned can also be highlighted. Research findings show that students experience and understand the functionality, purpose and utility of disciplinary knowledge in the workplace [4]. For this to happen however, it is important that tasks within workplace contexts also fit the goals of the curriculum. In the context of work the use of science and mathematics can emerge from the activities and tasks of the workplace [5].

Both RME and the connection to the world of work will make mathematics and science more meaningful and relevant to students. In a classroom where students inquire problem situations create mathematical inventions, students take an active role, pose questions, explore situations, find their path to solutions and communicate their reflection. Such approaches aim to promote students' curiosity, engagement and learning in-depth [6]. For this to happen, teachers need to extend their teaching repertoire. One of the challenges for professional development is to connect the learning of new teaching strategies or pedagogies with teachers' practices within the classroom. Teachers should feel the need and have the resources to adopt new ideas and to implement them in their daily practice. Classroom materials, like tasks for students, can play a crucial role in this implementation process.

Tasks have the potential to reflect innovative aims and to inspire and support teachers in implementing these aims [7]. However, whether a teacher recognizes and exploits this potential of a task and how she/he transforms it into her/his teaching is a complex process and highly depends on the adaptability of the task to his or her practice [8]. Well described lesson plans and meta-cognitive prompts appeared to be powerful tools for supporting teachers in implementing new and innovation-oriented tasks [9].
In the Netherlands RME influenced the current textbooks in primary education. The full credit score of Dutch students on the above scoop-item was 74%. This cannot fully attributed to the implementation of RME, but it strengths the feeling that this approach contributes to the quality of mathematics education.

Spatial Extreme Value Modeling Using Max-Stable Processes Approach
(Case Study: Rainfall intensity in Ngawi)

Arief Rachman Hakim [1], Sutikno [2], Dedy Dwi Prastyo [3]
[1]Department of Statistics, Institut Teknologi Sepuluh Nopember.
[2,3]Department of Statistics, Institut Teknologi Sepuluh Nopember.
Email: arief30juli@gmail.com

Abstract**—** Extreme events are short scale phenomena rarely happen, but almost unavoidable and give considerable impacts. Located in the tropical region close to the equator, Indonesia has high variability of rainfall intensities across regions. Prediction of rainfall, particularly the pattern and the characteristic of its extreme intensity, is expected to be able minimizing the loss caused the events. Extreme Value Theory (EVT) is a statistical method commonly used to study the behavior of extreme events in the univariate case. In this study, multivariate series of rainfall intensities from several locations were modeled by means of Max-Stable Processes and spatial extreme value approaches considering the spatial effect. The Generalized Extreme Value (GEV) distribution was employed in Max-Stable Processes with parameters estimation using Maximum Pairwise Likelihood Estimation (MPLE) method. The proposed method was applied to model the extreme rainfall in Ngawi region, East Java, Indonesia. The dependencies of rainfall intensities across location were indicated by the extremal coefficient plot. The best model selected based on Takeuchi Information Criterion (TIC) was used to predict return level of rainfall intensity. In this research, the prediction value of return level showed that the highest rainfall intensity increase in last two years for all stations.

Keywords: *Spatial extreme value, GEV distribution, Max-Stable processes, extreme rainfall, return level*

I. INTRODUCTION

Extreme events are short scale phenomena rarely happen, but almost unavoidable and give considerable impacts. Located in the tropical region close to the equator, Indonesia has high variability of rainfall intensities across regions. Extreme Value Theory (EVT) is a statistical method commonly used to study extreme events in the univariate case.

The EVT has two main approaches, i.e. Block Maxima (BM) and Peak Over Threshold (POT). In fact, many natural phenomena such as rainfall, temperature, and snow are related in several locations. Therefore, the observation of those event collected from several nearby locations may generate multivariate series in the sense of location. The extreme events in such cases can be modeled using spatial extreme value. There are several methods used to analyze spatial extreme value: first, the Copula approach proposed by [1], second, reference [2] had research about precipitation spatial extreme in Colorado using hierarchical Bayesian approach, and the third approach using Max Stable Processes (MSP) developed by [3]. The MSP is the extension of the multivariate extreme value theory to the infinite dimensional setting. It is used for spatial dependence modeling by transforming the marginal distribution of extreme value to the Frechet margin belongs to types of Generalized Extreme Value (GEV) distribution. The MSP has several model commonly used, for example are Smith model proposed by [4] for modeling rainfall intensity in England and Schlather model proposed by [7].

This paper will review the procedure of spatial extreme value modeling using MSP and will be applied for rainfall intensity modeling in Ngawi, East Java, Indonesia. Ngawi region is one of the main rice-producing areas in East Java, with rice production is 776,937 ton. The total harvest area is 120,929 ha where some part located in flood-prone areas [8]. Therefore, the information about extreme rainfall plays important role for early warning system to avoid the huge damage caused by the flood.

II. LITERATURE REVIEW

EVT is a statistical method used to study patterns of tail random distribution developed for univariate case. This research employed BM approach that will be described more detail as follows.

A. Block Maxima (BM)

One of methods used for identifying extreme value is BM which identifies the extreme value based on the maximum value of observations grouped by into certain period. The extreme observations collected by means of BM approach are illustrated in Figure 1.

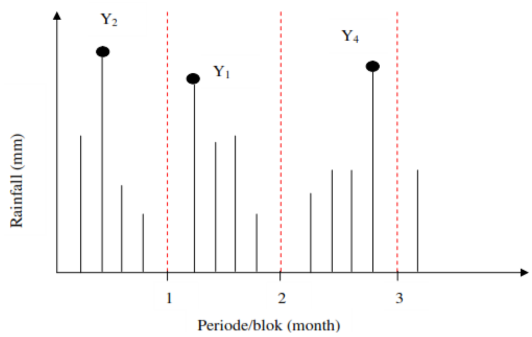

FIGURE 1. ILLUSTRATION OF BLOCK MAXIMA APPROACH

The BM approach applies the Fisher-Tippet Gnedenko (1928) theorem, i.e. the sample extreme value taken from BM will follows the GEV distribution [3]. The cumulative probability function (cdf) of GEV is formulated as follows:

$$F(y;\mu,\sigma,\xi)=\begin{cases}\exp\left\{-\left[1+\xi\left(\dfrac{y-\mu}{\sigma}\right)\right]^{-\frac{1}{\xi}}\right\},-\infty<y<\infty,\xi\neq 0,1+\xi\left(\dfrac{y-\mu}{\sigma}\right)>0\\ \exp\left\{-\exp\left(-\dfrac{y-\mu}{\sigma}\right)\right\},-\infty<y<\infty,\xi=0,\end{cases}\quad (1)$$

where $-\infty<\mu<\infty$, $\sigma>0$, and ξ are location, scale and shape parameters, respectively .

B. Spatial Extreme Modeling.

Natural phenomeda such as rainfall, temperature, and snow are related across close locations. The time series of these phenomena collected from several nearby locations can be considered as multivariate time series. Therefore, the EVT developed for univariate case is not enough. In such a case, the spatial extreme value (SEV) plays into the role. The SEV modeling requires the existence of spatial dependence of the data. The concept of spatial dependence follows Tobler first law, i.e. "*everything related to everything else, but near thing is more related than a distant thing*".

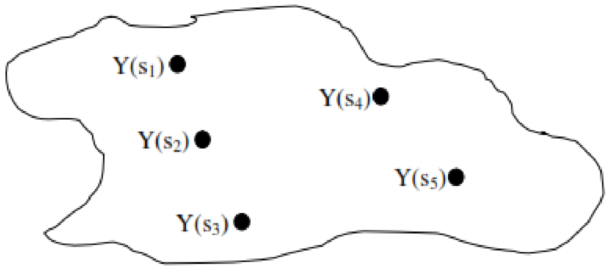

FIGURE 2. ILLUSTRATION OF SPATIAL DATA

The MSP is an approach used for the SEV modeling. The MSP increase the dimension of EVT distribution where samples were taken from the maximum value at each location [2]. It transforms the marginal distribution of extreme value into Fréchet distribution.

Let $M(s,t)$ is data of extreme events in location s and period t. The distribution of $M(s,t)$ is:

$$M(s,t) \sim GEV(\mu(s,t), \sigma(s,t), \xi(s,t)),$$

where $\mu(s,t), \sigma(s,t), \xi(s,t)$ denote location, scale, and shape parameters from GEV distribution, respectively. An arbitrary distribution function G is max stable if and only if G follows GEV distribution.

Let S be an index set and $\{Y_i(s)\}_{s\in S}, i = 1, 2, ..., n$ be n independent replications of the continuous stochastic process. Assume that there are sequences of continuous functions $a_n(s) > 0$ and $b_n(s) \in$ R such that:

$$Y(s) = \lim_{n\to\infty} \frac{\max_{i=1}^{n} Y_i(s) - b_n(s)}{a_n(s)}, \qquad n \to \infty, s \in S, \tag{1}$$

where $Y_1,..,Y_n$ are independent replications of Y. If this limit exists, then (1) is MSP [5]. If $\alpha_n(s) = n$ and $b_n(s) = 0$, then $Y(s)$ is simple MSP [3]. Assume that each component on each location has GEV distribution, do transformation into Frechet margins:

$$F(z) = \exp\left(\frac{-1}{z}\right), \qquad z > 0$$

where Z can be obtained by standardizing $\{Y(s)\}_{s\in S}$ such that:

$$\{Z(s)\}_{s\in S} = \left\{1 + \frac{\xi(s)\left(Y(s) - \mu(s)\right)}{\lambda(s)}\right\}_{+}^{1/\xi(s)} {}_{s\in S}, \tag{2}$$

where $\mu(s), \xi(s)$ and $\lambda(s) > 0$ is a continuous function. In such a case, the Z is still MSP [4].

C. Schlather Model

Reference [7] introduced one of the max-stable models so-called Schlather model. Let $Y(\cdot)$ is stationer process where $E\left[\max\{0, Y(s)\}\right] = 1$ and $\{U_j, j \geq 1\}$ is Poisson process with intensity measure $u^{-2}du$. The stationary MSP with Frechet margin unit defined in the following equation:

$$Z(s) := \max_{j\geq 1}\left(U_j Y_i(s)\right), \qquad s \in S, \tag{3}$$

where $Y_i(\cdot)$ is identically and independent replication from $Y(\cdot)$. Reference [7] proposed $Y_i(\cdot)$ as Gaussian process stationary with correlation function $\rho(h)$. The cdf of bivariate Schlather model is:

$$P_r\left[Z(y_1) \le z_1, Z(y_2) \le z_2\right] = F(z_1, z_2)$$

$$F(z_1, z_2) = \exp\left[-\frac{1}{2}\left(\frac{1}{z_1} + \frac{1}{z_2}\right)\left(1 + \sqrt{1 - 2(\rho(h)+1)\frac{z_1 z_2}{(z_1 + z_2)^2}}\right)\right], \tag{4}$$

where h is Euclidean distance between location 1 and location 2 with correlation function of $\rho\ (h)$ calculated using Cauchy model.

$$\rho(h) = c_1\left[1 + \left(\frac{h}{c_2}\right)^2\right]^{\nu}, \quad \nu > 0\ ,$$

where c_1, with $0 < c_1 \le 1$ is sill parameter and $c_2 > 0$ is range parameter.

D. Extremal Coefficient

In extreme value modeling using MSP, the measurement of extremal dependence is indispensable. Extremal coefficient describes characteristics of tail dependencies denoted as:

$$\theta(s_1 - s_2) = -z \log\left\{Z(s_1) \le z, Z(s_2) \le z\right\} \tag{5}$$

$$\theta(s_1 - s_2) = 1 + \sqrt{\frac{1 - \rho(s_1 - s_2)}{2}}$$

where $1 \le \theta(s_1 - s_2) \le 2$. If $\theta(s_1 - s_2) = 1$, then it informs full dependencies whereas if $\theta(s_1 - s_2) = 2$, then it shows independence [7].

E. Selecting the Best Model

In this work, the Takeuchi Information Criterion (TIC) will be employed to choose the best trend surface model formulated as:

$$\begin{aligned}\hat{\mu}(s) &= \beta_{\mu,0} + \beta_{\mu,1} lon(s) + \beta_{\mu,2} lat(s)\\ \hat{\sigma}(s) &= \beta_{\sigma,0} + \beta_{\sigma,1} lon(s) + \beta_{\sigma,2} lat(s)\\ \hat{\xi}(s) &= \beta_{\xi,0}\end{aligned} \tag{6}$$

The TIC is the development of Composite Likelihood Information Criterion proposed by [6]. The TIC function is given by:

$$TIC = -2\ell_p(\hat{\psi}) + 2tr\left\{H(\hat{\psi})^{-1} J(\hat{\psi})\right\} \tag{7}$$

where $H(\hat{\psi}) = -\dfrac{\partial^2 \log f(z_{ik}, z_{jk}; \hat{\psi})}{\partial\psi\partial\psi^T}$

$$J(\psi) = -\sum_{k=1}^{K} \frac{\partial \log f(z_{ik}, z_{jk}; \psi)}{\partial\psi} \frac{\partial \log f(z_{ik}, z_{jk}; \psi)}{\partial\psi^T}$$

and $i = 1,2,\ldots,m-1$, $j = 1,2,\ldots,m$, $\hat{\psi}$ is the estimator obtained from maximum pairwise likelihood.

III. EMPIRICAL RESULT

The data used in this study is cumulative rainfall intensity for each ten days in Ngawi region in period 1981-2011. First, identify the existence of heavy tail data and extreme value using the histogram as exhibited by Figure 3. The histograms show that the distribution is skew to the right with heavy tail.

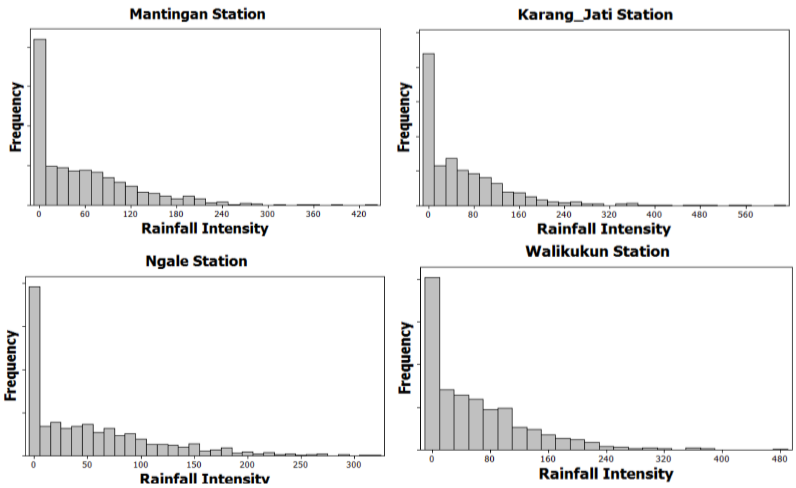

FIGURE 3. HISTROGRAM OF RAINFALL INTENSITIES FOR EACH LOCATION

Second, selecting extreme value from the original data using BM approach. Once the block period was defined, then the maximum value in each block is considered as extreme value. Figure 4 display the probability plot of extreme values in each location. I concluded that the samples of extreme rainfall with three months period (for each block) in all station in Ngawi region followed the GEV distribution.

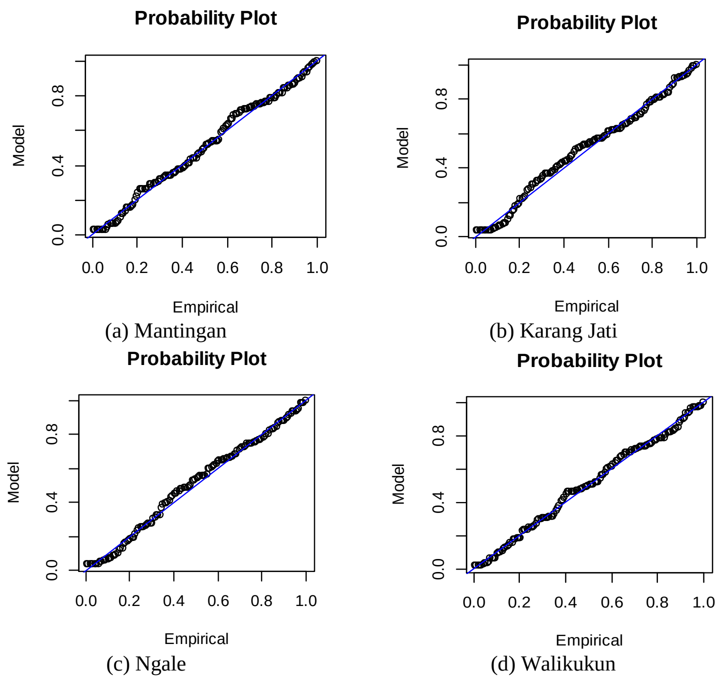

FIGURE 3. PROBABILITY PLOT OF EXTREME VALUES OBSERVATION

Third, obtain parameter sestimates $\hat{\mu}, \hat{\sigma}, \hat{\xi}$ for each location univariately using MLE continued with BFGS (Broyden, Fletcher, Goldfarb, Shanno) Quasi-Newton algorithm as optimization procedure. Table 1 summarized the parameters estimates.

TABEL 1. PARAMETERS ESTIMATES OF UNIVARIATE GEV DISTRIBUTION

Station	$\hat{\mu}$	$\hat{\sigma}$	$\hat{\xi}$
Mantingan	113.5034	79.04121	-0.15358
Karang Jati	113.2339	92.50203	-0.00933
Ngale	116.6084	80.1465	-0.27904
Walikukun	121.4399	81.73469	-0.11292

Fourth, transforming the extreme rainfall data obtained from BM approach into Frechet distribution using Z transformation as follows:

$$Z\left(s_i\right)=\left(1+\xi\,\frac{y-\mu}{\sigma}\right)^{1/\xi}$$

where y is extreme value sample, s_i shows the location and $\hat{\mu}, \hat{\sigma}, \hat{\xi}$ are GEV parameters obtained in step 3.

Fifth, to obtain parameter estimates (Smooth, Range, Nugget) for spatial dependence modeling using Schlachter model. In the beginning, counting spatial dependence with an extremal coefficient for each pair of location, see Table 2. Equation for extremal coefficient with Schlather model is:

$$\theta(s_i-s_j)=-z\log P\left\{Z(s_i)\le z, Z(s_j)\le z\right\}$$

$$\theta\left(s_i-s_j\right)=1+\sqrt{\frac{1-\rho\left(s_i-s_j\right)}{2}}$$

If $1\le\theta\left(s_1-s_2\right)\le 2$ then the data have spatial dependencies. Parameter estimates of spatial dependence using Schlather model is summarized in Table 3.

TABEL 2. EXTREMAL COEFFICIENT

Euclidean distance	Extremal coefficient
0.46874	1.310179
0.22158	1.295339
0.073479	1.316569
0.247165	1.294821
0.400665	1.310192
0.154637	1.236751

TABEL 3. PARAMETERS ESTIMATES OF SPATIAL DEPENDENCE

correlation function	nugget	range	smooth
Cauchy	0.219356	2.218379	10.03399

Sixth, obtain parameters estimates for GEV distribution using Maximum Pairwise Likelihood Estimation (MPLE) method followed by using BFGS Quasi-Newton. The GEV spatial model is given by:

$$GEV\left(\hat{\mu}(s), \hat{\sigma}(s), \hat{\xi}(s)\right)$$

where GEV parameter obtained from trend surface model combination, i.e.:

$$\hat{\mu}(s) = \hat{\beta}_{\mu,0} + \hat{\beta}_{\mu,1} lon(s) + \hat{\beta}_{\mu,2} lat(s)$$
$$\hat{\sigma}(s) = \hat{\beta}_{\sigma,0} + \hat{\beta}_{\sigma,1} lon(s) + \hat{\beta}_{\sigma,2} lat(s)$$
$$\hat{\xi}(s) = \hat{\beta}_{\xi,0}$$

The best model was selected based on TIC. The smallest TIC value is 2357.718 from the combination of trend surface models:

$$\hat{\mu}(s) = \hat{\beta}_{\mu,0} + \hat{\beta}_{\mu,2} lat(s) = 0.964676 + 0.001744\, lat(s)$$
$$\hat{\sigma}(s) = \hat{\beta}_{\sigma,0} + \hat{\beta}_{\sigma,2} lat(s) = 0.972590 + 0.004346\, lat(s)$$
$$\hat{\xi}(s) = \hat{\beta}_{\xi,0} = 1.079$$

The parameters of GEV spatial Schlather model in each station were reported in Table 4.

TABEL 4. PARAMETERS ESTIMATES OF GEV SPATIAL

Station	$\hat{\mu}$	$\hat{\sigma}$	$\hat{\xi}$
Mantingan	0.951842253	1.45569397	1.079
Karang Jati	0.951679014	1.45769009	1.079
Ngale	0.95176325	1.45663662	1.079
Walikukun	0.951774586	1.45596516	1.079

TABEL 5. PREDICTION OF RETURN LEVEL

Station	2 year (2013)	3 year (2014)
Mantingan	273.8945	304.6252
Karang Jati	298.2324	337.5429
Ngale	285.3738	320.5566
Walikukun	276.8673	318.2706

The results from last step were used to compute to predict return level of rainfall extreme for each station in Ngawi region. The period used in return level calculation is two years and three years ahead. The general equation for return level calculation is:

$$z_p(s) = \hat{\mu}(s) - \frac{\hat{\sigma}(s)}{\hat{\xi}(s)}\left(1 - \left[-\ln\left(1 - \frac{1}{T}\right)\right]^{-\xi(s)}\right).$$

where $T = 2\text{ year} \times 4\,(\text{number of block}) = 8$. The predictions of return level for two and three years were summarized in Table 5. In 2013, the predicted cumulative heaviest rainfall for ten days in Karang Jati Station is 298.2324 mm. The return level increased in 2014 become 337.5429 mm. As happened in Karang Jati, the prediction of return level for all station increased significantly from 2013 to 2014.

IV. CONCLUSION AND SUGGESTION

The empirical results indicated that extreme rainfall data in Ngawi followed univariate GEV distribution. The shape parameter estimates were always negative for each location in univariate analysis whereas they were positive constant in multivariate analysis, i.e. GEV spatial. In this study, the prediction value of return level showed that the highest rainfall intensity increase in last two years. Further research can consider more locations in order to obtain more meaningful results.

Bivariate Binary Probit Model Approach for Birth Attendance and Labor Participation in West Papua

Ayu Tri Septadianti[1*], Vita Ratnasari[1], Ismaini Zain[1]
[1]Department of Statistics, Faculty of Mathematics and Natural Science, Institut Teknologi Sepuluh Nopember, Surabaya 60111, Indonesia
tri.septadianti@gmail.com

Abstract— The indicators used to determine the quality of the health services and the rate of public health in a region is including the Maternal Mortality Rate (MMR). One ways to reduce the maternal mortality rate in Indonesia is assisted the birth by trained health personnel and deliver at health care facilities. Extent of delivery assistance by health professionals nationwide in 2014 decreased by 2,2% from the year 2013 with the highest order is D.I. Yogyakarta and the lowest is West Papua. Selection of non-medical birth assistance is mostly done by women who do not work. That is because women who don't work haven't better access about health. This study aims to applying binary bivariate probit model to determine the factors that affect the birth attendance and labor participation. Source of data used in this research is the data of the National Socio Economic Survey (SUSENAS) in West Papua Province year 2014. Parameter estimation method used bivariate probit model is the Maximum Likelihood Estimation (MLE) with Newton Raphson iteration. The best model selection criterion based on the AIC (Akaike Information Criterion) generate information that mother's, area status, and age of mother have a significant effect on birth attendance and labor participation.

Keywords: *Birth Attendance, Labor Participation, Bivariate Binary Probit, MLE, AIC*

I. INTRODUCTION

One of the Millenium Development Goals (MDGs) goals is to improve maternal health, with the target of reducing maternal mortality by three-quarters between 1990 - 2015, as well as indicators for monitoring that the maternal mortality rate, the proportion of aid deliveries by skilled health personnel, and the contraceptive prevalence rate. Results based on data from Indonesia Health Profile 2014 show that birth attendance by health professionals in 2014 decreased 2,2% from 2013. The lowest coverage of births attended by trained health personnel is the province of West Papua was 44,73%. Selection of non-medical birth assistance is mostly done by women who do not work. That is because women who don't work have not access about health and health facilities [1]. Moreover, mothers who do not work and do not have health insurance tend to choose non-medical birth attendant with individual characteristics in rural areas.

Probit regression model is the model which uses to analyze dependent response variable in the form of qualitative with predictor variables in the form of quantitative or qualitative. Bivariate probit model uses two dichotomous variables as the response variable. Bivariate binary probit model has been carried out in many researches. Hamori and Chen (2010) used bivariate probit model to analyze of different between male and female formal employment in Urban China. Wahyudi (2014) used binary bivariate probit model that focuses on rural and urban poverty modelling with the poverty line approach in Bengkulu Province. Based on previous descriptions, this study will be applying binary bivariate probit model to determine the factors that affect the birth attendance and labor participation.

II. STATISTICAL METHODOLOGY

The statistical method is a procedure used in collecting, analysis presenting and interpretation of data. In this section, presented the framework of statistical method for estimating birth attendance probabilities of working mothers and do not work.

A. Bivariate Binary Probit Regression Model

Bivariate binary probit regression model is a model that consist of two response variables in the form of binary categorical data whereas the predictor variables in the form of discrete variables and continuous. This model has two qualitative response variables Y_1 and Y_2 are assumed from latent variable Y_1^* and Y_2^* with each of the response variables has two categories [2]. Therefore, bivariate binary probit model is represented as follows [3]:

$$y_1^* = \boldsymbol{\beta_1 X} + \varepsilon_1 \tag{1}$$

$$y_2^* = \boldsymbol{\beta_2 X} + \varepsilon_2 \tag{2}$$

where,

y_1^*, y_2^* : latent (not directly observed) dependent variables
β : vector of estimable parameters
X : vector of explanatory variables
$\varepsilon_1, \varepsilon_2$: disturbance terms assumed to be normally distributed with zero mean and variance of 1, and correlation of ρ.

The values for $y_1^*$and y_2^* are unobservable and related to the following binary dependent variables, on the basis of the following conditions:

$Y_1 = 1$, if $y_1^* > 0$; $Y_1 = 0$, if $y_1^* \leq 0$

and

$Y_2 = 1$, if $y_2^* > 0$; $Y_2 = 0$, if $y_2^* \leq 0$

B. Maximum Likelihood Estimation

The parameters of the bivariate binary probit model can be estimated by maximum likelihood estimation method. Due to the estimation parameters generated by bivariate binary probit model was not close formed, the solution is using a numerical method by Newton Raphson iteration [2]. The log-likelihood function is given by:

$$L(\beta_1, \beta_2, \rho) = \prod_{i=1}^{n} P(Y_{11i} = y_{11i}, Y_{10i} = y_{10i}, Y_{01i} = y_{01i}) \tag{3}$$

C. Simultaneous Test of Bivariate Binary Probit Model

The hypotheses used in the simultaneous test as follows:

H_0 : $\beta_{11} = \beta_{12} = \cdots = \beta_{1k}$ and $\beta_{21} = \beta_{22} = \cdots = \beta_{2k}$

H_1 : At least one $\beta_{ij} \neq 0$ for $i = 1,2$ and $j = 1,2, \ldots, k$

The test statistic for testing the parameters of a bivariate probit model simultaneously represented as follows [3]:

$$G^2 = 2\sum_{i=1}^{n}\left[y_{11i} \ln\left(\frac{\hat{p}_{2i} - \hat{p}_{01i}}{\hat{p}_{2i}^* - \hat{p}_{01i}^*}\right) + y_{10i} \ln\left(\frac{\hat{p}_{1i} - \hat{p}_{2i} + \hat{p}_{01i}}{\hat{p}_{1i}^* - \hat{p}_{2i}^* + \hat{p}_{01i}^*}\right) + y_{10i} \ln\left(\frac{\hat{p}_{01i}}{\hat{p}_{01i}^*}\right) + y_{00i} \ln\left(\frac{1 - \hat{p}_{1i} - \hat{p}_{01i}}{1 - \hat{p}_{1i}^* - \hat{p}_{01i}^*}\right)\right] \tag{4}$$

H_0 is rejected at significance level α if $G^2 > \chi^2_{df,\alpha}$.

D. Partial Test of Bivariate Binary Probit Model

The aims of this test is to see the effect of each predictor variable toward response variables Y_1 and Y_2. The hypothesis is as follows:

$H_0 : \beta_{kl} = 0$

$H_1 : \beta_{kl} \neq 0$ with $k = 1,2$ and $l = 1,2,\ldots,m$

The test statistic for testing the parameters of a bivariate probit model partially represented as follows [2],

$$G^2 = 2\sum_{i=1}^{n}\left[y_{11i} \ln\left(\frac{\hat{p}_{11i}}{\hat{p}_{11i}^{**}}\right) + y_{10i} \ln\left(\frac{\hat{p}_{10i}}{\hat{p}_{10i}^{**}}\right) + y_{10i} \ln\left(\frac{\hat{p}_{01i}}{\hat{p}_{01i}^{**}}\right) + y_{00i} \ln\left(\frac{\hat{p}_{00i}}{\hat{p}_{00i}^{**}}\right)\right] \quad (5)$$

At a significance level α, rejected H_0 if $G^2 > \chi^2_{1,\alpha}$.

E. Akaike Information Criterion (AIC)

The best model selection criterion for bivariate binary probit model based on the Akaike Information Criterion (AIC). AIC is a model of the goodness of fit criteria parameters estimated based on the maximum likelihood method [4]. Thus, the AIC value can be obtained as follows:

$$AIC = \frac{-2\ln L(M_p) + 2q}{n} \quad (6)$$

III. EMPIRICAL RESULT

In this section will be reviewed modelling results of bivariate binary probit model. Afterwards, the full model will be selection for get the best model using AIC method.

A. Descriptive Statistical

Source of data used in this research is the data of the National Socio Economic Survey (SUSENAS) in West Papua Province Year 2014 with the observation units of households is the children aged 0-5 years old by 1357 households. The data used as the response variable is last birth attendants and mothers work participation. The predictor variables used the mother's last education, area status, age of mother, and age of first marriage mother.

Based on Table 1, it can be known that the selection of non-medical birth attendant in the West Papua province is still relatively high, reaching 31.17%. Selection of non-medical birth attendance is mostly done by women who do not work.

TABEL 1. DESCRIPTIVE TABLE OF RESPONSE VARIABLE

		Labor Participation		**Count**
		Non-labor	Labor	
Birth Attendance	Non-medical	233 (17,17%)	190 (14,00%)	423 (31,17%)
	Medical	568 (41,86%)	366 (26,97%)	934 (68,83%)
Count		801 (59,03%)	556 (40,97%)	1357

In bivariate probit regression modeling, between the response variable must be dependent. To determine dependency between the variable birth attendants and labor participation of mothers it is necessary to do a test. Dependency test used is Chi-Square test [5]. The results of processing using

SPSS20 programs, Chi-Square values obtained by 3,954 higher than $\chi^1_{(0,05;1)}$= 3,84. This means that there is a relationship between birth attendants with the labor participation of mother.

B. Bivariate Binary Probit Modelling

Full modeling results for all variables with bivariate binary probit model represented as follows:

$$\hat{y}_1^* = -0{,}7264 + 0{,}451D_{1.1} + 1{,}1498D_{1.2} + 0{,}6942D_2 + 0{,}0072X_3 + 0{,}0114X_4$$

$$\hat{y}_2^* = 0{,}3218 - 0{,}384D_{1.1} + 0{,}1136D_{1.2} - 0{,}2315D_2 - 0{,}0166X_3 + 0{,}0085X_4$$

Furthermore, the created models be tested simultaneously and partially to determine the effect of predictor variables on the response variable. Simultaneous testing conducted to determine whether the predictor variables have a significant effect or not for the response variable. Based on the results of the processing of binary bivariate probit model using StataSE12 program obtained *Wald Chi-Square* (G^2) value 282,96 or *p-value* less than α= 0,05, so can be concluded H_0 rejected. This means that at least one significant predictor variables on the response variable.

On the other hand, to determine which variables that influence the response variable is necessary to do partial test. Partial testing conducted to determine the effect of each predictor or no significant effect on the response variable. Based on the test results of the bivariate probit model partially, in Table 2 show that the variables that significantly influence birth attendants variable is the mother's education (X_1) and the status area (X_2) (*p-value* <α = 0.05). In addition, Table 2 also represented that the variables mother education at elementary school or equivalent junior high school ($D_{1.1}$), the status area (X_2), and age of mother (X_3) significantly affects the labor participation of mothers (*p-value* <α = 0 , 05).

TABEL 2. *P-VALUE* RESULT OF THE BIVARIATE BINARY PROBIT MODEL (FULL MODEL)

Predictor Variable		Birth Attendance (Y_1)		Labor Participation (Y_2)	
		Std. Err.	*p-value*	*Std. Err.*	*p-value*
Mother's Education (X_1)	Elementary School or Junior High School or equivalent ($D_{1.1}$)	0,1010	0,000	0,1003	0,000
	Senior High School or College or equivalent ($D_{1.2}$)	0,1205	0,000	0,1110	0,3066
Area Status (X_2)	Urban (D_2)	0,0947	0,000	0,0805	0,004
Age of Mother (X_3)	-	0,0055	0,194	0,0055	0,002
First Marriage Age of Mother (X_4)	-	0,0100	0,257	0,0095	0,365

C. The Best Model Selection

In the complete modelling, it is known that all the predictor variables have not been significant to $\hat{y}_1^*$ or $\hat{y}_2^*$. Furthermore, it needs to do the best model selection using AIC method. By combining all possible models or as much as 2^p-1 with *p* number of predictor variables and the values of AIC are provided in Table 3.

TABEL 3. AIC VALUE BIVARIATE BINARY PROBIT MODEL

No.	Model	AIC	No.	Model	AIC
1.	X_1, X_2, X_3, X_4	3222,211	9.	X_2, X_3	3373,809
2.	X_1, X_2, X_3	**3220,437**	10.	X_2, X_4	3381,377
3.	X_1, X_2, X_4	3228,814	11.	X_3, X_4	3474,924
4.	X_1, X_3, X_4	3280,959	12.	X_1	3293,097
5.	X_2, X_3, X_4	3355,259	13.	X_2	3391,539
6.	X_1, X_2	3329,250	14.	X_3	3503,691
7.	X_1, X_3	3279,622	15.	X_4	3501,408
8.	X_1, X_4	3290,019			

Based on Table 3, it can be seen that the selection results of the best model with the smallest AIC value is a model which involves X1, X2 and X3. So the best bivariate binary probit model formed is as follows:

$$\hat{y}_1^* = -0{,}5984 + 0{,}4499D_{1.1} + 1{,}1787D_{1.2} + 0{,}6969D_2 + 0{,}0103X_3$$

$$\hat{y}_2^* = 0{,}416 - 0{,}384D_{1.1} + 0{,}1375D_{1.2} - 0{,}2297D_2 - 0{,}0142X_3$$

From the binary bivariate probit best models, then tested parameters simultaneously and partially. Based on the results of StataSE12 program obtained that either by testing simultaneously or partially, the variables X1, X2 and X3 significant effect on the response variable.

IV. CONCLUSION

This paper showed that there is a dependency between the response variable birth attendants and labor participation based on the results of Chi-Square Test. Modelling using a binary probit bivariate produce the best model for AIC value of 3220,437 with significant variable is the mother's education variable (X_1), the status area (X_2), and the age of mother (X_3).

Parameter Estimation and Hypothesis Testing on Bivariate Generalized Poisson Regression

Dian Kusuma Wardani[1], Purhadi[2], Wahyu Wibowo[3]
[1]Student of Magister Statistics, Institute of Technology Sepuluh Nopember, Surabaya, Indonesia
[2,3]Department of Statistics, Institute of Technology Sepuluh Nopember, Surabaya, Indonesia
dian.wardani14@mhs.statistika.its.ac.id/dian.wardani10@gmail.com

Abstract— Poisson regression is regression method used to analyze response variable which is discrete. Equality of mean and variance (equidispersion) are the assumption that must be fulfilled in this model. If assumption is violated, the conclusion would be not valid. Wrong assumption occurs if variance greater than mean and is often called (overdispersion). But if variance less than mean it is called (underdispersion). There is no data used with excessive zero value on the response variable, therefore this research uses Bivariate Generalized Poisson Regression. Parameter estimation of Bivariate Generalized Poisson Regression is done by using Maximum Likelihood Estimation (MLE).

Keywords: *overdispersi, underdispersi, bivariate generalized poisson regression, MLE*

I. INTRODUCTION

Regression analysis is statistical method which is often used in science. The aim of analysis is modeling the relationship between two variables, which consist of predictor variable and response variable. In general, regression analysis is used in response variable which is continuous, but sometime response variable is discrete. Type of response variable is discrete which count data is non-negative that declare a lot of events in interval time, space or void volume. Data from an event would follow the Poisson distribution if such events are rare in a large sample[1]. This modeling is called Poisson Regression. There is assumption that must be met, mean and variance of response variable should be the same [6]. If assumption is violated, the conclusion would be not valid. Assuming violation occurs if variance is greater than mean is called overdispersion and if variance is less than mean is called underdispersion. Bivariate Poisson regression is used in data that have two response variables in data count with a high correlation.

II. LITERATURE

A. Bivariate Poisson Regression

Random variables Y_1, Y_2 is jointly bivariate Poisson distribution and according to [5] joint probability function :

$$f(y_1, y_2) = \begin{cases} e^{-(\mu_1+\mu_2+\mu_0)} \displaystyle\sum_{k=0}^{\min(y_1,y_2)} \frac{\mu_1^{\,y_1-k}\mu_2^{\,y_2-k}\mu_0^{\,k}}{(y_1-k)!(y_2-k)!k!} & ,(y_1,y_2)=0,1,2,\ldots \\ 0 & ,(y_1,y_2) \text{ yang lain} \end{cases} \quad (1)$$

Bivariate poisson regression model can be written

$$(Y_{1i}, Y_{2i}) \sim PB(\mu_{1i}, \mu_{2i}, \mu_0)$$
$$\mu_{ji} + \mu_0 = e^{x_i^T \beta_j};\ j = 1,2 \quad (2)$$

Estimation method is used on Bivariate Poisson Regression is Maximum Likelihood Estimation (MLE) [4]. The method for calculating statistic test in parameter test is using Maximum Likelihood Ratio Test (MLRT) :

$$D(\hat{\beta}) = -2\ln\left(\frac{L(\hat{\omega})}{L(\hat{\Omega})}\right) = 2\left(\ln L(\hat{\Omega}) - \ln L(\hat{\omega})\right) \tag{3}$$

where

$L(\hat{\Omega})$: Maximum Likelihood for complete model with predictor variable

$L(\hat{\omega})$: Maximum Likelihood for simple model without predictor variable

B. Generalized Poisson Regression

Generalized Poisson Regression is used to modeling overdispersion or underdispersion [2]. According to [3], Generalized Poisson Distribution has probability function:

$$f(y_i, \mu_i, \alpha) = \left(\frac{\mu_i}{1+\alpha\mu_i}\right)^{y_i} \frac{(1+\alpha y_i)^{y_i-1}}{y!} \exp\left(\frac{-\mu_i(1+\alpha y_i)}{1+\alpha\mu_i}\right) \tag{4}$$

$$\mu_i = \mu_i(x_i) = \exp(\mathbf{x_i}\boldsymbol{\beta})$$

Generalized Poisson Regression model have same form as Poisson Regression model:

$$\mu_i = \exp(\mathbf{x_i^T}\boldsymbol{\beta}) = \exp(\beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + ... + \beta_k x_{ki}) \tag{5}$$

Estimation method is used on Generalized Poisson Regression is Maximum Likelihood Estimation (MLE). Method to compute statistic test on parameter test is using Maximum Likelihood Ratio Test (MLRT):

$$D(\hat{\beta}) = -2\ln\left(\frac{L(\hat{\omega})}{L(\hat{\Omega})}\right) = 2\left(\ln L(\hat{\Omega}) - \ln L(\hat{\omega})\right) \tag{6}$$

where

$L(\hat{\Omega})$: Maximum Likelihood for complete model with predictor variables

$L(\hat{\omega})$: Maximum Likelihood for simple model without predictor variables

C. Bivariate Generalized Poisson Regression

According to [7] for example N_1, N_2, N_3 are random variable and independent so Generalized Poisson distribution $Y_1 = N_1 + N_3$ and $Y_2 = N_2 + N_3$ Consul dan Shoukri (1985) in Vernic (1997) explained that $X \sim GDP(\mu, \alpha)$ then the probability function of Bivariate Generalized Poisson :

$$f(y_{1i}, y_{2i}) = \left\{ \begin{array}{l} \mu_{1i}\mu_{2i}\mu_0 \exp\{-(\mu_{1i}+\mu_{2i}+\mu_0) - y_{1i}\alpha_1 - y_{2i}\alpha_2\} \\ \sum\limits_{k=0}^{\min(y_1,y_2)} \frac{1}{(y_{1i}-k)!(y_{2i}-k)!k!}(\mu_{1i}+(y_{1i}-k)\alpha_1)^{y_1-k-1})(\mu_{2i}+(y_{2i}-k)\alpha_2)^{y_2-k-1})(\mu_0+k\alpha_0)^{k-1}) \\ \exp\{k(\alpha_1+\alpha_2-\alpha_0)\} \end{array} \right\}$$

Model of Bivariate Generalized Poisson Regression is

$$\mu_{ji} = \exp(\mathbf{x_i^T}\boldsymbol{\beta_j}) = \exp(\beta_{j0} + \beta_{j1} x_{1i} + \beta_{j2} x_{2i} + ... + \beta_{jk} x_{ki})$$

Parameter estimation of Bivariate Generalized Poisson Regression is done by using Maximum Likelihood Estimation (MLE). The method for calculating statistic test is using Maximum Likelihood Ratio Test (MLRT):

$$D(\hat{\beta}) = -2\ln\left(\frac{L(\hat{\omega})}{L(\hat{\Omega})}\right) = 2\left(\ln L(\hat{\Omega}) - \ln L(\hat{\omega})\right) \tag{9}$$

where

$L(\hat{\Omega})$: Maximum Likelihood for complete model with predictor variables

$L(\hat{\omega})$: Maximum Likelihood for simple model without predictor variables

III. METHOD

Steps to get parameter estimator Bivariate Generalized Poisson Regression model is (1) Forming the likelihood function of Bivariate Generalized Poisson Regression model; (2) Forming function ln likelihood of Bivariate Generalized Poisson Regression model; (3) Transforming ln likelihood function; (4) Looking first partial derivative of ln likelihood function; (5) Looking for second partial derivatives of ln likelihood function; (6) Getting parameter estimator with Newton Raphson iteration; (7) Hypotheses test simultaneous is using MLTR and partial test.

IV. RESULT AND DISCUSSION

Parameter estimation method Bivariate Generalized Poisson Regression is a Maximum Likelihood Estimation (MLE) with probability function:

$$f\left(y_{1i}, y_{2i}\right) = \left\{ \begin{array}{l} \mu_0 \mu_{1i} \mu_{2i} \exp\left\{-\left(\mu_0 + \mu_{1i} + \mu_{2i}\right) - y_{1i}\alpha_1 - y_{2i}\alpha_2\right\} \sum\limits_{k=0}^{\min(y_1, y_2)} \dfrac{(\mu_{1i} + (y_{1i}-k)\alpha_1)^{y_{1i}-k-1}}{(y_{1i}-k)!} \times \\ \dfrac{(\mu_{2i} + (y_{2i}-k)\alpha_2)^{y_{2i}-k-1}}{(y_{2i}-k)!} \times \dfrac{(\mu_0 + k\alpha_0)^{k-1}}{k!} \left(\exp k\left(\alpha_1 + \alpha_2 - \alpha_0\right)\right) \end{array} \right\}$$

the function ln likelihood of Bivariate Generalized Poisson:

$$Q = \ln L\left(\mu_0 \boldsymbol{\beta}_1 \boldsymbol{\beta}_2 \alpha_1 \alpha_2\right) = \left\{ \begin{array}{l} \sum\limits_{i=1}^{n} \ln \mu_0 + \sum\limits_{i=1}^{n} \ln\left(e^{\mathbf{x}_i^T \boldsymbol{\beta}_1} - \mu_0\right) + \sum\limits_{i=1}^{n} \ln\left(e^{\mathbf{x}_i^T \boldsymbol{\beta}_2} - \mu_0\right) - n\mu_0 + \\ \sum\limits_{i=1}^{n}\left(e^{\mathbf{x}_i^T \boldsymbol{\beta}_1} - \mu_0\right) + \sum\limits_{i=1}^{n}\left(e^{\mathbf{x}_i^T \boldsymbol{\beta}_2} - \mu_0\right) - \sum\limits_{i=1}^{n} y_{1i}\alpha_1 - \sum\limits_{i=1}^{n} y_{2i}\alpha_2 + \sum\limits_{i=1}^{n} \ln W_i \end{array} \right\}$$

the first derivative of $\ln L(\mu_0 \boldsymbol{\beta}_1^T \boldsymbol{\beta}_2^T \alpha_1 \alpha_2)$ to μ_0 is

$$\frac{\partial Q}{\partial \mu_0} = \frac{-n}{\mu_0} - n - 2 + \sum_{i=1}^{n} \sum_{k=0}^{\min(y_1 y_2)} \left\{ \frac{-\left(y_{1i}-k-1\right)}{\left(\left(e^{\mathbf{x}_i^T \boldsymbol{\beta}_1} - \mu_0\right) + \left(y_{1i}-k\right)\alpha_1\right)} + \left(\frac{-\left(y_{2i}-k-1\right)}{\left(\left(e^{\mathbf{x}_i^T \boldsymbol{\beta}_2} - \mu_0\right) + \left(y_{2i}-k\right)\alpha_2\right)} + \frac{k-1}{\left(\mu_0 + k\alpha_0\right)} \right) \right\} \tag{10}$$

the first derivative of $\ln L(\mu_0 \boldsymbol{\beta}_1^T \boldsymbol{\beta}_2^T \alpha_1 \alpha_2)$ to $\boldsymbol{\beta}_1$ is

$$\frac{\partial Q}{\partial \boldsymbol{\beta}_1} = \left\{ \begin{array}{l} \sum\limits_{i=1}^{n} \dfrac{1}{e^{\mathbf{x}_i^T \boldsymbol{\beta}_1}} \left(\exp\left(\mathbf{x}_i^T \boldsymbol{\beta}_1\right) \mathbf{x}_i\right) + \sum\limits_{i=1}^{n}\left(\exp\left(\mathbf{x}_i^T \boldsymbol{\beta}_1\right) \mathbf{x}_i\right) + \\ \sum\limits_{i=1}^{n} \sum\limits_{k=0}^{\min(y_1 y_2)} \left(y_{1i}-k-1\right)\left(\left(e^{\mathbf{x}_i^T \boldsymbol{\beta}_1} - \mu_0\right) + \left(y_{1i}-k\right)\alpha_1\right)^{y_{1i}-k-1} \left(e^{\mathbf{x}_i^T \boldsymbol{\beta}_1}\right) \mathbf{x}_i \end{array} \right\} \tag{11}$$

the first derivative of $\ln L(\mu_0 \boldsymbol{\beta}_1^T \boldsymbol{\beta}_2^T \alpha_1 \alpha_2)$ to $\boldsymbol{\beta}_2$ is

$$\frac{\partial Q}{\partial \boldsymbol{\beta}_2} = \left\{ \begin{array}{l} \sum\limits_{i=1}^{n} \dfrac{1}{e^{\mathbf{x}_i^T \boldsymbol{\beta}_2}} \left(\exp\left(\mathbf{x}_i^T \boldsymbol{\beta}_2\right) \mathbf{x}_i\right) + \left(\exp\left(\mathbf{x}_i^T \boldsymbol{\beta}_2\right) \mathbf{x}_i\right) + \sum\limits_{i=1}^{n} \sum\limits_{k=0}^{\min(y_1 y_2)} \left(y_{2i}-k-1\right) \\ \left(\left(e^{\mathbf{x}_i^T \boldsymbol{\beta}_2} - \mu_0\right) + \left(y_{2i}-k\right)\alpha_2\right)^{y_{2i}-k-1} \left(e^{\mathbf{x}_i^T \boldsymbol{\beta}_2}\right) \mathbf{x}_i \end{array} \right\} \tag{12}$$

the first derivative of $\ln L(\mu_0 \boldsymbol{\beta}_1^T \boldsymbol{\beta}_2^T \alpha_1 \alpha_2)$ to α_1 is

$$\frac{\partial Q}{\partial \alpha_1} = -\sum_{i=1}^{n} y_{1i} + \sum_{i=1}^{n} \sum_{k=0}^{\min(y_1 y_2)} \left(\frac{\left(y_{1i}-k-1\right)\left(y_{1i}-k\right)}{\left(\left(e^{\mathbf{x}_i^T \boldsymbol{\beta}_1} - \mu_0\right) + \left(y_{1i}-k\right)\alpha_1\right)^{y_{1i}-k}} + 1 \right) \tag{13}$$

the first derivative of $\ln L(\mu_0 \boldsymbol{\beta}_1^T \boldsymbol{\beta}_2^T \alpha_1 \alpha_2)$ to α_2 is

$$\frac{\partial Q}{\partial \alpha_2} = -\sum_{i=1}^{n} y_{2i} + \sum_{i=1}^{n} \sum_{k=0}^{\min(y_1 y_2)} \left(y_{2i}-k\right)\left(y_{2i}-k-1\right)\left(\left(e^{\mathbf{x}_i^T \boldsymbol{\beta}_2} - \mu_0\right) + \left(y_{2i}-k\right)\alpha_2\right)^{y_{2i}-k-1} \quad (14)$$

the first derivative does not close form so that to solve the equation is using Newton Rahpson iteration with equation (15) as follow

$$\hat{\boldsymbol{\theta}}_{(m+1)} = \hat{\boldsymbol{\theta}}_{(m)} - \mathbf{H}^{-1}\left(\hat{\boldsymbol{\theta}}_{(m)}\right)\mathbf{g}\left(\hat{\boldsymbol{\theta}}_{(m)}\right) \quad (15)$$

$$\boldsymbol{\theta} = \left(\mu_0, \boldsymbol{\beta}_1^T, \boldsymbol{\beta}_2^T, \alpha_1, \alpha_2\right)^T$$

$$\mathbf{g}^T\left(\boldsymbol{\theta}_{(m)}\right)_{(k+1)} = \left(\frac{\partial \ln L(\boldsymbol{\theta})}{\partial \mu_0}, \frac{\partial \ln L(\boldsymbol{\theta})}{\partial \boldsymbol{\beta}_1}, \frac{\partial \ln L(\boldsymbol{\theta})}{\partial \boldsymbol{\beta}_2}, \frac{\partial \ln L(\boldsymbol{\theta})}{\partial \alpha_1}, \frac{\partial \ln L(\boldsymbol{\theta})}{\partial \alpha_2}\right)_{\boldsymbol{\theta}=\boldsymbol{\theta}_{(m)}} \quad (16)$$

$$\boldsymbol{H}(\boldsymbol{\theta}_{(m)})_{(k+1)(k+1)} = \begin{bmatrix} \frac{\partial^2 \ln L(\boldsymbol{\theta})}{\partial \mu_0^2} & \frac{\partial^2 \ln L(\boldsymbol{\theta})}{\partial \mu_0 \partial \boldsymbol{\beta}_1^T} & \frac{\partial^2 \ln L(\boldsymbol{\theta})}{\partial \mu_0 \partial \boldsymbol{\beta}_2^T} & \frac{\partial^2 \ln L(\boldsymbol{\theta})}{\partial \mu_0 \partial \alpha_1} & \frac{\partial^2 \ln L(\boldsymbol{\theta})}{\partial \mu_0 \partial \alpha_2} \\ & \frac{\partial^2 \ln L(\boldsymbol{\theta})}{\partial \boldsymbol{\beta}_1^T \partial \boldsymbol{\beta}_1} & \frac{\partial^2 \ln L(\boldsymbol{\theta})}{\partial \boldsymbol{\beta}_1^T \partial \boldsymbol{\beta}_2} & \frac{\partial^2 \ln L(\boldsymbol{\theta})}{\partial \boldsymbol{\beta}_1^T \partial \alpha_1} & \frac{\partial^2 \ln L(\boldsymbol{\theta})}{\partial \boldsymbol{\beta}_1^T \partial \alpha_2} \\ & & \frac{\partial^2 \ln L(\boldsymbol{\theta})}{\partial \boldsymbol{\beta}_2^T \partial \boldsymbol{\beta}_2} & \frac{\partial^2 \ln L(\boldsymbol{\theta})}{\partial \boldsymbol{\beta}_2^T \partial \alpha_1} & \frac{\partial^2 \ln L(\boldsymbol{\theta})}{\partial \boldsymbol{\beta}_2^T \partial \alpha_2} \\ & & & \frac{\partial^2 \ln L(\boldsymbol{\theta})}{\partial \alpha_1 \partial \alpha_1^T} & \frac{\partial^2 \ln L(\boldsymbol{\theta})}{\partial \alpha_1 \partial \alpha_2} \\ & \textit{Simetris} & & & \frac{\partial^2 \ln L(\boldsymbol{\theta})}{\partial \alpha_2 \partial \alpha_2^T} \end{bmatrix} \quad (17)$$

Hessian matrix is matrix that contain second derivative of function $\ln L(Q)$ to the parameter $\left(\mu_0, \boldsymbol{\beta}_1^T, \boldsymbol{\beta}_2^T, \alpha_1, \alpha_2\right)$

Parameter estimation steps with Newton-Raphson iteration is

1. Determining the initial value of parameter
2. Forming vector $\mathbf{g}(\boldsymbol{\theta})$ by substituting equation (10), (11), (12), (13) and (14) into the equation (15)
3. Hessian matrix forming by substitute the resulting equation of second derivative into (17).
4. Inserting values into $\hat{\boldsymbol{\theta}}_{(0)}$ vector elements $\mathbf{g}$ and matrix $\mathbf{H}$
5. Starting from $m = 0$ iterating at the equation (15) . Value $\hat{\boldsymbol{\theta}}_{(m)}$ is a collection of parameter estimator which convergent the current iteration m.
6. If have not gotten parameter estimation are convergent, then proceeded to step 5 to $m = m+1$ iteration. Iteration will stop if the value of $\left\|\hat{\boldsymbol{\theta}}_{(m+1)} - \hat{\boldsymbol{\theta}}_{(m)}\right\| \le \varepsilon$.

Hypothesis test is done in two parts that is

i. Hypothesis testing simultaneous is using MLTR with hypotheses

Parameter $\boldsymbol{\beta}$

$H_0 : \beta_{j1} = \beta_{j2} = ... = \beta_{jk} = 0; j = 1, 2$

H_1 : at least one $\beta_{jk} \ne 0;\ j = 1, 2$ with $l = 1, 2, ..., k$

Parameter α

$H_0 : \alpha_1 = \alpha_2 = 0;$

H_1 : at least one $\alpha_j \neq 0;\ j = 1, 2$

Statistical test :

$$D(\hat{\beta}) = -2\ln\left(\frac{L(\hat{\omega})}{L(\hat{\Omega})}\right) = 2\left(\ln L(\hat{\Omega}) - \ln L(\hat{\omega})\right)$$

$L(\hat{\Omega})$:Maximum Likelihood for complete model with predictor variables and $L(\hat{\omega})$: Maximum Likelihood for simple model without predictor variables. The rejection region H_0 if $D(\beta) > \chi^2_{(\alpha,v)}$

ii. Hypothesis testing partial is using Z-test with hypothesis

Parameter β

$H_0 : \beta_{jl} = 0$

$H_1 : \beta_{jl} \neq 0$ with $j = 1, 2$ and $l = 1, 2, ..., k$

Statistical test :

$$Z_{cal} = \frac{\hat{\beta}_{jl}}{SE(\hat{\beta}_{jl})}$$

The rejection region H_0 if $|Z_{cal}| > Z_{(\alpha,v)}$

Parameter α

$H_0 : \alpha_j = 0$

$H_1 : \alpha_j \neq 0$ with $j = 1, 2$

Statistical test :

$$Z_{cal} = \frac{\hat{\alpha}_j}{SE(\hat{\alpha}_j)}$$

The rejection region H_0 if $|Z_{cal}| > Z_{(\alpha,v)}$

RESULT

Parameter estimation model on Bivariate Generalized Poisson Regression is using Maximum Likelihood (ML). The results obtained from parameter estimation does not close form that needs to be done by Newton Raphson iteration. On hypothesis test is using Maximum Likelihood Ratio Test (MLTR) by comparing the value of the likelihood under H_0 and likelihood under population. Hypothesis test is done in two parts simultaneous and partial.

Scour Analysis at Seawall in Salurang, Sangihe Islands Regency, North Sulawesi

Eunike Irene Kumaseh[1], Suntoyo[2], Muh.Zikra[3]
[1, 2,3] Department of Ocean Engineering, Faculty of Marine Technology, Institut Teknologi Sepuluh Nopember, Surabaya - Indonesia
eunikekumaseh@gmx.com

Abstract. Sangihe Islands Regency is one of the outermost regions of the unitary Republic of Indonesia. The area is dominated by coastal areas. Thus, many coastal structures protection built to guard the coastal areas from the threat of big waves. Local scour is the erosion of the basis on a particular part of a building coast. If it occurs continously, it could lead to instability of the structure or structural failure. The research takes a case study on scouring at Seawall in Salurang, Sangihe Islands Regency, North Sulawesi. This study aims to determine dominant factor of scouring and predict the maximum scour depth and scour length at seawall by using Van Rijn method (2013) which is one method of numerical calculation. The method is expected to provide the right solution for handling a scouring at coastal structures in this area. The right method to predict maximum scour depth in Salurang, Sangihe Islands regency is the scour method near the tip of wall-type or rubble-mound-type structure due to waves (plus weak currents <0.3 m/s). Scour due to combination of waves and currents. The maximum scour depth value is 0.36 m and the scour length is 3.6 m. The local government can protect the coastal structure by providing stone mound at the toe based on the calculation of the maximum scour depth.

Keywords: *Maximum scour depth, seawall, Van Rijn method, Sangihe Islands Regency*

I. INTRODUCTION

Sangihe Islands Regency is an integral part of the capital city of North Sulawesi Tahuna. Located approximately 142 Nautical Miles from the capital of North Sulawesi, Manado, located between 2 ° 4'13 "- 4 ° 44 '22" North Latitude and 125 ° 9' 28 "- 125 ° 56 '57" East, located between the Sulawesi islands and Mindanao (Republic of the Philippines), so the Sangihe Islands Regency can be categorized as "Frontier". The total area of Sangihe Islands Regency amounted to 736.98 km2 [1]. As a coastal region, this region, many built of coastal protection structures to prevent the influence of big waves. Seawall was built in Salurang village in 2003 with a length of 471.2 m, a width of 1 m and a height of 4 m. However, the scouring which caused by damage to some parts of the structure will occur in the local seawall few years later.

Sumer, et al. (2001) has conducted research on scouring the various types of coastal structures and scour depth development model with physical and numerical modeling [5]. El-bisy (2006) has studied on the seawalls and predict scour using neural network models (ANNs) [3]. This study will predict the maximum scour depth on the seawall in Kampung Salurang using Van Rijn method (2013) [9]. Thus, is expected to provide the right solution for protection against scouring. And, the proper handling of coastal protection.

Scour will occur anywhere the hydrodynamic shear stresses on the bottom are high enough to initiate sediment transport. Clear water scour occurs when bottom shear stresses are high only in a localized portion of the bed; outside the local region sediment is not moving. This occurs mostly in uniform, steady flow situations. In live bed scour, bottom shear stresses over the entire bed exceed the level for incipient motion with locally higher shear stresses where greater scour occurs. An equilibrium is reached when the volume of sediment being removed from the scour hole is exactly equal to sediment being deposited in its place. Understanding the physical processes involved in scour is difficult because the shear stresses responsible for scour are developed by waves, currents, or combined waves and currents, that usually are heavily influenced by the presence of a coastal structure. Because of the distinct influence coastal structures exert on the hydrodynamics, structural aspects such as geometry, location, and physical characteristics (roughness, permeability, etc.) impact the scour process. Therefore, modifying some physical characteristic of a structure may reduce scour potential. [2]

II. METHODS

A. Refraction Analysis

To get a value of wave height at structure, it is necessary to analyze the refraction, by some calculations below.

$L_0 = 1.56T^2$ (m)	[wave length at deep water]	(1)
$C_0 = L_0/T$ (m/s)	[celerity at deep water]	(2)
$L = d/(\frac{d}{L})$ (m)	[wave length]	(3)
$C = L/T$ (m)	[celerity]	(4)
$\sin a = (\frac{C}{C_0}) \sin a_0$	[a = incident wave angle]	(5)
$K_r = (\cos a_0 \,/\, \cos a)^{0.5}$	[refraction coefficient]	(6)
$K_s = (n_0 \times L_0/n \times L)^{0.5}$	[shoaling coefficient]	(7)
$H = K_s \times K_r \times H_0$ (m)	[wave height] [10]	(8)

B. Van Rijn Method

To predict maximum scour depth, used the formulas below.

#1 Scour near toe of wall-type or rubble-mound-type structures due to waves

- Scour's formula for Wall-type structure
  a. SPM, 1984 $d_{s,max} = SF.h_{toe}$ (9)
  b. Fowler, 1992
  $\frac{h_{toe}}{L_0} < 0{,}06 \rightarrow d_{s,max} = SF\left(11{,}4\left(\frac{h_0}{L_0}\right) + 0{,}54\right).h_{s,off}$ (10)
  $\frac{h_{toe}}{L_0} > 0{,}06 \rightarrow d_{s,max} = SF.h_{s,off}$ (11)
  c. SATO, 1968
  $h_0 < 9 \rightarrow d_{s,max} = SF(-0{,}2.h_0 + 1{,}9)$ (12)
  $h_0 > 9 \rightarrow d_{s,max} = 0{,}1.SF.h_0$ (13)
  d. Yokoyama, 2002
  $\frac{H_s}{h_{toe}} > 0 \rightarrow d_{s,max} = SF\left(2.\frac{H_s}{h_{toe}} - 0{,}5\right).h_{toe}$ (14)
  $\frac{H_s}{h_{toe}} < 0 \rightarrow d_{s,max} = 0{,}1.SF.h_{toe}$ (15)
  e. Xie, 1981
  $\frac{h_{toe}}{L_w} < 0{,}15 \rightarrow d_{s,max} = SF\left(-64.\frac{h_{toe}}{L_w} + 1{,}2\right)h_{toe}$ (16)
  $\frac{H_s}{h_{toe}} > 0{,}15 \rightarrow d_{s,max} = 0{,}25.SF.h_{toe}$ (17)
- Scour's formula for Rubble-mound-type structure

Scour length is assumed to be 0,7 × scour depth of wall – type structures.

#2 Scour near tip of wall-type and rubble-mound type structures due to waves (plus weak current < 0.3 m/s)

- Scour's formula for Wall-type structure

Sumer, 1997

Maximum value of: $KC\ Number < 10 \rightarrow d_{s,max} = 0{,}05.SF.\ KC\ Number.B$ (18)

$KC\ Number > 10 \rightarrow d_{s,max} = 0{,}5.SF.B;$ (19)

and $d_{s,max} = 0{,}2.h_{toe}$ (20)

- Scour's formula for Rubble-mound-type structure

a. Sumer, 1997
Maximum value between

$$T_p\left(\frac{9{,}81.h_{toe}}{h_0}\right)^{0,5} < 15 \rightarrow d_{s,max} = 0{,}03.SF.\left(T_p\left(\frac{9{,}81.h_{toe}}{h_0}\right)^{0,5}\right) \quad (21)$$

$$T_p\left(\frac{9{,}81.h_{toe}}{h_0}\right)^{0,5} > 15 \rightarrow d_{s,max} = 0{,}5.SF.h_{toe} \quad (22)$$

And, $d_{s,max} = 0{,}15.h_{toe}$ (23)

b. Field Data Japan, USA

$$h_0 < 15 \rightarrow d_{s,max} = SF.(-0{,}033.h_0 + 0{,}7).h_0 \quad (24)$$

$$h_0 > 15 \rightarrow d_{s,max} = 3.SF \quad (25)$$

$$d_{s,max} = 0{,}15.h_{toe} \quad (26)$$

#3 Scour near tip of wall-type and rubble-mound type structures due to relatively strong current (> 0.3 m/s) plus waves

$$h_0 < 14 \rightarrow d_{s,max} = SF \times (-0.25 \times h_0 + 4) \times h_0 \quad (27)$$

$$h_0 > 14 \rightarrow d_{s,max} = SF \times 7 \quad (28)$$

Generally, for scour length = 10 *x* Scour depth (29)

Where h_0 = depth at toe exclude scour, $d_{s,max}$ = maximum scour depth, SF = safety factor, T_p = peak wave period, h_{toe} = local wave height at toe, $KC\ Number$ = Keulegan-Carpenter Number, B = width of structure, L_w = wave length, H_s = significant wave height, $h_{s,off}$ = offshore significant wave height. And the mathematical formula for computing correlation coefficient = r is:

$$r = \frac{n\sum xy - (\sum x)(\sum y)}{\sqrt{n(\sum x^2) - (\sum x)^2}\sqrt{n(\sum y^2) - (\sum y)^2}}, \quad (30)$$

where n is the number of pairs of data. The value of r is that $-1 \leq r \leq 1$. The $+$ and – signs are used for positive linear correlations and negative linear correlations, respectively. The coefficient of determination, r^2 or R^2, is useful because it gives the proportion of the variance (fluctuation) of one variable that is predictable from the other variable. The coefficient of determination is the ratio of the explained variation to the total variation. The coefficient of determination is such that $0 \leq r^2 \leq 1$, and denotes the strength of the linear association between x and y. The coefficient of determination represents the percent of the data that is closest to the line of best fit.

III. RESULTS AND DISCUSSION

The results of measurement and prediction for the maximum scour depth were shown in Tables 1-4. The comparison was given in Figure 1-3.

- Results of Measurement

TABEL 1. SCOUR DEPTH BY MEASUREMENT

h_0	Scour depth maximum = $d_{s,max}$ (m)	Scour Length (m)
1	0.6	6
1.79	0.64	6.4
1.95	0.37	3.7

- Results of Prediction

a. Scour near toe of wall-type or rubble mound-type structure due to waves

TABEL 2. MAXIMUM SCOUR DEPTH DUE TO WAVES

h_0	Scour depth maximum = $d_{s,max}$ (m)	Scour Length (m)
1	1.05	10.5
1.79	1.27	12.7
1.95	1.31	13.1

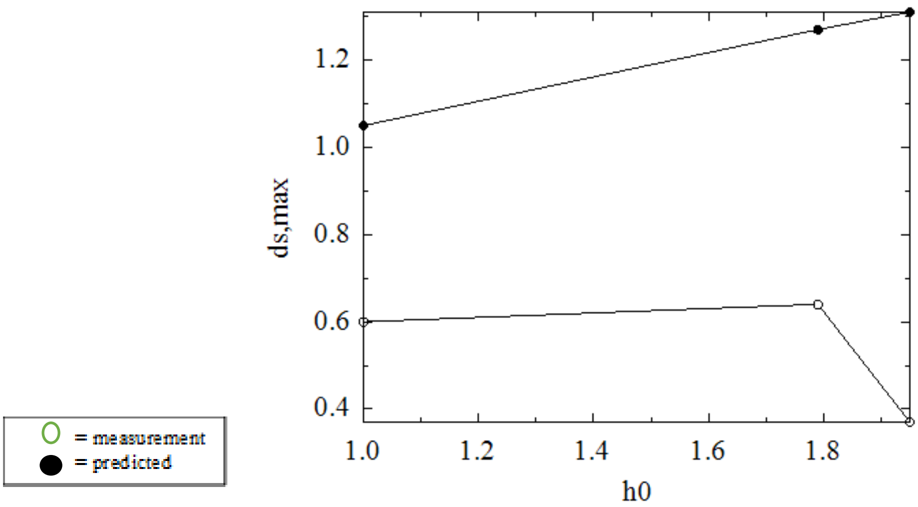

FIGURE 1. COMPARISON BETWEEN PREDICTION AND MEASUREMENT DUE TO WAVES

Based on the comparison between measurement and prediction have a coefficient correlation = r = 0.4. And $r^2 = 0.16$. It means that the prediction not accurately because the value of r^2 closest to 0.

b. Scour near tip of wall-type or rubble-mound-type structure due to waves (plus weak currents <0.3 m/s)

TABEL 3. MAXIMUM SCOUR DEPTH DUE TO WAVES PLUS WEAK CURRENT

h_0	Scour depth maximum = $d_{s,max}$ (m)	Scour Length (m)
1	0.3	3
1.79	0.36	3.6
1.95	0.35	3.5

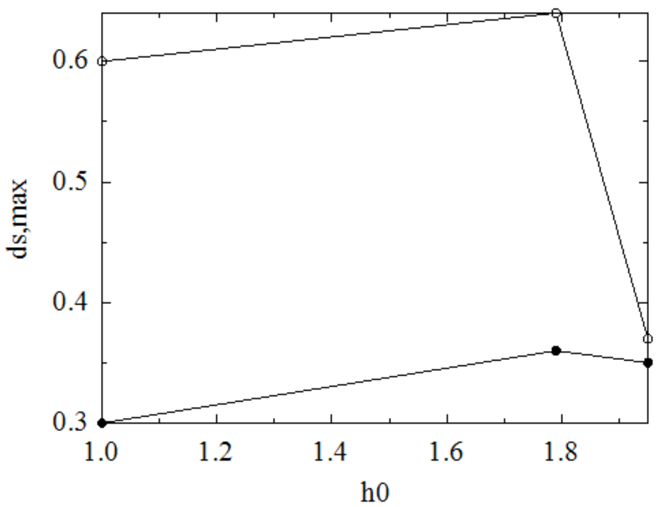

FIGURE 2. COMPARISON BETWEEN PREDICTION AND MEASUREMENT DUE TO WAVES PLUS WEAK CURRENT

Based on the comparison between prediction and measurement have a coefficient correlation r = 0.9. And $r^2 = 0.81$. It means that the prediction very accurately because the value of r^2 closest to 1.

c. Scour near tip of wall-type or rubble-mound-type structure due to relatively strong current (>0.3 m/s) plus waves.

TABEL 4. MAXIMUM SCOUR DEPTH DUE TO WAVES PLUS STRONG CURRENT

h_0	Scour depth maximum = $d_{s,max}$ (m)	Scour Length (m)
1	3.75	37.5
1.79	6.36	63.6
1.95	6.85	68.5

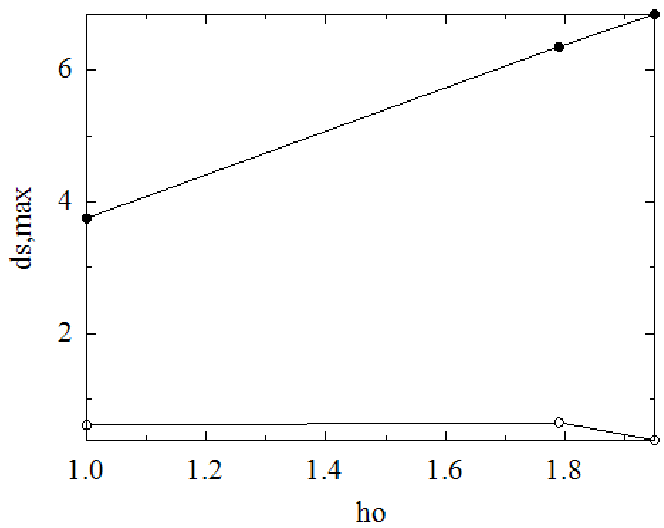

FIGURE 3. COMPARISON BETWEEN PREDICTED AND MEASUREMENT DUE TO WAVES PLUS STRONG CURRENT

Based on the comparison between prediction and measurement have a coefficient correlation r = 0.4. And $r^2 = 0.16$. It means that the prediction not accurately because the value of r^2 closest to 0.

From the results of comparison above, it can be seen that r^2 closest to 1 was on scour method calculation near the tip of wall-type or rubble-mound-type structure due to waves (plus weak currents <0.3 m/s). Scour due to combination of waves and currents. Thus, it can be said that the right method to be used in the calculation of scouring in the Salurang village, Sangihe Islands Regency is a scour method calculation near the tip of wall-type or rubble-mound-type structure due to waves (plus weak currents <0.3 m / s) with a maximum scour depth is 0.36 m and scour length is 3.6 m.

IV. CONCLUSION

The right method to predict maximum scour depth in Salurang, Sangihe Islands regency is the scour method near the tip of wall-type or rubble-mound-type structure due to waves (plus weak currents <0.3 m/s). Scour due to combination of waves and currents. The maximum scour depth value is 0.36 m and the scour length is 3.6 m. The local government can protect the coastal structure by providing stone mound at the toe based on the calculation of the maximum scour depth.

ACKNOWLEDGEMENT

Thank you for Mr. Suntoyo and Mr. Zikra for guide the first author, for support from my classmate, Laboratory of post graduate Faculty of Marine Technology, and for everybody who completing this study. Hopefully this article can be useful.

Longitudinal Tobit Regression

Modelling Stroke Patients With Trauma/Injury HeadTrauma

***Abstract*—** Stroke is a major health problem for modern society. In the case of patients with stroke, a stroke patients often experience trauma / head injury due to falls in the bathroom, fell on the stairs or after waking. One way to determine the severity of head injuries in stroke patients is used of medical records Glasgow Coma Scale (GCS). But the scoring system at GCS alone sometimes has problems, such as pain medications under investigation and response variables measured on the visual analog, some patients will be reported "no pain" after a certain time. They could not say a lesser degree or higher from a sense of "no pain". To solve it, scoring at GCS will be given sensor at a certain value. Medical records on the severity of the trauma / injury done repeatedly over time. Time is very important and in the measurement of an event expected to be recorded properly. One approach that can be performed on longitudinal data which has a sensor point is to approach tobit longitudinal regression method. The response variable is the score on the Glasgow Coma Scale. The predictor variables having a significant effect is blood pressure (X_1), body temperature (X_2) and pulse (X_3).

Keywords: *Stroke, Longitudinal Tobit, Glasgow Coma Scale*

I. INTRODUCTION

Stroke is a major health problem for our modern society. Today, sroke increasingly becoming a serious malash facing almost all over the world. That is because the sudden stroke can result in death, physical disability and mental well childbearing age and the elderly [1]

In the case of patients with stroke, a stroke patients often experience trauma / head injury due to falls in the bathroom, fell on the stairs or after waking. Trauma / head injury in stroke patients require ongoing medical record to ensure further medical treatment. With minimal facilities, the scoring system becomes very necessary to assess the state of consciousness and prognosis of the patients experienced injuries. One way to determine the severity of head injuries in stroke patients is the use of medical records Glasgow Coma Scale (GCS). GCS itself based on the patient's response to eye opening, verbal function and various motoric functions of the various stimulus [2]. GCS scoring system on his own sometimes have problems, such as pain medications under investigation and response variables measured on the visual analog, some patients will be reported "no pain" after a certain time. They can not tell the lower levels of "no pain". To overcome this problem then scoring on the Glasgow Coma Scale will be given sensor on one particular value.

In some studies, the response variables of the specific research has the highest limit from time to time. The actual level of the highest scoring test takers can not be measured properly and this phenomenon is called the effect of the highest limit. Effect occurs when the upper limit in a study, test scale relative ease so that everyone receives a proportion of the maximum or near the maximum value can not be determined [3]. To handle data censored at the upper limit tobit developed and applied approach.

The approach taken is to use longitudinal regression tobit where medical records GCS were observed repeatedly during the 14 days when the patient is treated, will be modeled factors that affect the severity of head trauma patients. It is hoped that by knowing the factors that influence can be seen the severity of injury / trauma and can be given treatment in the healing of patients to the fullest

II. METHOD

A. *Tobit Regression*

Model tobit (Truncated Regression) or so-called censored regression is a regression analysis that is used to describe the relationship between the dependent variable and the independent variable where the dependent variable scale mix. Tobit The term was first proposed by James Tobin in 1958 were used to analyze the expenditures of the households in the United States to buy the cars [4]. Modeling tobit formed by first assuming the existence of a relationship linear between Y^* with variabel X expressed by :

$$y_i^* = x_i^T \beta + \varepsilon_i \tag{1}$$

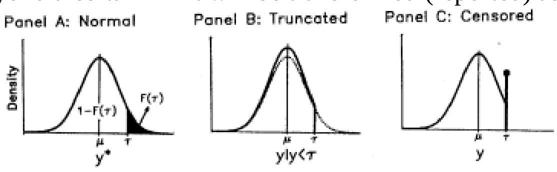
With y^* contains a latent variable that represents the value censored. When y^* with ceiling effects $y_i^* \geq \tau$, so the variabel respon (Y) cencored was definition likes:

$$y_i = \begin{cases} y_i^* = x_i^T \beta + \varepsilon_i & jika \ y_i < \tau \\ \tau & jika \ y_i \geq \tau \end{cases} \tag{2}$$

Where τ is threshold where $i = 1, 2, ..., n$ and n is the number of observations.

B. The Concept of Data Cencored

Sensor occurs when the observations were made on variables for the entire sample, but there are some observations on the response variable that has limited information. When a censored response variable, the value of observation beyond a certain limit will be transformed (reported) as a single value [5]



Long [8] explain that if you use all the data to the regression model to the data censored, will generate parameter values over estimate the intercept. Whereas if eliminating the observation that value is not known, will produce the coefficient parameters underestimate the slope and the intercept overestimate. And truncated cause correlations between predictor variables with residual, resulting in inconsistent estimates.

C. Longitudinal Data Analysis

Longitudinal data analysis is a study that refers to the observation that the measurement is repeated from time to time [6]. Such studies have appeared in various fields. In the field of medical study was conducted to measure the rehabilitation of stroke patients were observed at various times and circumstances. This study is very effective for studying the effects of time on certain characteristics.The main objective of the analysis was to determine the response of the middle value, expressed as a function of time. In general, longitudinal data set is written as follows:

$$\left(y_{ij}, t_{ij}\right) \quad i = 1, 2, ..., m; \quad j = 1, 2, ..., n_i \tag{3}$$

Where:

y_{ij} : measurement to j (from n_i measurement) to object i (from m object)

t_{ij} : time measurement y_{ij}

Longitudinal data is data obtained through a repeated observations carried out against a number of objects. Such data have appeared in various fields such as medicine, agriculture, economics. Most longitudinal studies designed to determine the value of the middle of the response as a function of time, with due regard to the role of the explanatory variables.

D. Longitudinal Tobit Analysis

For longitudinal data, tobit models can be defined in the same manner as in the classic longitudinal analysis, the underlying model y^* is a linear mixed models

$$y_{ij}^* \mid b_i = x_{ij}{}' \beta + z_{ij}{}' b_i + e_{ij} : N(0, \sigma^2) \tag{4}$$

Where's i refers to the subject i and j .

Estimation of the parameters of the model tobit approximated using Gaussian quadrature. An advantage of the Gaussian quadrature estimate is that the accuracy can be assessed by comparing with a different number of points quadrature. When quadrature obtained by assuming a normal, posterior density estimates of latent variables tend to work well for a continuing response and in large numbers.

E. Glasgow Coma Scale

Glasgow Coma Scale is a standardized scoring system to assess the neurological status of patients with head injury / awareness. GCS accurate value is used to direct treatment and for the prediction of patient outcome. GCS was first introduced in 1970 in Glasgow by Jennet and Teasdale. Rate Glasgow Coma Scale (GCS) is:

Table 1: Glasgow Coma Scale Score

No	**Item assessed**	**Skor**
1.	Opened the eyes responses	4 = Spontaneous 3 = Against the verbal stimulus 2 = Against the painful stimulus 1 = No respon
2	Verbal Responses	5 = Oriented on time 4 = Confused 3 = Words irregular 2 = Unclear voice 1 = No voices
3	Motoric responses	6 = obey ordered 5 = Shows the location of pain 4 = Avoid 3 = Abnormal flexion 2 = Abnormal extency 1 = No Respon

F. Stroke

Stroke is a major health problem for today's modern society. The sudden stroke can result in death, physical and mental disability both in their productive age and old age. Stroke is a disorder of neurological dysfunction acute caused by circulatory disorders, and sudden in onset (within seconds) or at least rapidly (within hours) with symptoms and signs according to the focal area of the brain that is impaired. In the case of patients with stroke, a stroke patients often experience trauma / head injury due to falls in the bathroom, fell on the stairs or after waking. Trauma / head injury in stroke patients require ongoing medical records to ensure further medical treatment.

III. RESULTS

A. Data Source

The data used in this study were taken from a longitudinal study of the rehabilitation of stroke patients in which the calculation includes the Glasgow Coma Scale, blood pressure, temperature and pulse rate in patients with stroke. Total sample consisted of 80 patients with stroke in Haji Surabaya hospital with the duration of treatment for 14 days.

B. Research Variable

Response variable (Y) used in this research is the score on the Glasgow Coma Scale (GCS) for the calculation of trauma / injury head stroke patients. GCS' sensor point based on the degree of severity of head injury. GCS' scores can be seen in table 2

Table 2 Respon Variable (Y)

Glasgow Coma Scale	**Score**
Mild Of Head Trauma/Injury	13-15
Middle Of Head Trauma/Injury	9-12
Hard Of Head Trauma/Injury	3-8

The predictor variables were included in this study are blood pressure, body temperature and pulse.

C. Results

In the tabel 3 presented descriptive statistic from the lower margin of Glasgow Coma Scale's score.

Table 3. Ceiling Proportion

GCS	Ceiling Proportion													
	D1	D2	D3	D4	D5	D6	D7	D8	D9	D10	D11	D12	D13	D14
Mild (13-15)	4%	2%	7%	8%	12%	2%	3%	7%	23%	44%	14%	36%	15%	35%
MIddle (9-12)	7%	4%	7%	5%	12%	4%	3%	14%	23%	5%	21%	27%	12%	25%
Hard (3-8)	0%	0%	3%	3%	5%	4%	5%	8%	3%	2%	12%	12%	2%	23%

Table 3 displays the descriptive statistics (means and standard deviation) and different ceiling proportions across fourteen times. Therefore, different type have substantially different ceiling proportions. The highest score for stroke patiens in the mild group is 44% in day 10 and in the middle group is 27% in day 11. Because different proportions of Glasgow coma scale scores may have different magnitudes of influences on parameter estimates. The sample mean and covariance matrix of the generated data with ceiling threshold = 13 were presented in table 4.

Table 4 The Sammple mean and cov with CT=13

	Ceiling Threshold = 13			
	(Y)	X_1	X_2	X_3
Mean vector	7.8	9.2	10.3	12.2
Covariance Matrix				
(Y)	4.3	5.6	5.6	4.7
X_1	4.2	4.8	5.3	3.5
X_2	4.5	3.7	4.8	2.8
X_3	4.3	5.1	3.6	3.0

Abstract**—**In recent years, remuneration had a warm conversation among researchers. Remuneration has a goal to improve the performance of the state apparatus to become more efficient, effective, and more prosperous. The aim of this paper is to estimate multilevel structural equation modeling with latent variables to evaluating the effectiveness of present remuneration for administrative staff in ITS Surabaya. Multilevel Structural Equation Modeling is a method that combines Structural Equation Modeling and multilevel analysis simultaneously. The analysis is performed using secondary data from the research "Development and Indicator Specification of Present Remuneration For Administrative staff in ITS Surabaya". The hypothesis measure of the effectiveness of remuneration is a latent variable obtained by performance with the demographic factor like gender and latest education background. The opinion was expressed on a five ordered likert scale. The effectiveness of remuneration used three indicators. The results based on 100 administrative staff from 10 subject area indicate that performance is causally influence to the effectiveness of remuneration in individual level. While in activity level latest education background and gender are casually influence.

Keywords: *multilevel analysis, structural equation modeling, remuneration*

I. INTRODUCTION

In recent years, remuneration had a warm conversation among researchers. Remuneration is an attempt to change the payroll system and a calculation based on the difficult of responsibility, risk, scope of work and others, its can say the remuneration received some sort of reward for performance of a state apparatus in accordance with the positions and functions held. Remuneration has a goal to improve the performance of the state apparatus to become more efficient, effective, and more prosperous. The new remuneration started in 2013 under PP No. 88. While ITS will be start the implementation of remuneration in 2014. To explain the perception of the remuneration policy that has been applied in an organization requires research involving variable role in the level of group or activity unit other than the individual level.

The next problem is remuneration cannot be measured directly, so we need a capable method of solving these problems. Multilevel Structural Equation Modeling (MSEM) is a method that combines Structural Equation Modeling (SEM) and multilevel analysis simultaneously [1]. MSEM allows researchers to simultaneously test and estimate the relationship between exogenous and endogenous with many indicators in the clustered data where the lower levels will nest in the unit with the higher levels.

The analysis is performed using a two-level structural equation model with latent variables, where the effectiveness of remuneration in individual are considered as first level units and effectiveness of remuneration in subject area as second level units. The choice of a two-level analysis is justified to explain the nested data structure and to analyze in a single statistical model variables measured at different levels. In this case, individual levels are clustered in subject area and if they share unobserved factors it may expect related values of the response variables. As a result, observations may not be independent and identically distributed. In this case, a two level analysis allows to get accurate parameters and standard errors estimates and to explain the variability associated with each level. The analysis is limited to only two levels because we consider that the main effects on effectiveness of remuneration in individual level are exercised by the units to the next higher level.

II. MULTILEVEL STRUCTURAL EQUATION MODELING

Multilevel Structural Equation Modeling (MSEM) is an advanced SEM technique developed for multilevel research. MSEM can be applied to a wide range of applications that involve multilevel multivariate data, including multilevel factor analysis and multilevel path analysis models [1]. This approach formulates decomposition models for the individual (within) level and cluster (between) level. When the dependent variable are not normally distributed, for example ordered polytomous, ordinal categorical, binary or censored variables, multilevel model can be estimated with limited-information weighted least square [2].

A. Model Specification

Let y_{pij} be the *p*–th observed dependent variable, $p = 1,2,..., P$, for individual i, $i = 1,2,..., N_j$, in cluster $j = 1,2,..., C$, where N_j is the number of individuals in cluster j. Let x_{wqij} be the *q*–th observed individual predictor variable, $q = 1,2,..., Q_1$, for individual i in cluster j and x_{bqj} be the *q*–th observed cluster level predictor variable, $q = 1,2,..., Q_2$, observed for cluster j. To construct the latent variable model by defining an underlying normally distributed latent variable y^*_{pij}. If the *p*–th variable is normally distributed then $y^*_{pij} = y_{pij}$. If the *p*–th variable is categorical, for a set of parameters τ_{pk} [2].

$$y_{pij} = k \Leftrightarrow \tau_{pk} < y^*_{pij} < \tau_{pk+1} \tag{1}$$

The two-level model is constructed as [4].

$$y^*_{pij} = y_{wpij} + y_{bpj} \tag{2}$$

where y_{wpij} and y_{bpj} are normally distributed independent latent variables. Two separate latent variable models are defined for y_{wpij} and y_{bpj}. Suppose that η_{wmij} are normally distributed latent variables defined on the individual level, $m = 1,2,..., M_1$ and are normally distributed latent variables defined on the cluster level, $m = 1,2,..., M_2$. The vector variables defined as $y_{wij} = (y_{w1ij}, y_{w2ij},..., y_{wPij})$ and similarly y_{bj}, η_{wij}, η_{bj}, x_{wij}, and x_{bj}. The structural model on the within level is given by (3-4) and on the between level is given by (5-6).

$$y_{wij} = \Lambda_w \eta_{wij} + \varepsilon_{wij} \tag{3}$$

$$\eta_{wij} = B_w \eta_{wij} + \Gamma_w x_{wij} + \xi_{wij} \tag{4}$$

$$y_{bj} = \nu_b + \Lambda_b \eta_{bj} + \varepsilon_{bj} \tag{5}$$

$$\eta_{bj} = \alpha_b + B_b \eta_{bj} + \Gamma_b x_{bj} + \xi_{bj} \tag{6}$$

where the vector and matrix parameters Λ_w, Γ_w, B_w, Λ_b, Γ_b, B_b, ν_b, α_b as well as the thresholds parameters are to be estimated. The residual matrices ε_{wij}, ξ_{wij}, ε_{bj} and ξ_{bj} are independent and normally distributed with zero mean. Their respective covariances are denoted by Θ_w, Ψ_w, Θ_b and Ψ_b. In order to obtain identification, the variance of is fixed at 1 if the *p*–th variable is categorical [3].

B. Sample Estimates

The data is expressed as saturated model. It contains no latent constructs η_{wij} or η_{bj}, and full covariance matrices are fitted for the within and the between level variables. The thresholds of categorical variables have the same construction as in (1) and the underlying latent is defined as in the structural model specified in (2).

$$y_{pij} = k \Leftrightarrow t_{pk} < y^*_{pij} < t_{pk+1} \tag{7}$$

The structural part of the model is defined by

$$y_{wij} = \Pi_w x_{wij} + \in_{wij} \tag{8}$$

$$y_{bj} = \mu_b + \Pi_b x_{bj} + \in_{bj} \tag{9}$$

The residual vectors $\in_{wij}$ and $\in_{bj}$ are assumed normally distributed with 0 means and covariance matrices Σ_w and Σ_b, respectively. For identification purposes, if the *p*–th variable is categorical, the variance of $\in_{wpij}$ is fixed at 1 and the mean parameter μ_{pb} is fixed at 0.

The parameters in (8) and (9) are estimated in two stages. The first stage is for the estimation of univariate parameters: the between means μ_{bp}, the thresholds t_{pk}, the coefficients Π_{wpq} and Π_{bpq}, and the diagonal elements of the residual covariance matrix, Σ_{wpp} and Σ_{bpp}. At the second stage, the covariances of residuals, that is, the off-diagonal elements of Σ_w and Σ_b are estimated with bivariate likelihood methods, given the univariate estimates [3].

C. Structural Model Estimation

In the third stage of the two-level weighted least square estimation, the structural or restricted model parameters are estimated. Notice that the structural model (1-6) can be viewed as a restricted model nested within the unrestricted (7-9). The threshold estimation and multilevel structure define by [2].

$$y_{pij} = k \Leftrightarrow t^*_{pk} < y^*_{pij} < t^*_{pk+1} \tag{10}$$

$$y_{wij} = \Pi^*_w x_{wij} + \in_{wij} \tag{11}$$

$$y_{bj} = \mu^*_b + \Pi^*_b x_{bj} + \in_{bj} \tag{12}$$

where the covariance matrix $\in_{wij}$ and $\in_{bj}$ are Σ^*_w and Σ^*_b respectively. The index * refers to a further decomposition which includes the parameters to be estimated. The merged form of the structural model (4) and (6) are.

$$y_{wij} = \Lambda_w (I - B_w)^{-1} (\Gamma_w x_{wij} + \xi_{wij}) + \in_{wij} \tag{13}$$

$$y_{bj} = \nu_b + \Lambda_b (I - B_b)^{-1} (\alpha_b + \Gamma_b x_{bj} + \xi_{bj}) + \in_{bj} \tag{14}$$

First, the equations are solved in terms of the unstandardized (denoted by **) estimates, The unstandardized estimates implied by (1-6) are.

$$\Sigma^{**}_w = Cov(\in_w) = \Lambda_w (I - B_w)^{-1} \Psi_w (I - B_w)^{-1T} \Lambda^T_w + \Theta_w \tag{15}$$

$$\Sigma^{**}_b = Cov(\in_b) = \Lambda_b (I - B_b)^{-1} \Psi_b (I - B_b)^{-1T} \Lambda^T_b + \Theta_b \tag{16}$$

$$\Pi^{**}_w = \Lambda_w (I - B_w)^{-1} \Gamma_w \tag{17}$$

$$\Pi^{**}_b = \Lambda_b (I - B_b)^{-1} \Gamma_b \tag{18}$$

$$\mu^{**}_b = \nu_b + \Lambda_b (I - B_b)^{-1} \alpha_b \tag{19}$$

Let Δ_w be a *p*-dimensional diagonal matrix with 1 on diagonal if the *p*-entry is not categorical and $1/\sqrt{\Sigma^{**}_{wpp}}$ if the variable is categorical. Similarly, let δ_b be a *p*-dimensional vector with as the *p*-th entry 0 if *p*-th variable is not categorical and μ^{**}_{bp} if the *p*-th variable is categorical. To obtain the standardized estimates of the thresholds as well as the parameters in (15-19) the following definitions apply.

$$\Sigma^*_w = \Delta_w \Sigma^{**}_w \Delta_w \tag{20}$$

$$\Sigma^*_b = \Delta_w \Sigma^{**}_b \Delta_w \tag{21}$$

$$\Pi^*_w = \Delta_w \Pi^{**}_w \tag{22}$$

$$\Pi^*_b = \Delta_w \Pi^{**}_b \tag{23}$$

$$\mu^*_w = \Delta_w (\mu^{**}_b - \delta_b) \tag{24}$$

$$t^*_{pk} = \Delta_w (\tau_{pk} - \delta_b) \tag{25}$$

Finally the standardized estimates are united as σ^* in the same order as the unrestricted estimates in s. The weighted fit function is the following

$$F = (s - \sigma^*)W^{-1}(s - \sigma^*)^T \tag{26}$$

Minimizing the fit function with respect to the parameters of model (1-6) is the last stage of the estimation process. The weighted least square estimates are the parameter estimates that minimize F [2].

III. METHODHOLOGY

The analysis is performed using secondary data from the research "Development and Indicator Specification of Present Remuneration For Administrative Staff in ITS Surabaya". The effectiveness of remuneration is influenced by a number of variables, some of which are directly measurable usually call manifest variables, others are not directly measurable or latent variables. Some of researcher have had research about the relationship between the effectiveness of remuneration with performance [4],[5]. A total of 4 latent variables, 15 observed response variables and 2 observed explanatory variables are used. The latent variables are.

TABEL 1. THE OBSERVED RESPONSE VARIABLES

	Remuneration
y_1	Remuneration based on workload (grade / rank) carried
y_2	For jobs that require knowledge, skills and responsibilities are higher than other, have a higher remuneration
y_3	Income which is equivalent with private business making me feel stand working as a administrative staff in ITS
	Performance
y_4	I'm trying to be conscientious in completing tasks
y_5	I complete the work in accordance with the specified SOP
y_6	I tried to finish the work on time
	Motivation
y_7	I make every effort to overcome every obstacle I faced
y_8	I do not postpone a work given to me
y_9	I'm always trying to improve performance over time
	Characteristic of Subject Area
y_{10}	I felt that I could have a good career at where I work now
y_{11}	I love my job in a field that I do now
y_{12}	I feel comfortable working in ITS Surabaya
	Training Transfer
y_{13}	My logical reasoning power has increased after training
y_{14}	By training, I more easily understand the new tasks given to me
y_{15}	After training , I always do a job with full consideration

Meanwhile the observed explanatory variables are % of respondent who have latest educational background under diploma as x_1 and % of respondent who a man as x_2. The variables from y_1 to y_{15} are evaluated on a 5 ordered points scale ranging from 1 = "strongly disagree" to 5 = "strongly agree". Moreover note that the latent variable "Effectiveness of remuneration" is the only variable measured for the first level units and for the second level units (subject area). The hypothesized relationship between the latent variable effectiveness of remuneration, the observed indicators (measurement model), and other latent variables is defined by Figure 1.

IV. RESULT ANALYSIS

In this paper we used data from the result of the policy research survey conducted at ITS regarding the instruments of administrative staff performance which is titled "Development and Indicator Specification of Present Remuneration For Administrative Staff in ITS Surabaya". The survey population consisted of 698 administrative staff who get a remuneration while the respondents were 100 (14,33%) from 10 subject area using simple random sampling and proportional sample allocation. The data have a multilevel structure, with administrative staff nested within subject area. Of that 64% of the respondents who participated in the survey were man, 36% were woman. According to their latest background, 38% of the participant were have latest educational background as senior high school degree; 13% at diploma degree; 46% at bachelor degree; and 3% at magister degree.

Multilevel structural equation modeling is comprised of both measurement model and structural model. The multilevel measurement model, which is a multilevel confirmatory factor model, specifies how the latent factors are measured by the observed variables. The multilevel structural model contains the relationships between the latent factors [6]. The analysis is performed using a two-level structural equation model with latent variables, where the effectiveness of remuneration in individual are considered as first level units and effectiveness of remuneration in subject area as second level units.

The analysis is estimated using software Mplus 7.11 developed by Muthen, using the limited-information weighted least squares estimator indicated with "WLSMV". The analysis of the two-level data structure is firstly performed computing the intraclass correlation coefficient (ICC) for each indicator of the endogenous latent variable the effectiveness of remuneration. The ICC values for these 3 indicators ranged from 0.000 to 0.107. The results show a small level of association of the observed responses within each subject area. As a consequence, the proportion of variability due to the cluster level is very low.

The next step is analysis of the measurement model to specifies how the latent factor are measured by the observed variables. The measurement models show that the endogenous latent variable effectiveness of remuneration well measured by their respective indicators, for individual level. But in the higher level it seem that effectiveness of remuneration have a weak measured by their respective indicators. The measurement models seem significant also for the other latent variables, performance, motivation, characteristic of subject area and training transfer.

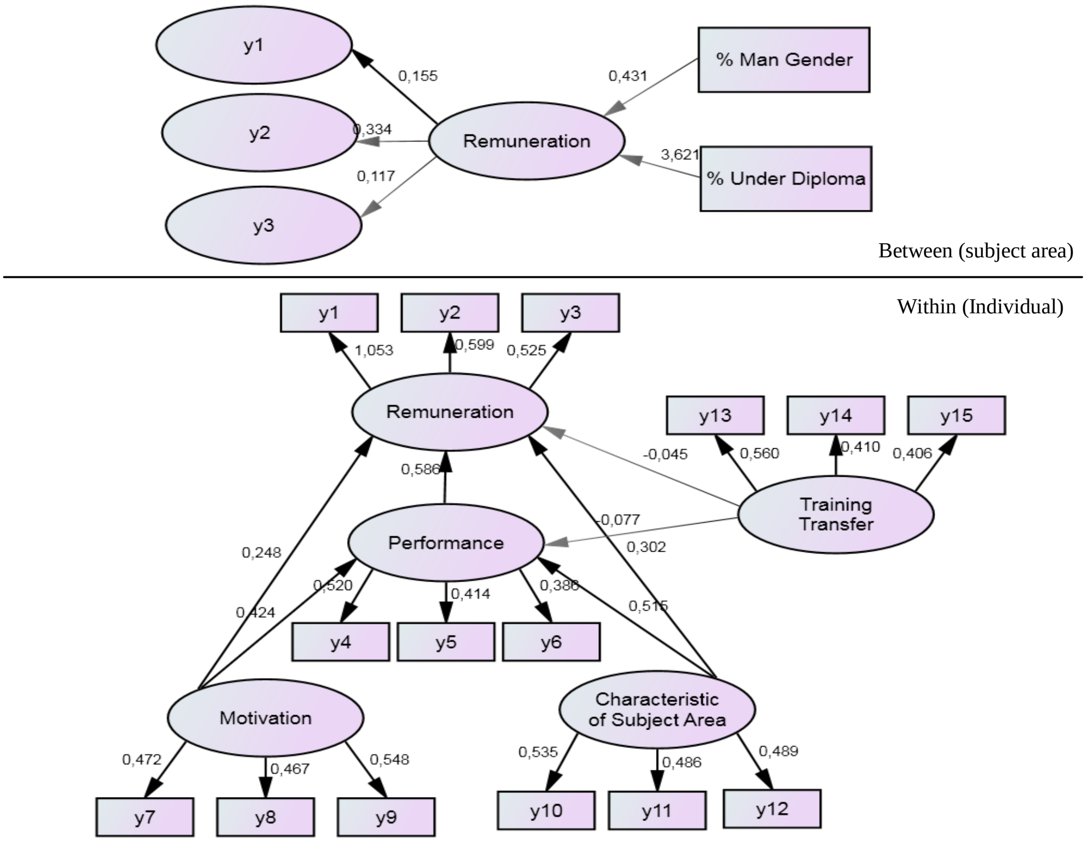

FIGURE 1. MULTILEVEL MODEL FOR EVALUATING THE EFFECTIVENESS OF REMUNERATION

In the third step, multilevel structural model was estimated both within (first) and between (second) level. The relationship between the latent variable at first level unit show that performance have a significant and positive direct effect on the endogenous latent variable, the effectiveness of remuneration. The direct effect of motivation and characteristic of subject area on effectiveness of remuneration is significant and positive. While the direct effect of training transfer on effectiveness of remuneration have a weak relationship and negative direct effect. As a result motivation and characteristics of subject area exert an indirect effect on the external effectiveness trough the performance. The indirect effect of the motivation on the effectiveness of remuneration is given by the product of the direct effects of the motivation on the performance and of the performance on the effectiveness of remuneration. Similarly, the indirect effect of the characteristic of subject area and training transfer on the effectiveness of remuneration. The analysis of the effects of the explanatory variables on the latent variable the effectiveness of remuneration in second level unit (subject area unit) have a weak influence and positive direct effect.

The last step, multilevel structural equation modeling must be evaluating with goodness of fit (fit indices). The model fit indices are acceptable. The MSEM fitted the data reasonably well with, CFI= 1,000, TLI= 1,009, and especially RMSEA= 0,000. The fit indices at this step show that hypothesis model has substantially stronger fit. The result of relationships is depicted graphically which distinguishes the within groups model (level 1), represented in the lower area of the diagram, from the between groups model (level 2), represented in the upper area of the diagram (Figure 1). The significant or strong relationships are represented with bold arrows ($p<0.10$). Weak relationships are represented with gray arrows.

V. Conclusion And Discussion

Institut Teknologi Sepuluh Nopember (ITS) Surabaya which was originally the Public Service Organization now is the State University of Law Firm which organizes state-owned and responsible for higher education in various disciplines around technology. ITS will start the implementation of the remuneration in the year 2014. If the remuneration program is perceived as fair and appropriate by the administrative staff , then the institution will be easier knowing potential administrative staff, maintain and motivate administrative staff to improve its performance so that institutions are able to produce a quality product on ultimately lead to the achievement of the vision ITS . So its necessary to evaluate the effectiveness of the remuneration for administrative staff.

The hypothesis measure of the effectiveness of remuneration is a latent variable obtained by evaluating performance with demographic factor like gender and latest education background. This model explains the effectiveness of remuneration taking into account the complex data structure where the individual are the first level units and the subject area the second level units. Cause organizations are naturally multilevel system. Individuals are nested within subject area, and they are respectively at different hierarchical levels.

The first level relationship highlights the crucial role played by the performance on the effectiveness of remuneration. Administrative staff strongly agree if higher performance have a higher remuneration too. On the performance have a direct effect the motivation, the characteristic of subject area and training transfer. The motivation, the characteristic of subject area and training transfer have also an indirect effect the effectiveness of remuneration through the performance.

The second level relationships show that % administrative staff who have a man gender and % administrative staff who have latest educational background under diploma have an influence on opinion respondent to the effectiveness of remuneration. The hypothesis model has a few limitation, some of these are attributable to the analysis method, the others to the available data. For the next step researcher can use much more data and variable. Cause in second level relationship between the effectiveness of remuneration and explanatory variables is weak. Even with this lack research, there is a belief that these results can be of some use in the policy determined and management of the stack holder in ITS Surabaya.

Acknowledgment

This research paper is made possible through the help and support from everyone. Specially thanks to all the employment in ITS Surabaya for the cooperation regarding research data.

Abstract— Events related to the survival time always happens in everyday life, one of which is time duration that need to recover from illness. Time that we need until the event happened is called survival data. Generally, not all of survival data can be observed and it is called data censored. One of statistical method that can be used to analyze and determine the survival rate of survival data is the cox proportional hazard models. In its development, the residuals of the cox proportional hazard (Cox PH) model can be used as response variable for regression function. The relationship between response variable and predictor variables often is not known the function of regression. So we are needed nonparametric regression. One of method nonparametric regression that can be used is Multivariate Regression Adaptive Spline (MARS). In this study, survival analysis is focused on the patients of HIV/AIDS which is a deadly disease. To determine survival rate of HIV/AIDS patients is used a hazard function and survival function with time duration patient stayed as variable. To know the other factors of the survival of HIV/AIDS patient is used Cox PH Models with MARS approach. The results showed that gender is one factor in the survival of HIV/AIDS patients, and treatment compliance, employment status, CD4 count, age and educational level.

Keywords: *Survival Analysis, Cox PH, MARS, HIV/AIDS*

I. INTRODUCTION

Survival analysis is a statistical analysis that is specifically used to analyze the data or cases related to the time duration until the event happened and there are data censored [1]. At first time, studied of survival is focused on the probability predictions of response, survival, average life expectancy and comparing the treatment of survival illustration experiment in humans. But survival analysis developed in the identification of risk factors and prognostic factors associated with the development of the disease [2]. One method of analysis that can be used for survival data are cox proportional hazards regression (Cox PH). Cox PH regression modeling can also be used to determine which combination of independent variables that influence in the model. In its development, Cox PH regression modeling can include relationships between predictor variables with the model function multivariate regression adaptive spline (MARS).

MARS is one of nonparametric regression method that does not depend on the assumption of a certain curve shape so it has flexibility in high dimensional data and modeling involves a lot of interaction with a few variables [3]. The variable responses in MARS modeling can use the residuals of the modeling Cox PH, so the survival modeling of MARS can be interpreted as MARS modeling the response variable is the residual result of modeling Cox PH [4]. The Previous research has been done to use of survival analysis with MARS approach in DBD cases, where the response variable of MARS models use *martingale residual* for uncensored data [5]. Then Cox proportional hazard and MARS used to analyze product sales with a electronic media system [6]. Previously, they had done research on survival analysis using MARS approach for the case of survival of heart patients in Germany, and show that the MARS method give better results than Cox PH regression [4].

In this study, the Regression Cox PH using MARS approach is used to determine the factors that influence survival of HIV/AIDS patients. Human Immunodeficiency Virus (HIV) is a virus that decrease the body's immune system so that the people affected by this virus will be susceptible to various infections and then causes *Acquired Immune Deficiency Syndrome* (AIDS). Research on HIV/AIDS in Indonesia is more emphasis on efforts to reduce the incidence of HIV/AIDS and how the healing response of

HIV/AIDS. One of them is a mixture survival modelling for HIV/AIDS cases in Semarang [7]. To determine the factors that affect the survival of HIV/AIDS.

II. LITERATURE REVIEW

A. Survival Analysis

Survival analysis is a statistical method that can be used to analyze data that related to start time (time origin) or start point until the specific event happened (end point) or failure event [8]

To determining the survival time, there are three factors required:

1. *Time origin* (starting point), is time to record and analyze an incident when the patients were first declared HIV/AIDS.
2. *Ending event of interest* (recent events) is the expired recording time. This time is useful to know the status of censored or not censored patient to be able to do analysis. Recent events in this study is the time when the HIV/AIDS patients were declared dead.
3. *Measurement scale for the passage of time* as a limit of the time of incident from the beginning to the end. The scale is measured in days, weeks, months, or years. In this study measuring scale used the time duration when the patients were suffering HIV/AIDS in months.

In survival analysis, there is difficulty data observing that is the possibility of some individual observations who cannot be observed from the start point to the end point, this situation is called the censored data [1]. In this study, there are three causes of censored data.

1. *Loss to follow up*, occurs when the patient decides to move another hospital or refuse to observe.
2. *Drop Out*, occurs the patient chooses to go home.
3. *Termination of Study*, occurs when the research period was ended while the patient has not reached the failure event.

B. Hazard Function and Survival Function

In survival analysis, there are two main functions that is survival function and hazard function [8]. Survival function is the basis of survival analysis, because it includes the probability of survival from the time varying provide important information about the survival data. Survival Function is an individual opportunity who can survive over time *t* [2], and usually denoted by.

$$S(t)=1-F(t)=1-\int_0^t f(u)\,du \tag{1}$$

$$S(t)=\exp\left[-\int_0^t \lambda(u)\,du\right] \tag{2}$$

Hazard Function is an individual probability to reach specific incidents at time interval $(t,\Delta t)$ with individual assuming to stay on at this time interval. And usually denoted by $\lambda(t)$. This function is used to express the *hazard rate* or the rate of cure and survival up to time-*t*.

$$\lambda(t)=\frac{f(t)}{S(t)} \tag{3}$$

Where $f(t)$ is probability density function (PDF) on the distribution of the estimated survival data, and it is known that:

$$\int_0^t f(u)\,du=1-S(t) \tag{4}$$

So generally, the relationship of survival function and cumulative hazard function based on that equation is as follows:

$$\Lambda(t)=-\ln\ \mathrm{S}(t) \tag{5}$$

C. Distribution Estimates

Estimation of distribution used to the survival data which in this study is duration of suffering HIV/AIDS patients to otherwise experience *failure event*. Estimation of distribution is conducted by

Anderson-Darling test (AD) because it has a strong strength and accurate if we compared with other distribution test [9].

Equation Anderson-Darling test statistic (AD) is as follows:

$$A^2 = -n - \frac{1}{n}\sum_{i=1}^{n}(2_i - 1)\left[\ln F(Y_i) + \ln F(Y_{n+1-i})\right] \tag{6}$$

Where: F = the cumulative distribution function of the conjecture distribution.
Y = survival time data.
n = number of sample

D. Cox Proportional Hazard Model

Regression modeling to determine the factors that influence survival data for uncensored data is called Cox Proportional Hazard Regression models [10]. Cox PH regression is used when the observed outcome was the length of time of an event. This Modeling is a log-linear relationship between X and the general function of hazard on T are as follows:

$$\lambda(t|X-x) = \lambda_0(t)e^{\beta x} \tag{7}$$

For variable X that has covariate, the equation used is as follows:

$$\lambda_i(t) = \lambda_0(t)e^{\beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_p x_p} \tag{8}$$

Where:

$\lambda_i(t) =$ hazard function for individual to $-i$

$\lambda_0(t) =$ baseline hazard

$\beta_1, \beta_2, \ldots, \beta_p =$ coefficient regression

$x_1, x_2, \ldots, x_p =$ variable value for individual to $-i$

The most important assumptions that must be met in the regression is Cox Proportional Hazard assumptions which means that the ratio of the hazard function is constant over time or equivalent to the statement that the ratio of the hazard function of an individual against another individual hazard function is proportional. This research will use the approach chart using log minus log survival plots to check the assumptions Proportional Hazard. According to the Cox regression model, the hazard function for failure individual-i for time-t can be written as in Equation (9) is as follows:

$$\lambda_i(t) = \lambda_0(t)\exp\left(\sum_{j=1}^{p}\beta_j x_j\right) \tag{9}$$

Modelling using Cox Proportional Hazard produces two types of residual, that is Martingale Residual and Deviance Residual that obtained from Cox Null Model. This study used Martingale Residual which serves as the response variable for modeling MARS. Residual Martingale equation is as follows:

$$M_i(t) = N_i(t) - \int_0^t Y_i(s)\lambda(s)\,ds \tag{10}$$

$$M_i(t) = N_i(t) - \hat{\Lambda}_i(t) \tag{11}$$

Where

$M_i(t)$ = Martingale Residual-i at time-t

$N_i(t)$ = The process of counting events (data uncensored given value of 1 and data censored given value of 0) for data-i at time-t

$Y_i(s)$ = Indicators, if subject-i is *under risk immediately* before-t

$\hat{\Lambda}_i(t)$ = Breslow estimator of the cumulative baseline hazard function

E. Multivariate Adaptife Regression Spline

Multivariate Adaptive Regression Splines (MARS) is one of the new flexible method for modeling high-dimensional regression data. MARS is a form of extension of the Basis Splines Functions where the number of basis function is the parameters of the model.

Some terms that need to be considered in the methods and modeling MARS is as follows,

1. *Knots* is the point of a regression line to form a region of a regression function.
2. *Basis Function* (BF) is a collection of some of the functions that are used to describe the relationship between the response variable and the predictor variable.
3. Interaction is a correlation between variables and the maximum number of interaction (MI) 1, 2, and 3.

The general equation MARS models are as follows:

$$f(x) = \alpha_0 + \sum_{m=1}^{M} \alpha_m \prod_{k=1}^{K_m} \left[s_{km} \cdot \left(x_{v(k,m)} - \tau_{km} \right) \right] + \varepsilon \tag{12}$$

Estimator model of multivariate adaptive regression splines or MARS [3]:

$$f(x) = \alpha_0 + \sum_{m=1}^{M} \alpha_m \prod_{k=1}^{K_m} \left[s_{km} \cdot \left(x_{v(k,m)} - \tau_{km} \right) \right] + \varepsilon \tag{13}$$

Where the first summation covers all the bases for a single variable functions, covering all the bases the second summation function for the interaction between two variables, the third summation includes all the base functionality for the interaction between the three variables and so on [3].

MARS modeling is determined by trial and error for the combination of BF, MI, and MO to get the value of minimum GCV. GCV equation is as follows:

$$GCV(M) = \frac{ASR}{\left[1 - \frac{\tilde{C}(M)}{N}\right]^2} = \frac{\frac{1}{N}\sum_{i=1}^{N}\left[y_i - \hat{f}_M(x_i)\right]^2}{\left[1 - \frac{\tilde{C}(M)}{N}\right]^2} \tag{14}$$

In the case of additive modeling suggested to use a value of d = 2, based on the decline in expectation value of ASR [3]. While suggests conventional value *d = 4* [1]. The smaller the value of d, the larger models which will produce with more functions of the base, and conversely the greater the value of d, the smaller models which will produce with fewer basis functions.

F. HIV/AIDS

Human Immunodeficiency Virus (HIV) is a virus that decrease the body's immune system so that the people affected by this virus will be susceptible to various infections and then causes *Acquired Immune Deficiency Syndrome* (AIDS). There are about 5 -10 million people living with HIV who do not yet show any symptoms but as a potential source of infection. AIDS is a disease that is very dangerous because it has a case fatality rate of 100% in five years, meaning that within 5 years after diagnosis of AIDS in upholding then all people will die [11]. Factors that affect the survival of people with HIV/AIDS are age, gender, education level, status employment, status marital, history ARV, absolute CD4 count, opportunistic infections, functional status, stage, and treatment compliance.

III. METHODOLOGY RESEARCH

A. Data Source

The data used in this research is secondary data on the medical records of HIV/AIDS patients in one hospital counted 100 data. Variables used in this research are:

Y : Survival Time
X_1 : Age
X_2 : Gender
X_3 : Education level
X_4 : Status of jobs
X_5 : Marital status
X_6 : History ARV

X_7 : absolute CD4 levels
X_8 : Opportunistic Infections
X_9 : Functional Status
X_{10} : Stadium
X_{11} : Compliance therapy

B. Method Analysis

a. Determine the survival data that will be used to eliminate the data censored.
b. Describing the characteristics of patients with HIV/AIDS
c. Predicting survival data distribution using the smallest of Anderson-Darling value
d. Determining the baseline hazard function
e. Estimating the survival function and cumulative hazard function
f. Using the Cox PH models to get Martingale residual,
g. Doing plotting data to know the Martingale residual predictor variables.
h. Modeling Cox PH with MARS approach through the following steps:
   1. Modeling with MARS combined Basis Function (22, 33, 44), Maximum Interaction (1, 2, 3), and the Minimum observation (0, 1, 2, 3)
   2. Getting the best model based on the value of the minimum GCV
   3. Modeling Cox Proportional Hazard with MARS approach
   4. Interpretation models
   5. Determine the level of interest for each of the significant variables in the model
i. Summing up the results of the analysis

IV. ANALYSIS AND DISCUSION

A. Descriptive Statistics

Before the description of the characteristics of patients with HIV/AIDS, then the description of the survival data were used.

TABLE 1. DESCRIPTIVE DATA SURVIVAL

N Total	n censored	n observation
100	51	49

Table 1 shows that of the 100 data obtained, there are 51 data classified in the data censored, where this data must be removed because it cannot be used in the survival analysis. It can be concluded that the survival data in this study there are as many as 49 data.

TABLE 2. DESCRIPTIVE PATIENTS HIV/AIDS

Variable	Characteristics	Number	Variable	Characteristics	Number
Age	Toddlers (0-5 years)	5	Absolute CD4 levels	>350	1
	Children (5-12 years)	1		200-350	5
	Adolescents (12-23 years)	2		<200	43
	Adults (>23 years)	41	Opportunistic Infections	< 2	17
Gender	Female	25		> 2	32
	Male	24	Functional Status	Normal	9
Education	Higher	11		Ambulatory	6
	Primary	21		lying	34
	None	17	Stadium	Stage I	12
Jobs	Working	31		Stage II	8
	Not Working	18		Stage III	15
Marital Status	Married	27		Stage IV	14
	Not Married	22	Compliance therapy	Comply	22
ARV	Ever	19		non-compliant	27

History	Never	30			

Table 2 shows the ingredients HIV/AIDS patients who experience even failure are aged above 23 years of age or older. With a CD4 count of less than 200.

B. Distribution Estimates

Estimation of the distribution is used to determine the distribution of survival data were used. The distribution function was used to estimate the survival function and cumulative hazard function. The distribution function is also used to determine the baseline hazard function which is used in the modeling.

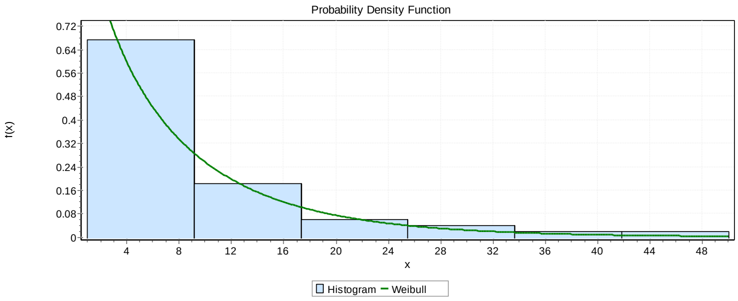

FIGURE 1. HISTOGRAM SURVIVAL DATA USED IN THE STUDY TO ESTIMATE THE DATA DISTRIBUTION.

Based on the estimation of the distribution using Anderson-Darling test, it is known that the smallest Anderson-Darling value is contained in a 2-parameter Weibull distribution in the amount of 1.93 with estimates of the parameters are and Based on estimates of parameters for two parameter Weibull distribution, then the baseline hazard function obtained are as follows :

$$\lambda_0(t|\eta,\gamma) = \frac{\gamma}{\eta}\left(\frac{t}{\eta}\right)^{\gamma-1}$$

$$= \frac{7.149}{0.859}\left(\frac{t}{0.859}\right)^{7.149-1}$$

$$= 8.322\left(\frac{t}{0.859}\right)^{6.149}$$

C. Estimated survival function and hazard function

Survival function is used to determine the probability of the patient's recovery, and cumulative hazard function is used to determine the rate of cure of HIV/AIDS. The estimation results of the survival function and the hazard function is as follows:

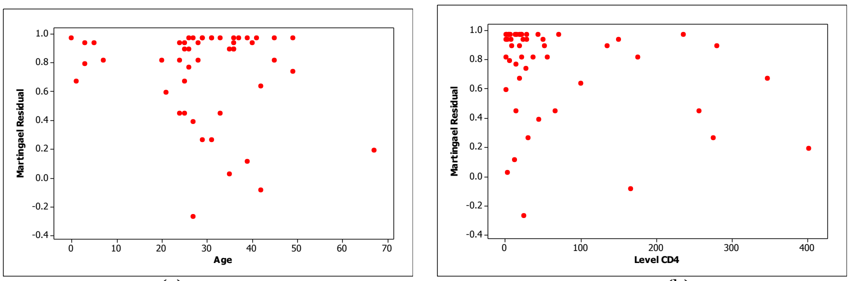
TABLE 3: ESTIMATED SURVIVAL FUNCTION AND CUMULATIVE HAZARD FUNCTION

Survival time	$S(t)$	$\Lambda(t)$	**Survival time**	$S(t)$	$\Lambda(t)$
1	0.969	0.031	14	0.666	0.406
2	0.939	0.063	15	0.575	0.553
3	0.899	0.106	16	0.542	0.612
5	0.831	0.185	18	0.478	0.738
7	0.811	0.209	24	0.445	0.810
8	0.791	0.234	27	0.412	0.887
11	0.769	0.262	28	0.377	0.976
12	0.720	0.328	36	0.337	1.087
13	0.694	0.365	50	0.281	1.269

Table 3 shows that the longer a patient is suffering from HIV/AIDS, the lower probabilities of survival for people is living with HIV/AIDS. On the contrary, the longer a patient suffering from HIV/AIDS, the higher the survival rate of patients with HIV/AIDS. It can be concluded that the probability of survival of patients with HIV/AIDS is inversely related to the survival rate of patients with HIV/AIDS.

D. Cox Proportional Hazard with Multivariate Adaptive Regression Spline

Before modeling with MARS, it is important to know the pattern of the relationship between the predictor variables and the response variable MARS modeling.



(a) (b)

FIGURE 2. SCATTER PLOT MARTINGALE RESIDUAL VS PREDICTOR VARIABLES (a) AGE, (b) THE ABSOLUTE CD4 LEVELS

Figure 2 shows that there is no particular pattern of variable X to variable Y. The pattern of relationships that do not tend to form patterns, showed that it could be used in MARS. MARS modeling done by trial and error for 36 combinations Basis Function (BF), Maximum Interaction (MI), and the Minimum Observation (MO) to get the best model based on the value of the minimum GCV.

Based on the results of trial and error combination BF, MI, and MO, the combination of which produces minimum GCV value is a combination of 22, 3, 1 with a value of GCV = 0.573 with R2 = 0.729. Based on the results of this combination, it is known MARS models produced are as follows:

$$Y = 0.721 + 0.391 * BF3 + 0.200 * BF4 - 0.001 * BF5 - 0.015 * BF7 - 0.012 * BF10$$
$$+ 0112 * BF11 - 2.603 * BF12 + 0.017 * BF14 - 0.088 * BF16 - 0.010 * BF18;$$

Where:
BF2 = (X11 = 2);
BF3 = max (0, X1 - 35,000) * BF2;
BF4 = max (0, 35,000 - X1) * BF2;
BF5 = max (0, X7 - 1000) * BF3;
BF7 = max (0, 275,000 - X7) * BF2;
BF8 = (X2 = 1) * BF2;
BF10 = max (0, X7 - 25,000) * BF8;
BF11 = max (0, 25,000 - X7) * BF8;
BF12 = (X4 = 1) * BF8;
BF14 = max (0, X7 - 257 000) * BF4;
BF16 = (X3 = 3) * BF4;
BF18 = max (0, X7 - 236,000);

Resulting in a model hazard rate or the rate of survival of patients with HIV/AIDS as follows:

$$\lambda(t) = \lambda_0(t)\exp\left(\hat{Y}\right)$$
$$= 8.322\left(\frac{t}{0.859}\right)^{6.149} \cdot \exp\begin{pmatrix} 0.721 + 0.391 * BF3 + 0.200 * BF4 - 0.001 * BF5 - 0.015 * BF7 - 0.012 * BF10 \\ +0112 * BF11 - 2.603 * BF12 + 0.017 * BF14 - 0.088 * BF16 - 0.010 * BF18; \end{pmatrix}$$

TABLE 4: INTERACTION ON BASIS FUNCTION

BF	Interactions	Specification
3 and 4	x1 and x11	Age and compliance
5	x7 * x1 and x11	CD4 levels, age and compliance
7	x7 and x11	CD4 levels and compliance
10	x2 and x11	Gender and compliance
11	x7 and x2	CD4 levels and gender
12	x7 * x2 and x11	CD4 levels, gender and adherence

14	x4 * x2 and x11	Employment, gender and adherence
16	x3* x1 and x11	The level of education, age and compliance

The Modeling results show that in general, the variables that affect the survival of patients with HIV/AIDS there are six variables: X1 (Age), X2 (Gender), X3 (Level of Education), X4 (Employment Status), X7 (Kadar CD4) and X11 (Compliance Therapy). The sixth of these variables has a good influence on the model, either individually or when interacting with other variables.

Table 4 shows the interaction of the variables that affect the survival of patients with HIV / AIDS. As for the variables that influence individual is adherence therapy and education level.

TABLE 5. VARIABLE INTEREST RATE

Variable	Importance	GCV
Gender	100	0.147
Therapy adherence	84.01	0.112
Employment Status	79.913	0.104
CD4 levels	78.947	0.102
Age	68.334	0.084
Education	16.149	0.032

Table 5 shows that gender have the largest contribution to the resulting model 100%. Then, the second largest contribution is in the amount of therapy adherence 84.010%. Then the third largest contribution is the employment status 79.913%, then the fourth biggest contribution is the Absolute CD4 cell count of 78.94%, the fifth biggest contribution is the Age of 68.334%, and the sixth biggest contribution is the level of education, amounting to 16 149.

V. CONCLUSION

HIV/AIDS patients who died is the average adult aged 23 years or older (age of majority), with CD4 levels below 200. Based on the modeling results with Cox Proportional Hazard MARS approach, which used a combination Basis Functions, Maximum interaction and minimum His observations are 22, 3, and 1 with a minimum GCV value was 0.028. Variables influencing the survival of patients with HIV/AIDS in individuals is age and compliance, levels of CD4 and compliance, gender and adherence, levels of CD4 and gender, CD4 count, gender and adherence, CD4 count, age and compliance, employment, gender and adherence, education level, age and compliance. Gender have the largest contribution to the resulting model, by 100%. Then, the second largest contribution is in the amount of therapy adherence 84.010%. Then the third largest contribution is the employment status of 79.913%, then the fourth biggest contribution is the Absolute CD4 cell count of 78.947%, the fifth biggest contribution is the Age of 68.334%, and the sixth biggest contribution is the level of education, amounting to 16.149%.

Abstract**—**Poisson regression is a member of Generalized Linear Models (GLMs) family which is derived from a Poisson distribution. Poisson distribution is a discrete distribution with the value of positive integer random variable so that it becomes a good choice for count data modeling. Poisson distribution is only determined by one parameter that defines both the mean and variance of the distribution. In Poisson regression there is an assumption that must be complete, that are mean and variance of the response variable should be the same (equidispersion). While, some of the count data potentially violates these assumptions because due to overdispersion (variance is greater than the mean). Therefore, modeling the count data is not sufficient with a simple Poisson regression. Poisson Inverse Gaussian Regression (PIGR) is a regression which is derived from mixed Poisson distribution that is designed for count data modeling with overdispersi case. PIGR will produce global model that is assumed to be valid in all areas in which the data was taken. But of course every region has different geographical conditions, social, cultural and economic. Thus, the development of a regression model that considers spatial effect, which is Geographically Weighted Regression (GWR) needs to be employed. By providing a weighting based on the location of the region, the GWR models will generate different local models for each region. Furthermore, the response variable must follow the PIG distribution so development will be Geographically Weighted Poisson Inverse Gaussian Regression (GWPIGR). Parameter estimation is done using Maximum Likelihood Estimation (MLE) and hypothesis testing conducted by Maximum Likelihood Ratio Test (MLRT).

Keywords: *Geographically Weighted Poisson Inverse Gaussian Regression, Maximum Likelihood Estimation, Maximum Likelihood Ratio Test.*

I. INTRODUCTION

Poisson regression is one of the family members of Generalized Linear Models (GLMs) derived from a Poisson distribution. Poisson distribution is a discrete distribution with the value of the random variable a positive integer so it becomes a good choice for discrete data modeling. Poisson distribution is determined solely by a single parameter that defines both the mean and variance of the distribution. Thus, in a Poisson regression there is an assumption that must be fulfilled which is the mean and variance of the response variable should be the same (equidispersion). But most of the discrete data found in the case suffer overdispersion [1].

But in reality these assumptions violations often occur when variance is smaller than the mean (underdispersion) or variance is greater than the mean (overdispersion). To overcome overdispersion case, some form of statistical model is employed by mixing Poisson distribution with the other distribution both discrete and continuous (mixed Poisson distribution). Mixed Poisson distribution is an alternative solution to overcome overdispersion case, but only a few distributions that are often used in research due to complicated calculations. One of them is the Poisson Inverse Gaussian distribution (PIG) which is the mix of Poisson distribution with random effects that follow Inverse Gaussian distribution. This distribution was first introduced by Holla in 1966 [2].

The development of regression models that considers the spatial heterogeneity, is called Geographically Weighted Regression (GWR). By providing a weighting based on the position or distance of an observation area with the observation area other then GWR models will produce local models that vary in each region. So this research using modeling Poisson Inverse Gaussian Geographically Weighted Regression (GWPIGR).

II. METHODS

Regression analysis is a statistical method used to model the relationship between the response variable and one or more predictor variables. Not all regressions have a response variable that follows a normal distribution. If the response variable follows the Poisson Inverse Gaussian distribution (PIG), then the regression is called regression PIG. Regression PIG includes global regression, while the local form of PIG called Geographically Weighted Regression Poisson Inverse Gaussian (GWPIGR).

A. Poisson Distribution

Poisson distribution is a probability distribution for the events that happen rarely, where the observation depends on the specific time intervals or in a particular area with a discrete response and one or more independent predictor. The time interval can be measured in minute, day, week, month, even year [3]

Probability density function follows:

$$p(y;\ \mu) = \frac{e^{-\mu}\mu^{y}}{y!} \text{ for } y = 0, 1, 2, \ldots \text{ and } \mu > 0 \tag{1}$$

With mean and variance of the same value is determined by:

$$E(Y) = Var(Y) = \mu \tag{2}$$

B. Inverse Gaussian Distribution

Inverse Gaussian has two parameters and probability density function that can be written as follows:

$$f(y) = (2\pi y^3\sigma)^{-0,5} e^{-(y-\mu)^2/2y\mu^2\sigma^2}, y > 0 \tag{3}$$

With mean and variance are written as:

$$E(Y) = \mu \text{ and } Var(Y) = \sigma^2\mu^3 \tag{4}$$

Where σ^2 is the parameter of dispersion. Inverse Gaussian is used in cases with extreme skewness. The name itself comes from the inverse Gaussian cumulant function which has inverse relationship with kumulant function (the natural logarithm of the function of MGF) normal distribution / Gaussian distribution [4].

C. Poisson Inverse Gaussian Distribution

PIG probability density distribution can be calculated as follows:

$$P(Y = y|\mu) = \frac{\mu^y e^{\frac{1}{\tau}}}{y!}\left(\frac{2}{\pi\tau}\right)^{\frac{1}{2}}(2\mu\tau + 1)^{-\left(\frac{y-\frac{1}{2}}{2}\right)} K_{y-\frac{1}{2}}\left(\frac{1}{\tau}\sqrt{2\mu\tau + 1}\right) \tag{5}$$

While Bessel functions [5] is:

$$K_{\frac{1}{2}}(a) = K_{-\frac{1}{2}}(a) = \left(\frac{\pi}{2a}\right)^{\frac{1}{2}} e^{-a},$$
$$K_{\frac{3}{2}}(a) = \left(1 + \frac{1}{a}\right)K_{\frac{1}{2}}(a). \tag{6}$$

D. Poisson Inverse Gaussian Regression

Poisson Inverse Gaussian Regression model can be written as follows:

$$y_i \sim PIG\ [\mu_i]$$
$$\mu_i = e^{\mathbf{x}_i^T\beta} \text{ or } ln(\mu_i) = \mathbf{x}_i^T\boldsymbol{\beta} \tag{7}$$

With

$$\mathbf{x}_i{}^T = [1 \quad x_{1i} \quad x_{2i} \quad \cdots \quad x_{ki}]$$
$$\boldsymbol{\beta} = [\beta_0 \quad \beta_1 \quad \beta_2 \quad \cdots \quad \beta_k]^T$$

Where $i = 1, 2, \ldots, n$ is the number of observations.

Probability density function follows::

$$P(Y = y_i|\mathbf{x}_i;\boldsymbol{\beta};\tau) = \left\{\frac{e^{\mathbf{x}_i^T\boldsymbol{\beta}y_i}e^{\frac{1}{\tau}}}{y_i!}\left(\frac{2}{\pi\tau}\right)^{\frac{1}{2}}\left(2^{e^{\mathbf{x}_i^T\boldsymbol{\beta}}}\tau+1\right)^{-\frac{\left(y_i-\frac{1}{2}\right)}{2}}K_{si}(z_i)\right\} \tag{8}$$

E. Procedures

Step 1. Determine the density function of the opportunities GWPIGR models. Step 2. Determine GWPIGR likelihood function on the model. Step 3. Determine the natural logarithm of the likelihood function. Step 4. Calculate first partial derivative of the natural logarithm function. Step 5. Calculate the second partial derivative of the natural logarithm function. Step 6. Calculate estimates $\boldsymbol{\beta}$ and τ. If the previous steps resulting equation that is not close the form, Fisher Scoring Algorithm is employed. Step 7. Do hypothesis testing simultaneously using MLRT and partialy using Z-test.

III. RESULT AND DISCUSSION

Spatial data is data collected from different spatial locations and indicates the existence of dependence between the measurement data by location. Consequently, if data model using ordinary linear regression, it will generate autocorrelation and heterogeneity in the data. There are several methods to overcome the problem, one of them is the Geographically Weighted Regression Poisson Inverse Gaussian method using Maximum Likelihood Estimation (MLE).

A. Parameter Estimation Geographically Weighted Poisson Inverse Gaussian Regression Model

Geographically Weighted Poisson Inverse Gaussian regression is a method that can be used to analyze the data count suffering overdispersion by considering the spatial aspect. This research will be carried out with the parameter estimation using Maximum Likelihood Estimation (MLE).

Geographically Weighted Poisson Inverse Gaussian Model:

$$\begin{aligned}\mu(u_i,v_i) &= exp\left(\beta_0(u_i,v_i)+\beta_1X_{1i}(u_i,v_i)+\beta_2X_{2i}(u_i,v_i)+\cdots+\beta_kX_{ki}(u_i,v_i)\right)\\ &= e^{\mathbf{x}_i^T\boldsymbol{\beta}(u_i,v_i)}\end{aligned} \tag{9}$$

Where y_i is the value of the response variable observation i[th] location, x_{ik} is the value of predictor variable k observation at (u_i,v_i) locations, dan $\beta_k(u_i,v_i)$ is the regression coefficient for each location (u_i,v_i).

The first step in determining the parameter estimation is to determine the density function opportunities:

$$P(Y = y_i|\boldsymbol{x}_i;\boldsymbol{\beta};\tau) = \frac{e^{\mathbf{x}_i^T\boldsymbol{\beta}(u_i,v_i)y_i}e^{\frac{1}{\tau}}}{y_i!}\left(\frac{2}{\pi\tau}\right)^{\frac{1}{2}}\left(2e^{\mathbf{x}_i^T\boldsymbol{\beta}(u_i,v_i)}\tau+1\right)^{-\frac{\left(y_i-\frac{1}{2}\right)}{2}}K_{si}(z_i) \tag{10}$$

The second step determines the likelihood function of the density function chances

$$L(\boldsymbol{\beta},\tau) = \prod_{i=1}^{n}\frac{e^{\mathbf{x}_i^T\boldsymbol{\beta}(u_i,v_i)}e^{\frac{1}{\tau}}}{y_i!}\left(\frac{2}{\pi\tau}\right)^{\frac{1}{2}}\left(2e^{\mathbf{x}_i^T\boldsymbol{\beta}(u_i,v_i)}\tau+1\right)^{-\frac{\left(y_i-\frac{1}{2}\right)}{2}}K_{si}(z_i) \tag{11}$$

The third step is to transform the likelihood function ln:

$$\begin{aligned}l(\boldsymbol{\beta}(u_i,v_i),\tau) = &\sum_{i=1}^{n}y_i\ln\left(e^{\mathbf{x}_i^T\boldsymbol{\beta}(u_i,v_i)}\right)+\frac{n}{\tau}-\ln\left(\sum_{i=1}^{n}y_i!\right)+\frac{n}{2}\ln\left(\frac{2}{n}\right)-\frac{n}{2}\ln\tau\\ &-\sum_{i=1}^{n}\left(\frac{2y_i-1}{4}\right)\ln\left(2e^{\mathbf{x}_i^T\boldsymbol{\beta}(u_i,v_i)}\tau+1\right)+\sum_{i=1}^{n}\ln K_{si}(Z_i)\end{aligned} \tag{12}$$

The fourth step is to find the first partial derivatives of the parameters $\beta(u_i,v_i)$ of the natural logarithm function by adding a weighting:

$$\frac{\partial l^*}{\partial\boldsymbol{\beta}(u_i,v_i)} = \sum_{i=1}^{n}\left\{\left(y_i - M_{(y_i)}(w_{ij})e^{\mathbf{x}_i^T\boldsymbol{\beta}(u_i,v_i)}\right)x_i^T\right\} \tag{13}$$

Next is determine first partial derivatives of the parameters τ:

$$\frac{\partial l^*}{\partial\tau} = \sum_{i=1}^{n}\left\{-\frac{1}{\tau^2}+\frac{M_{(y_i)}(w_{ij})\left(e^{\mathbf{x}_i^T\boldsymbol{\beta}(u_i,v_i)}\tau+1\right)}{\tau^2}-\frac{y_i}{\tau}\right\} \tag{14}$$

ISBN 978-602-74529-0-9

Where

$$M_{(y_i)} = \frac{1}{\sqrt{2e^{x_i^T\beta(u_i,v_i)}\tau+1}} \frac{K_{y_i+\frac{1}{2}}(z)}{K_{y_i-\frac{1}{2}}(z)} \tag{15}$$

The fifth step is to determine a second partial derivatives against $\beta(u_i,v_i)$ and τ. The second derivatives are written as follows:

$$\frac{\partial^2 l^*}{\partial\beta\partial\beta^T} = \frac{\sum_{i=1}^{n}\left\{\left(y_i - M_{(y_i)}(w_{ij})e^{x_i^T\beta(u_i,v_i)}\right)x_i^T\right\}}{\partial\beta^T} \tag{16}$$

For the next is the first derivative of the β second descent to τ

$$\frac{\partial^2 l}{\partial\beta\partial\tau} = \frac{\sum_{i=1}^{n}\left\{\left(y_i - M_{(y_i)}(w_{ij})e^{x_i^T\beta(u_i,v_i)}\right)x_i^T\right\}}{\partial\tau} \tag{17}$$

The next second derivative is the second derivative of the likelihood function of the first derivative τ, is:

$$\frac{\partial^2 l}{\partial^2\tau} = \frac{\sum_{i=1}^{n}\left\{-\frac{1}{\tau^2}+\frac{M_{(y_i)}(w_{ij})\left(e^{x_i^T\beta(u_i,v_i)}\tau+1\right)}{\tau^2}-\frac{y_i}{\tau}\right\}}{\partial\tau} \tag{18}$$

From the results of the above derivative obtained explicit equation then to solve these equations RS algorithm and CG algorithm are employed. Likelihood function is maximized by using Fisher Scoring Algorithm. If the above equation and non-linear implicit equations within the parameters $\boldsymbol{\beta}$ and τ so as to obtain estimates of the parameters $\boldsymbol{\theta} = [\boldsymbol{\beta}^T \quad \tau]$, function is maximized by using Fisher Scoring Algorithm, by the following equation:

$$\hat{\boldsymbol{\theta}}_{(r+1)} = \hat{\boldsymbol{\theta}}_{(r)} + \mathbf{I}^{-1}\left(\hat{\boldsymbol{\theta}}_{(m)}\right)\mathbf{D}\left(\hat{\boldsymbol{\theta}}_{(m)}\right), \tag{19}$$

Where

$$\hat{\boldsymbol{\theta}} = \left(\hat{\boldsymbol{\beta}}^T, \hat{\tau}\right) \tag{20}$$

$$\boldsymbol{D}\left(\hat{\boldsymbol{\theta}}\right) = \left(\frac{\partial l}{\partial\hat{\tau}}, \frac{\partial l}{\partial\hat{\boldsymbol{\beta}}^T}\right)^T \tag{21}$$

$$\mathbf{I}\left(\hat{\boldsymbol{\theta}}_{(m)}\right) = -E\begin{bmatrix} \frac{\partial^2 l}{\partial\tau^2} & \frac{\partial^2 l}{\partial\tau\partial\boldsymbol{\beta}} \\ \frac{\partial^2 l}{\partial\boldsymbol{\beta}\partial\tau} & \frac{\partial^2 l}{\partial\boldsymbol{\beta}^T\partial\boldsymbol{\beta}} \end{bmatrix} \tag{22}$$

$$\mathbf{H}\left(\hat{\boldsymbol{\theta}}_{(m)}\right)_{(k+1)(k+1)} = \begin{bmatrix} \frac{\partial^2 l}{\partial\tau^2} & \frac{\partial^2 l}{\partial\tau\partial\boldsymbol{\beta}} \\ \frac{\partial^2 l}{\partial\boldsymbol{\beta}\partial\tau} & \frac{\partial^2 l}{\partial\boldsymbol{\beta}^T\partial\boldsymbol{\beta}} \end{bmatrix}_{\theta=\theta_{(m)}} \tag{23}$$

Hessian matrix is a matrix that contains the second derivative of the likelihood function of the parameter $\boldsymbol{\beta}$ and τ. The steps as follows Fisher Scoring Algorithm:

1) Determining the initial vector parameter $\hat{\boldsymbol{\theta}}_0$ with assuming the data meet the multiple linear regression model.
2) Forming gradient vector $\mathbf{D}\left(\hat{\boldsymbol{\theta}}\right)$ by substituting equation (13) and (14) into the equation $\mathbf{D}\left(\hat{\boldsymbol{\theta}}\right)$
3) Hessian matrix forming (23) by substituting equation (16), (17), and (18) into the equation (22)
4) Fisher information matrix formed $\mathbf{I}\left(\hat{\boldsymbol{\theta}}_{(0)}\right)$
5) inserting values $\hat{\boldsymbol{\theta}}_{(0)}$ thus obtained gradient vector $\mathbf{D}\left(\hat{\boldsymbol{\theta}}_{(0)}\right)$ and hessian matrix $\mathbf{H}\left(\hat{\boldsymbol{\theta}}_{(0)}\right)$
6) Starting from $m = 0$ iterating the equation $\mathbf{I}^{-1}\left(\hat{\boldsymbol{\theta}}_{(m)}\right)$, value $\hat{\boldsymbol{\theta}}_{(m)}$ is a set of parameter estimator convergent iteration to- m.

7) If you have not obtained when the parameter estimation convergent iteration to- m, then proceed back to step 6 to iteration to- $m+1$. Iteration will stop when the value of $\| \hat{\boldsymbol{\theta}}_{(m+1)} - \hat{\boldsymbol{\theta}}_{(m)} \| \leq \varepsilon$ and $\varepsilon > 0$ is a very small number [6].

B. Statistical Test

Parameter and hypothesis testing in the model are done simultaneously using MLRT and partially using Z-test. The test statistic used in the simultaneous test likelihood ratio is a statistical measure that was formed by determining the parameters set under the population and under the null hypothesis.

Hypotheses to test the significance of the parameters $\boldsymbol{\beta}$.

H_0: $\beta_1(u_1, v_1) = \beta_2(u_2, v_2) = \cdots = \beta_k(u_k, v_k) = 0$

H_1: at least one $\beta_l(u_l, v_l) \neq 0$ with $l = 1, 2, \ldots, k$

Here is a statistical test used:

$$G = -2\, ln\left(\frac{L(\hat{\omega})}{L(\hat{\Omega})}\right) \tag{24}$$

in which the value of $L(\hat{\omega})$ and $L(\hat{\Omega})$ are the maximum likelihood value for each model in which $\hat{\boldsymbol{\beta}}$ and $\hat{\tau}$ is the result of parameter estimation. Determine the rejection region H_0 if $G_{hit} > \chi^2_{(\alpha,v)}$.

For the partial test parameter β using the hypotheses:

H_0: $\beta_l(u_i, v_i) = 0$

H_1: $\beta_l(u_i, v_i) \neq 0$, with $l = 1, 2, \ldots, k$

Here is a statistical test used

$$Z = \frac{\hat{\beta}_l}{SE(\hat{\beta}_l)} \tag{25}$$

To reject H_0 if $|Z_{hit}| > Z\alpha_{/2}$ where α is the significance level used.

While the partial test parameter τ using the hypotheses:

H_0: $\tau = 0$

H_1: $\tau \neq 0$

Here is a statistical test used:

$$Z = \frac{\hat{\tau}}{SE(\hat{\tau})} \tag{26}$$

To reject H_0 if $|Z_{hit}| > Z\alpha_{/2}$ where α is the significance level used.

IV. CONCLUSION

Parameter estimation of Geographically Weighted Poisson regression model using the Inverse Gaussian Maximum Likelihood Estimation (MLE). In the process of parameter estimation, equation obtained is not close the form, so it requires iteration method employing Fisher Scoring Algorithm. Hypothesis testing is done simultaneously using Maximum Likelihood Ratio Test and partially using Z-test .

Abstract—Extreme precipitation is a rare natural phenomenon categorized as one of extreme climates indicator. It leads to natural disasters such as floods and landslides. Prediction of precipitation return level, i.e. quantile which has probability 1/m of being exceeded in m period, become quite important to reduce the negative impact caused by this extreme event. The link between observation recorded on a particular time frame and quantities of longer time scales such as return level is provided by Extreme Value Theory (EVT) commonly used to learn the behaviors of extreme events. Given the observations are recorded from several locations, the extreme events at different locations are driven by geographical and climatologically factors. Unfortunately, the data of these factors are not always available. In this study, the spatial Bayesian hierarchical model (BHM) was employed to update the information in the likelihood that is not fully described by those unobservable covariates. The proposed method was applied to predict the extreme precipitation return level in Lamongan district, East Java, Indonesia. The Peak Over Threshold (POT) scheme was used to obtain extreme observations. The prior distribution was employed to update the likelihood of Generalized Pareto Distribution as an asymptotic distribution of exceeding resulted from POT procedure. The empirical results showed that the return level got higher for longer periods.

Keywords: *Extreme value theory, Peaks Over Threshold, Bayesian hierarchical model, spatial, return level.*

I. INTRODUCTION

Extreme value theory (EVT) is a method that is commonly used to analyze extreme natural events. Such extreme events associated with the location are called spatial extreme value. The intensive rain that usually happens during the rainy season can cause floods and landslides. These disasters are examples of negatives effect caused by extreme events. The studies to learn these extreme phenomena are quite important to predict and anticipate their occurrence in the future.

The EVT is used to analyze the heavy-tailed distribution of the extreme events. There are two approaches used EVT: (i) Block Maxima (BM) approach that has the Generalized Extreme Value (GEV) distribution and (ii) Peaks over Threshold (POT) approach that follows the Generalized Pareto Distribution (GPD) distribution. These research employed POT scheme. The characteristics of the GPD are expressed by the three parameters of EVT, i.e. threshold (u), scale (σ), and shape (ξ).

One of the most important things in the EVT is to calculate the value of return level, i.e. the probability of occurrence of a particular level of extreme events in the coming period. Knowledge of the return level is important for disaster mitigation and for the preparation of long-term programs [1]. This paper discusses the procedures to obtain the parameters estimates GPD and to calculate the return level using Bayesian Hierarchical Model (BHM). The BHM is chosen because it has some advantages, for instance, it able to accommodate geography and climatology at each level of the hierarchy structure.

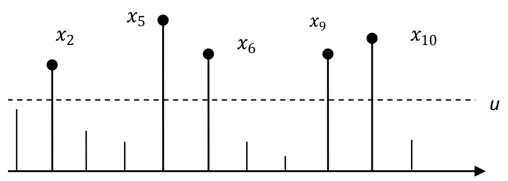
This paper is organized as follows. This section is followed by a section for a method that briefly discuss POT and BHM. The next part is used to describe the data and research methodology. The last part gives conclusion and suggestions.

II. LITERATURE REVIEW

In this part is discussed how the procedure was done to model the spatial extreme value by using the POT approach that follows GPD combined with BHM.

A. *Peaks Over Threshold (POT)*

POT is one of the methods to identify the extreme value by using the so-called threshold (u) as a reference value. The data above the threshold will be identified as extreme values. Figure 1 shows how to collect extreme data using POT. The values of x_2, x_5, x_6, x_9, and x_{10} are larger than the threshold (u) therefore these six data are considered as extreme values that will be used in further analysis.



F FIGURE 1. ILLUSTRATION OF EXTREME DATA COLLECTION USING POT

The higher threshold is the higher probability that the extremes will approach the GPD [2]. The probability density function (pdf) of GPD is formulated as follow:

$$f\left(x-u\right)=\begin{cases}\dfrac{1}{\sigma}\left(1+\dfrac{\xi\left(x-u\right)}{\sigma}\right)^{-\frac{1}{\xi}-1} & ,\xi\neq 0\\[2ex] \dfrac{1}{\sigma}\exp\left(-\dfrac{\left(x-u\right)}{\sigma}\right) & ,\xi=0\end{cases}\tag{1}$$

where $0 \le \left(x-u\right) \le \infty$ if $\xi \ge 0$ and $u \le \left(x-u\right) < u-\frac{\sigma}{\xi}$ if $\xi < 0$. The σ and ξ in (1) represent scale parameter and shape parameter (the tail index), respectively.

B. *Parameter Estimation of Generalized Pareto Distribution*

Parameter estimation of GPD can be done using several ways. One of them commonly used is a Maximum Likelihood Estimation (MLE) that maximizes the likelihood function of $y_1, y_2, \ldots, y_n$, where $y = x-u$. Therefore, the equation (1) is rewritten in (2) as follows:

$$f\left(\xi,\sigma,y\right)=\begin{cases}\dfrac{1}{\sigma}\left(1+\dfrac{\xi y}{\sigma}\right)^{-\left(\frac{1}{\xi}+1\right)} & ,\xi\neq 0\\[2ex] \dfrac{1}{\sigma}\exp\left(-\dfrac{y}{\sigma}\right) & ,\xi=0\end{cases}\tag{2}$$

The log-likelihood function of (2) is expressed as:

$$\ln L\left(\xi,\sigma\left|y_1,y_2,\ldots,y_n\right.\right)=-n\ln\sigma-\left(\frac{1}{\xi}+1\right)\sum_{i=1}^{n}\ln\left(1+\frac{\xi y_i}{\sigma}\right)\tag{3}$$

The first derivative of log-likelihood with resct to each parameters are:

$$\frac{\partial \ln L}{\partial \xi} = \frac{1}{\xi^2}\sum_{i=1}^{n}\ln\left(1+\frac{\xi y_i}{\sigma}\right)-\left(\frac{1}{\xi}+1\right)\sum_{i=1}^{n}\frac{y_i}{\left(\sigma+\xi y_i\right)} \tag{4}$$

$$\frac{\partial \ln L}{\partial \sigma} = \sigma^{-1}\left(-n+\left(1+\xi\right)\sum_{i=1}^{n}\frac{y_i}{\sigma+\xi y_i}\right) \tag{5}$$

The solution for shape parameter estimate using MLE is not close form. The Newton-Raphson was employed to solve this issue.

C. Determination of the Threshold

The extreme values were obtained once the threshold (*u*) was determined as a reference value. The determination of the threshold aims to find the optimum balance in order to obtain the minimum error. In this paper, the Mean Residual Life Plot (MRLP) was used to determine the threshold with the following steps.

1. First, making the MRP with the coordinates of the points based on the following equation,

$$\left\{\left(u, \frac{1}{n_u}\sum_{i=1}^{n_u}\left(x_{(i)}-u\right)\right): u < x_{maks}\right\} \tag{6}$$

   where n_u is the number of observations above the threshold. The linear function of *u* is:

$$E\left(X-u \middle| X>u\right) = \frac{\sigma_u}{1-\xi} = \frac{\sigma_{u_0}+\xi\left(u-u_0\right)}{1-\xi}\ , \tag{7}$$

   where u_0 is extreme threshold value and σ_u is the scale parameter changes.

2. Chosen value threshold point when the plot began to form a linear pattern around the value of *u*.

D. Autocorrelation Function (ACF)

In this paper, the ACF was employed to detect if the extreme values larger than the threshold has a stochastic nature. Stochastic nature is random nature that can only be explained by a distribution [3]. Therefore, when the ACF is not significant or stationary, it is necessary to declustering data that take the extreme values of the highest in the range (*r*) determined in advance using the extremal index at (8) [4].

$$\vartheta = \begin{cases} \min\left\{1, \dfrac{2\left(\sum_{i=1}^{N-1} T_i\right)^2}{\left(N-1\right)\sum_{i=1}^{N-1} T_i^{\,2}}\right\} & \text{if } \max\left\{T_i : 1 \le i \le N\right\} \le 2 \\ \min\left\{1, \dfrac{2\left(\sum_{i=1}^{N-1}\left(T_i-1\right)\right)^2}{\left(N-1\right)\sum_{i=1}^{N-1}\left(T_i-1\right)\left(T_i-2\right)}\right\} & \text{if } \max\left\{T_i : 1 \le i \le N\right\} > 2 \end{cases} \tag{8}$$

E. Clustering the Location

Grouping of locations used to obtain shape parameter that estimated from stationary process. In this paper, if the slope values that are not stationary, then the groupings of locations with non-hierarchical clustering method, i.e. *k*-mean cluster, was employed. The number of groups was determined using the average value of silhouette coefficient calculated as in (9) [5]:

$$S\left(j\right) = \frac{\min\left(B\left(j,k\right)\right)-O\left(j\right)}{\max\left(O\left(j\right),\left(B\left(j,k\right)\right)\right)} \tag{9}$$

ISBN 978-602-74529-0-9

where $B(j,k)$ denotes the average distance the members j with other members from different cluster and $O(j)$ describes the average distance between the member j to other members in the same cluster.

F. Bayesian Hierarchical Model (BHM)

The purpose of using BHM is to accommodate geographical and climatological information into the distribution of parameters and to update the parameters through the data that were known as a posterior distribution. The posterior distribution was determined by the following Bayes theorem.

$$z_{k,j,i} = c_{k,j} \times y_{k,j,i} \tag{10}$$

$$p\left(\boldsymbol{\theta}_1, \boldsymbol{\theta}_2 \middle| \mathbf{Z}(\vec{\mathbf{s}})\right) = p_1\left(\mathbf{Z}(\vec{\mathbf{s}}) \middle| \boldsymbol{\theta}_1\right) \times p_2\left(\boldsymbol{\theta}_1 \middle| \boldsymbol{\theta}_2\right) \times p_3\left(\boldsymbol{\theta}_2\right), \tag{11}$$

where $c_{k,j}$ is the constant transformation of resulting the cluster, $z_{k,j,i}$ is the result of the transformation in the cluster k, station j, and observation i. The p_1 is joint probability (or likelihood), p_2 is conditional prior distribution, and p_3 is prior distribution. The parameters in (11) are $\boldsymbol{\theta}_1 = [\phi, \xi]^{-1}$ and $\boldsymbol{\theta}_2 = [\alpha, \beta]^{-1}$ where ϕ, and ξ are scale and shape parameters in likelihood. The α and β are parameters in layer process.

III. DATA AND RESEARCH METHODOLOGY

This section discusses how to obtain estimates of the parameters and return level for the modeling of extreme precipitation events using BHM. The softwares used in this work are openBugs, Microsoft Excel, and R. The proposed method was applied to model rainfall data observed in six locations in Lamongan district, East Java, Indonesia.

A. Data and Pre-Processing

Pre-processing the data used to identify the missing value, outliers, and the observations that do not fit the requirement. The Microsoft Excel was used for pre-processing and open-source software R was used to calculate descriptive statistics such as histograms and normality plot, see [6].

TABLE 1. DATA STRUCTURE

Year	**Month**	**Station / Observation**	***S*$_1$**		***S*$_2$**		**…**	***S*$_{21}$**	
			***u*$_1$**	***v*$_1$**	***u*$_2$**	***v*$_2$**		***u*$_{21}$**	***v*$_{21}$**
1981	1	1	$x_{1,1}$		$x_{2,1}$		…	$x_{21,1}$	
1981	1	2	$x_{1,2}$		$x_{2,2}$		…	$x_{21,2}$	
⋮	⋮	⋮	⋮		⋮		⋱	⋮	
2013	12	108	$x_{1,n}$		$x_{2,n}$		…	$x_{21,n}$	

B. Sampling Extreme Value of the Data

1. Installing EVA packages in R used to analyze extreme value.
2. Activating extreme toolkit and create MRLP for a specified interval.
3. Identifying the mean residual life plot, find upper and lower bounds that are stable on the plot. Use the lower and upper limits of the modified parameters to make the plot of scale and shape parameters. Next, select the appropriate threshold values based on the results of the modified parameter plot.
4. Collecting extreme data above the threshold value.
5. The data obtained were tested with ACF plot. When there is no significant lag (stationary), then test the GPD using Anderson-Darling test [3]. If it is not stationary yet, then the declustering must be done.
6. A grouping station using the *k*-mean method and fill it with the value Silhouette as in (9) to obtain a proper number of the cluster.

C. Parameter Estimation with BHM

1. Compiling the Directed Acyclic Graph (DAG) to see the relationship between the data, parameters of the model, and the prior distribution using openBugs software [7].
2. Determining the initial value for each parameter to be estimated.

3. Determining prior for $\alpha_{\phi,i}, \beta_{\phi,0}, \beta_{\phi,1}$ and ξ as the parameters in layer process and likelihood.

D. *Application to Real Data*

The steps described before were applied to rainfall data in Lamongan district observed in seven locations. The data used is daily rainfall data span from 1981 to 2013. The first step done is determining the threshold value. Input the data into Microsoft Excel CSV (MC-DOS) and compile it into extreme toolkit already activated by typing "library (extRemes)" in R, as shown Figure 2. The MRLP, modified shape, scale and all about extreme value using extremes toolkit were produced as displayed in Figure 3.

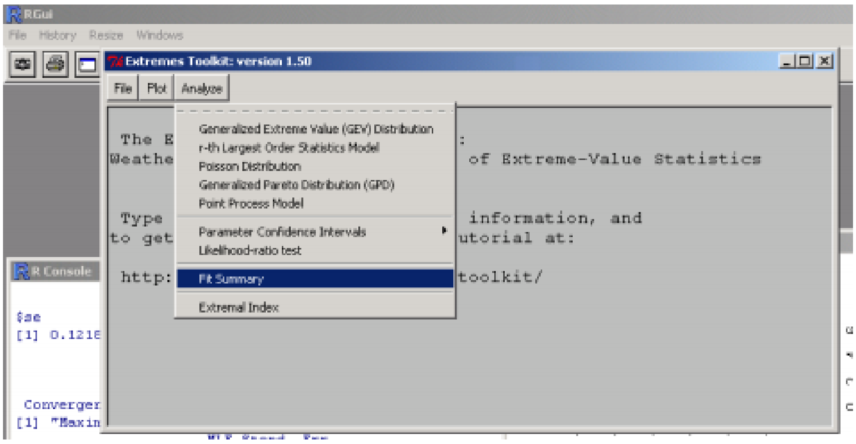


FIGURE 2. EXTREME TOOLKIT

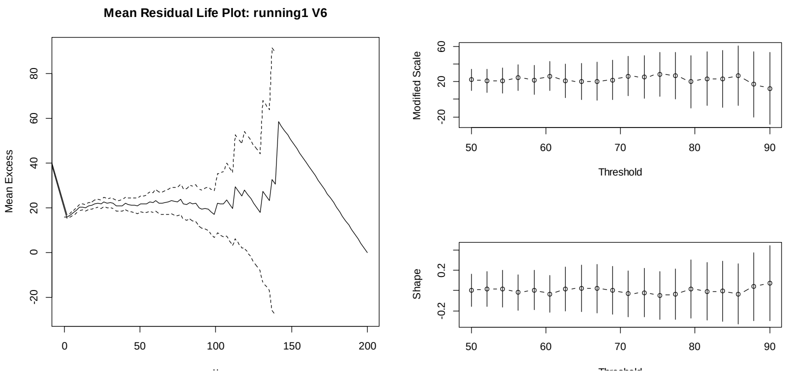

FIGURE 3. MRLP (LEFT) AND MODIFIED SCALE AND SHAPE PARAMETER PLOT (RIGHT)

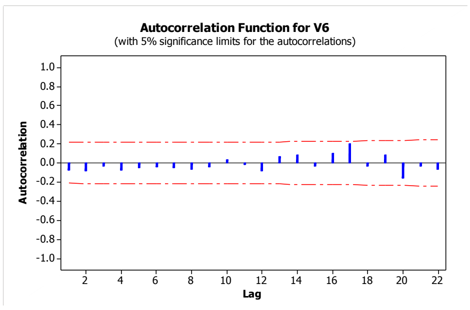
As shown in Figure 3, the threshold limit (u) 60 began to show instability. Creating the ACF plot and conducting Anderson Darling's test (using EVA package in R) determine if the extreme data complies the distribution, i.e. GPD. If the test ACF insignificant and Anderson darling's test show that the GPD is satisfied, then the next step is doing declustering to take samples again. But, if the test does not meet the GPD, it is necessary to re-determine the threshold.



LOCATIONS	STATISTIC	P-VALUE	REMARKS
BABAT	0.5892	0.2637	NOT REJECT H0
BLAWI	0.7621	0.1226	NOT REJECT H0
KARANGBINANGUN	0.8546	0.1036	NOT REJECT H0
KEDUNGPRING	0.5692	0.2658	NOT REJECT H0
LAMONGAN	0.8615	0.0927	NOT REJECT H0
PANGKATREJO	0.6521	0.2234	NOT REJECT H0
SUKODADI	0.4848	0.3683	NOT REJECT H0

FIGURE 4. ACF PLOT (LEFT) AND THE RESULT OF ANDERSON DARLING TEST (RIGHT)

The ACF plot for Blawi station is displayed in Figure 3 (left). The plot shows that the extreme observations are independent. The Anderson Darling test with null hypothesis assumes that the extreme observation follows GPD. This test was employed using R software with command "gpdAd(y)" from EVA package. The observation in all locations follows GPD as P-values are larger than Type-I error $\alpha = 5\%$. The next step is estimating the scale and shape parameter by means of MLE. The results are summarized in Table 2.

TABLE 2. ESTIMATES OF PARAMETERS

LOCATIONS	Scale	Shape
BABAT	17.092	-0.120
BLAWI	23.370	-0.018
KARANGBINANGUN	27.025	-0.169
KEDUNGPRING	19.118	-0.034
LAMONGAN	17.955	-0.100
PANGKATREJO	20.205	-0.196
SUKODADI	14.010	-0.014

Once the parameters estimators were obtained, the next step is applying BHM (in this work using openBugs software) to the data. The conditional prior is updated by involving the location information as follows:

$$p_2\left(\boldsymbol{\theta}_1 \middle| \boldsymbol{\theta}_2\right) = \phi_s \sim MVN\left(\boldsymbol{\mu}_\phi, \boldsymbol{\Sigma}_\phi\right) \tag{12}$$

$$\mu_\phi = \alpha_0 + \alpha_1 lat_s + \alpha_2 long_s \tag{13}$$

$$\Sigma_\phi = \beta_1 \exp(-\beta_2 \left|s - s'\right|) \tag{14}$$

The mean μ_ϕ accommodate the location coordinate represented by latitude and longitude whereas the variance-covariance matrix is accommodate the distances among locations. The equation (13) and (14) are the mean and variance of the process layer (12) to find the posterior distribution in(11). Figure 5 shows the posterior density of scale parameters.

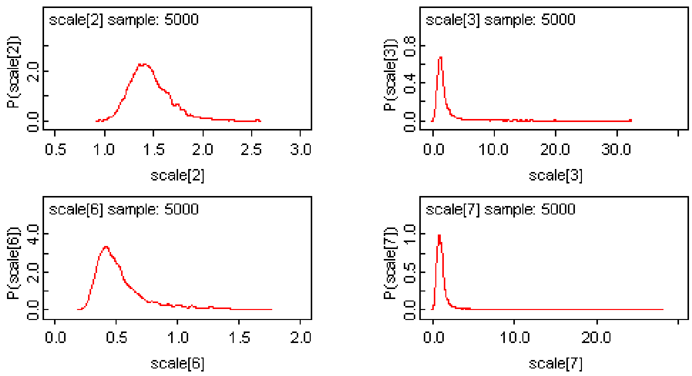


FIGURE 5. POSTERIOR DENSITY OF SCALE PARAMETERS

TABLE 3. PARAMETERS ESTIMATOR OBTAINED FROM BHM APPROACH

Param.	mean	Sd	MC_error	val2.5pc	median	val97.5pc	Start	sample
Beta1	2.185	7.399	0.37	0.08841	0.6363	17.42	4341	5000
Beta2	1.284	0.4611	0.01218	0.2938	1.362	1.924	4341	5000
alpha0	-0.7119	5.03	0.4109	-16.95	-0.009851	5.896	4341	5000
alpha1	-0.01985	0.1014	0.00651	-0.2826	-0.003282	0.1807	4341	5000
alpha2	-0.4897	1.681	0.1124	-5.003	-0.1136	2.147	4341	5000
scale[1]	1.37	0.2343	0.005997	1.016	1.335	1.908	4341	5000
scale[2]	1.458	0.1931	0.004915	1.144	1.434	1.897	4341	5000
scale[3]	1.674	1.434	0.03363	0.4144	1.35	4.921	4341	5000
scale[4]	0.9598	0.2706	0.006348	0.5739	0.9183	1.604	4341	5000

scale[5]	1.512	1.822	0.03425	0.3728	1.263	3.96	4341	5000
scale[6]	0.524	0.2047	0.01077	0.2936	0.4703	1.12	4341	5000
scale[7]	1.016	0.7888	0.01229	0.2457	0.8921	2.662	4341	5000

Table 3 shows that the parameters α_0, α_1 and α_2 are not significant because there is zero value within credible interval while the others are significant. The significant parameters can be used in the model. Thus, it can be concluded that the latitude and longitude variable are suitable for spatial models but not suitable as an effect of predictor models. The model of layer process with μ_ϕ equal to zero is expressed in (15):

$$p_2\left(\boldsymbol{\theta_1}\middle|\boldsymbol{\theta_2}\right) = \phi_S \sim MVN\left(0, \boldsymbol{\Sigma}_\phi\right) \tag{15}$$

Having obtained a significant model, the next step is to estimate the scale and shape parameter as reported in Table 4.

TABLE 4. ESTIMATOR OF SCALE PARAMETERS AND RETURN LEVEL OBTAINED FROM BHM APPROACH

LOCATIONS	n (x>u)	u	scale	Shape	Pr(X>u)	Return Level (Years) 5	20	30	40	100
BABAT	51	85	24.013	-0.20	0.01	130.29	148.50	152.95	155.89	164.22
BLAWI	87	60	14.635	-0.20	0.01	92.24	102.23	104.66	106.28	110.84
KARANGBINANGUN	21	80	19.678	-0.20	0.00	105.17	122.96	127.31	130.18	138.33
KEDUNGPRING	45	72	34.463	-0.20	0.01	134.26	161.06	167.60	171.93	184.19
LAMONGAN	33	67	14.398	-0.20	0.00	90.06	101.96	104.87	106.79	112.24
PANGKATREJO	50	65	13.537	-0.20	0.01	90.36	100.67	103.18	104.85	109.57
SUKODADI	45	68	18.509	-0.20	0.01	101.44	115.83	119.34	121.67	128.25

The predictions of return level for 5, 20, 30, 40 and 100 years were summarized in Table 4. In 2018 (five years return level), the predicted heaviest rainfall daily in Babat Station is 130.29 mm. The return level increased for twenty years become 148.50 mm continuously increased for longer periods. This also happened in other six locations.

IV. CONCLUSION AND SUGGESTIONS

This paper showed the procedure for obtaining estimates of GPD parameters and calculating the return level using a Bayesian Hierarchical models applied to rainfall data in Lamongan. The location information represented by longitude and latitude variable were considered as an input variable in the model. The empirical result shows that these two variables are not significant in the mean model. The return level got higher for longer periods in all stations. These empirical findings suggest that the future research should explore other climatology variables as input in the model.

ACKNOWLEDGMENT

The authors would like to thank BMKG Surabaya for giving permission to use the data employed in this paper.

Abstract**—** Observational studies are the basis of epidemiological research to draw the conclusions of the effects or a response treatment. In general, a randomized trial is required in order to meet the assumption of independence to minimize the bias effects. However in an observational study, particularly in medical field, randomization not able to implement because conduces in doubtful treatment effects estimation. Propensity score is the conditional probability to get certain treatments involving the observed covariates. This method is used to reduce bias in the estimation of the impact of treatment on observational data for their confounding factors. If treatment is binary, then the logistic regression model is one estimated of propensity score because of easiness in terms of estimation and interpretation. In the analysis of observational studies, propensity score stratification (PSS) has proven to be one of methods to adjust the unbalanced covariate for the purposes of causal inference. The data used in this study is the medical records of patients DM in X hospital about the factors that influence the type of diabetes mellitus. In this study PSS used in diabetes mellitus cases to reduce bias due to confounding factors, so that can be known the factors affect the type of diabetes mellitus with obesity as confounding factors. The results of PSS analysis is known that the variables directly influence the type of DM are obesity, age, gender and variable does not directly influence the type of DM are genetic variable, sport activities and dietary habit of patients DM.

I. INTRODUCTION

The attention of non-communicable diseases is increasing currently. From ten leading causes of death, two of them are non-communicable diseases. Diabetes mellitus (DM) is a non-communicable disease with high prevalence. International Diabetes Federation (IDF) stated that people with diabetes mellitus figure reached 382 million people of the world in 2013. It is estimated as 592 million in 2035. In Indonesia, people with diabetes mellitus has reached 8.4 million in 2000 and is estimated to be approximately 21.3 million in 2030. Because of high number of patients, it makes Indonesia ranks fourth after the United States, India and China [1].

According to the results of Indonesia Basic Health Research (RISKESDAS) in 2013, an increase in the prevalence of Indonesia's diabetes mellitus in 2007 was 1.1% to 2.1% in 2013. The results of the analysis of the Diabetes Mellitus prevalence's picture based on a doctor's diagnosis and symptoms increase with age. It began with age $\geq$ 65 years old of decline. The prevalence of diabetes in women is 1.7% while men have 1.4%. Based on its territory, the prevalence of urban areas (2.0%) is higher than in rural areas 1.0% [2].

Diabetes mellitus (DM) is a chronic metabolic disorder due to the pancreas does not produce enough insulin or the body can not use the insulin that is produced effectively. Insulin is a hormone that regulates blood glucose levels. Diabetes mellitus is classified into type 1 diabetes, which is known as insulin-dependent or childhood-onset diabetes, characterized by a lack of insulin production. Type 2 diabetes, known as non-insulin-dependent or adult-onset diabetes, caused by the body's inability to use insulin effectively which then lead to overweight and lack of physical activity [3].

Increasing the number of people with diabetes are mostly caused by the interaction between the factors of genetic susceptibility and exposure to the environment, such as changes in lifestyle and physical activity often leading to obesity. It is a risk factor for the onset of DM [4]. Therefore, diabetes mellitus type 2 is often also called diabetic lifestyle for causes not only because of heredity, but also environmental factors include age, obesity, insulin resistance, food, physical activity, and unhealthy play roles in the occurrence of diabetes [5].

Research on the incidence of diabetes mellitus (DM) has been done in large quantities. For example Wicaksono [4] investigated the factors associated with the occurrence of diabetes mellitus (DM) type II using descriptive analysis and logistic regression. Trisnawati et al. [6] studied the risk factors of type 2 DM outpatients using the McNemar test and logistic regression and Indriyani et al. [7] studied the effect of physical exercise to decreased levels of blood sugar of patients with type 2 DM using the t test with the one group pretest-posttest study design.

The above researches mostly used descriptive analysis and logistic regression without considering the possibility of a powerful combination of factors affecting diabetes mellitus (DM). In fact, as explained previously that the combination of these factors led to the existence of confounding variables that lead to obtain inaccurate conclusions.

Some previous studies have tried to discuss confounding factors randomly, but in the case of health sector, it can not be done. But how the confounding variables included in the factors studied. Therefore, we need a method that can handle the effects of bias caused by these confounding factors. One method that can handle confounding is the propensity score method. it was first introduced by Rosenbaum and Rubin in 1983. The propensity score is defined as the conditional probability to receive interventions based on those characteristics before the intervention [8]. This method is a statistical adjustment that can be used to analyze data from non-experimental research design where design giving treatment through randomization to treatment or control group is not possible. Researchers can use the propensity score for statistical balance or equalize the group of research subjects to reduce bias due to the provision of treatment which is not random.

One method of propensity score that is proven to reduce bias due to confounding effects is the propensity score stratification method. This method focuses on the division of classes / strata based on the estimated value of propensity score. The division of classes / strata aims to balance the distribution between treatment and control groups so that estimate of average treatment effect more accurate.

Several studies of the model used to estimate the value of propensity score, they are McCaffrey et al.[9] which used a model of generalized boosted, McCandless et al. [10] used Bayesian, and Littnerova et al.[11] used logistic regression to estimate propensity score. Of all the study, estimated by logistic regression simpler and easier in interpretation, particular to the category data used.

Based on the description above, the aim of research in this study are to get an estimation of average treatment effect and binary logistic regression model based on the propensity score that shows the factors affecting the type of DM in patients treated in X hospital district after being controlled by confounding variables of obese patients' status.

II. THEORY

2.1 Logistic Regression Model

According to Hosmer & Lemeshow [12] binary logistic model is the logarithm of odds ratio of occurrence of success (π) and probability of occurrence of fail ($1 - \pi$) . The specific form of the logistic regression model with *p* predictor variables expressed in equation (2.1)

$$\pi(\mathbf{x}) = \frac{\exp\left(\beta_0 + \sum_{m=1}^{p} \beta_m x_m\right)}{1 + \exp\left(\beta_0 + \sum_{m=1}^{p} \beta_m x_m\right)} \tag{2.1}$$

Form of simplification of the equation above, then used a logit transformation of the form below.

$$g(\mathbf{x}) = \ln\left(\frac{\pi(\mathbf{x})}{1-\pi(\mathbf{x})}\right) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_p x_p = \mathbf{x}^T \boldsymbol{\beta} \tag{2.2}$$

with $\pi(\mathbf{x})$ is the probability of success, $1-\pi(\mathbf{x})$ is probability of fail event, β_m are the parameters of the linear function with the predictor variables $m = 1, 2, \ldots, p$.

2.2 Propensity Score

Propensity score analysis introduced by Rosenbaum and Rubin 1983 in the journal entitled "The central role of the propensity score in observational studies for causal effects". Propensity score analysis is a statistical method that rapidly evolving innovative and useful for evaluating treatment effects when using observational data [13]. Rosenbaum and Rubin [8] define the propensity score for observation i (i = 1, ..., n) as the conditional probability of a specific treatment (Z_i = 1) versus non-treatment (Z_i = 0) based on the characteristics of the covariates $\mathbf{x}_i$ observed.

According to Guo & Fraser [13] the value of propensity score is defined as follows.

$$e(\mathbf{x}_i) = P(Z_i = 1 \mid X_i = x_i) \tag{2.3}$$

According to Littnerova et al.[11] propensity score using a logistic regression model, the response variable is a binary where to treatment and to the control unit with the following model.

$$e(\mathbf{x}_i) = \mathrm{P}\left(Z_i = 1 \middle| X_i = x_i\right) = \frac{\exp\left(\beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \cdots + \beta_p x_{ip}\right)}{1 + \exp\left(\beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \cdots + \beta_p x_{ip}\right)} \tag{2.4}$$

with β_0 is a constant, $\beta_1, \beta_2, \cdots, \beta_p$ the regression coefficients and $x_1, x_2, \cdots, x_p$ are covariate variables.

According to Cochran & Rubin (1973) in the Pan & Bai [14] measures the bias is reduced for each covariate can use equation (2.11)

$$PBR = \frac{B_{\text{before PS}} - B_{\text{after PS}}}{B_{\text{before PS}}} \text{x}100\% \tag{2.5}$$

and

$$B = p_1(x_p) - p_0(x_p) \tag{2.6}$$

with PBR is Percent Bias Reduction, B is an average difference of the treatment group and the control group for each covariate , $p_1(x_p)$ and $p_0(x_p)$ are proportion of covariates for the treatment group and the control group, $B_{\text{before PS}}$ and $B_{\text{after PS}}$ are represents the difference between the average treatment and control group before propensity score and after propensity score.

2.3 Propensity Score Stratification

Propensity Score Stratification (PSS) is a procedure of classifying subjects into classes based on the estimated propensity score . Subjects are sorted by the estimated propensity score (Austin, 2011). Cochrane (1968) showed that the five sub-class is enough to reduce 90 % of bias with a single covariate [15]. Imbens [16] declared the entire bias under unconfounded associated with the propensity score, it indicates that under the normality used 5 strata change is largely biased with all covariates.

According to Yanovitzky, Zanutto, and Hornik [17] general steps of propensity score analysis are described as follows

1. Choose a covariate as a confounder for the estimation of propensity score. The election process can confounder based on theory and empirical evidence about the relationship between variables.
2. Estimated value of propensity score.
3. Divide the strata based on the propensity score.
4. Check the balance of covariates between the treatment group and the non-treatment.
5. Calculate the effect of confounders.

One way to assess the quality of the propensity score stratification by comparing a variety of statistics such as mean, median, variance, t-test statistics, chi-square test or Kolmogorov-Smirnov (KS) test on each covariate [15]. In this study, KS and chi-square used for testing difference distribution between the treatment group and the control group.

2.4 *Diabetes Mellitus*

Diabetes mellitus is metabolic diseases which is a collection of symptoms that arise in a person because increase in blood glucose levels above normal values . The disease is caused by disorders of the metabolism of glucose due to a deficiency of insulin both absolute and relative terms . There are two types of diabetes mellitus. The first type of DM is type 1, that usually acquired since childhood and results from the pancreas failure to produce enough insulin. The second type of DM is type 2, that usually acquired an adult and condition in which cells fail to respond to insulin. According Poretsky [18] factors that affect type 1 diabetes is a genetic, autoimmune, age, race and ethnicity, gender, and environmental factors such as viral infections, diet / nutrition, stress. In addition, according Gungor, Hannon, Libman, Bacha, & Arslanian [19] factors affecting the type 2 diabetes are genetic, age, gender and environmental factors such as diet, obesity, sports activities.

III. METHODOLOGY

The method used in this study is propensity score stratification (PSS) method to find the factors that influence the type of diabetes mellitus (DM) with obesity status of patients as a confounding factor. The data used is secondary data from medical records of patients (DM) at Hospital X in 2013. The number of respondents are 497 patients. The Patients consist of patients with type 1 of DM (42 patients) and patients with type 2 DM (455 patients). The response variable is the type of DM and predictor variables are genetic, age, gender, dietary habit, sport activities and obesity. The stages of research process can be seen in Figure 1 below.

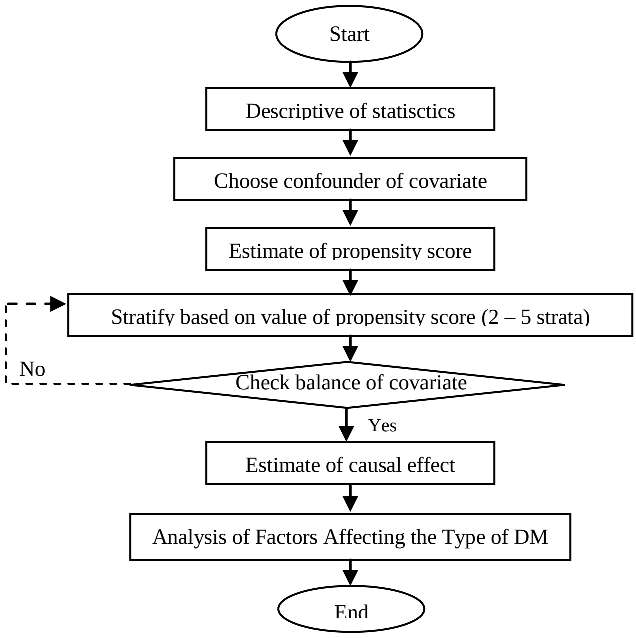

FIGURE 1. STAGES OF RESEARCH PROCESS

IV. RESULT AND DISCUSSION

4.1 Descriptive of Statistics

Descriptive of statistics is an early stage of data exploration to get a general overview of the research data. Characteristics of respondents can be seen from the descriptive of each variables shown in Table 2.

TABLE 1. DESCRIPTIVE ANALYSIS OF COVARIATE

Covariate	**Status Obesity**		**%**	**Type of DM**		**%**
	Obesity	**No Obesity**		**Type 1**	**Type 2**	
Genetic						
- Have genetic	379	31	82,49	0	410	82,49
- Have not genetic	52	35	27,51	42	45	27,51
Age	431	66	-	42	455	-
Gender						
- Male	192	32	45,07	24	200	45,07
- Female	239	34	54,93	18	255	54,93
Dietary habit						

- Meet	29	63	18,51	25	67	18,51
- No Meet	402	3	81,49	17	388	81,49
Sport Activities						
- Active	29	65	18,91	27	67	18,91
- Less Active	402	1	81,09	15	388	81,09

Based on the table 2 can be shown that to 82.49 % patients have genetics DM, 81.49 % patients have dietary habit (no meet) and 81.09 % patients less active in sports activities. In addition, it was known that the number of female patients (54.93%) are greater than male patients (45.07 %). From table 2 can shown too that the most patients have obesity and type 2 diabetes are genetics diabetes, female gender, dietary habit (no meet) and patients who has less active exercise in sport activities.

4.2 Propensity Score Stratification Analysis

4.2.1 Choose a covariate as a confounder

The first step in the propensity score analysis is to choose covariate as a confounder variable. The determination of confounding variables based on the theory and proven with empirical evidence like the relationship between variables. Testing relationship between variables used chi-square test. Based on research conducted by Betteng, et al.[5] known that obesity has a relationship with genetic factors, dysfunction of the brain, dietary habit is over, less activities of sport, emotional, environmental factors, social factors and lifestyle. Therefore, this relationship will be proven by empirical evidence using chi-square test . Results of testing the correlation between covariates with obesity variables are shown in Table 2.

TABLE 2. TESTING RESULTS CORRELATION BETWEEN COVARIATES WITH OBESITY

Variable	χ^2	Df	P-*value*	Decision
$x_4 * x_1$	66,513	1	0,000	Reject H_0
$x_4 * x_2$	2,047	3	0,563	Failed to reject H_0
$x_4 * x_3$	0,358	1	0,549	Failed to reject H_0
$x_4 * x_5$	298,701	1	0,000	Reject H_0
$x_4 * x_6$	314,208	1	0,000	Reject H_0

Based on Table 2 can be shown that genetic, diet and active sports activities has significant influence to obesity variables. Meanwhile age and gender has not significant influence to obesity. Based on those results, so it is a proof that obesity variable is the most variable that associated with other variables. Therefore, obesity variable is selected as confounding variable Z with parameter θ.

4.2.2 Estimating the Propensity Scores

In this study the propensity score estimated by logistic regression. There are five variables will be estimated, their variables are genetic, age, gender, dietary habit and sports activities. The result of parameter is shown in Table 3.

TABLE 3. PARAMETER ESTIMATION FOR THE RELATIONSHIP OBESITY (Z) WITH COVARIAT (X)

Covariate	Parameter (β)	SE	p-value	OR	OR (95% CI)
Intercept	3.8357	1.4479	0.0081	33.9019	1.4069 - 16.8948
Genetic	2.3211	0.6562	0.0004**	10.7902	2.9338 - 39.6853
Age	0.0118	0.0192	0.5397	1.0174	0.9706 - 1.0665
Gender	0.1722	0.4500	0.7020	0.9835	0.3872 - 2.4980
Dietary habit	-1.8721	1.3741	0.1731*	0.1682	0.0114 - 2.49269
Sport Activities	-5.2426	1.6029	0.0011**	0.0057	0.0002 - 0.1328

(*) significant at α = 20%, (*) significant at α = 0,1%,

Based on Table 3 can be shown that the variables have significant influence to obesity at significance level (α = 0.1 %) are variable genetic with p-value = 0.000 and sport activities with p-value = 0.0011, while dietary habit variable is significance at α = 20%. It is indicates that the status of obesity patients DM was determined by genetic factors, dietary habit, and sports activities of patient DM.

From the estimation parameters are shown in Table 3, it can be obtained the value of propensity score below.

$$e(\mathbf{x}_i) = \frac{\exp\left(3,84 + 2,32\, Gen(1) + 0,01\, Age + 0,17\, Gndr(1) - 1,87\, DH(1) - 5,24\, SA(1)\right)}{1 + \exp\left(3,84 + 2,32\, Gen(1) + 0,01\, Age + 0,17\, Gndr(1) - 1,87\, DH(1) - 5,24\, SA(1)\right)} \qquad (2.7)$$

Equation (2.7) illustrates that each age of patients DM is increase one year, so the odds of obesity will increase by 1,017 times. The probability of someone who have genetic DM become obesity is 10.79 times greater than someone who does not have a genetic history of diabetes, the probability of a women having obesity is 0.984 times greater than a men , the probability of someone a healthy diet having obesity is 0,168 times than someone whose diets are not healthy and active sports person's probabilitys having obesity is 0.006 times that of someone who rarely exercise.

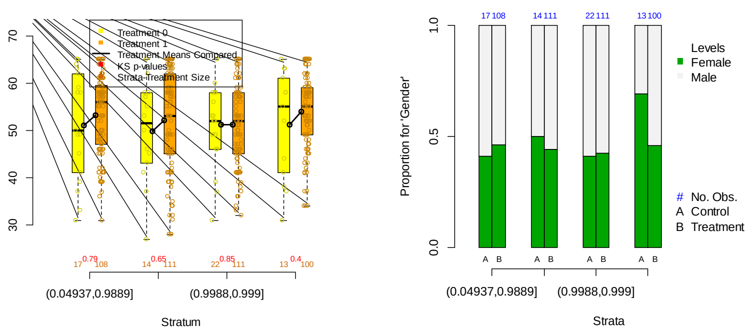
4.2.3 Stratify and Balance the Propensity Scores

After estimating the propensity scores, the next step is subclassified them into different strata. The formation of this stratum aims to balance the treatment and control groups so that estimates of treatment effect is not biased. The number of balanced propensity score strata depends on the number of observations in the data set. Table 4 shows the test of covariate balance after stratification based on the quintiles of the propensity score. Five of the covariates were included in the final propensity score model used for stratification. The initial imbalances were measured by chi-square test for categorical data (genetic, gender, dietary habit and sport activities) and Kolmogorov-Smirnov test for continuous data (age) comparing the obesity and no obesity groups.

TABLE 4. TEST OF STRATA BALANCE

Strata	**n**	**Chi-Square Tests for Balance**				**KS-Test for Balance**
		Genetic	**Gender**	**Dietary Habit**	**Sport Activities**	**Age**
1	126	0,058	0,800	0,954	0,525	0,790
2	125	0,052	0,780	0,525	1,000	0,650
3	133	0,055	1,000	1,000	0,475	0,850
4	113	0,062	0,150	1,000	1,000	0,400

Based on Table 4 can be shown that after testing using chi-square test for categorical data, their covariates such as genetic, gender, dietary habit and sports activities shows that obesity and no obesity have a balance at all strata. Similarly, for the covariates of age which was tested by Kolmogorov-Smirnov (KS) test. Covariate testing balance is supported by Figure 2. Figure 2 represents a picture which shows a balance between the obesity and no obesity for categorical data (gender) and continuous data (age). So that the analysis can be continued to the next step, the step is estimate average treatment effect or average effect of obesity on the type of DM. Pattern of balance can be seen in Figure 2 below.



(A) (B)

FIGURE 2. COVARIATE OF PROPENSITY SCORE IN BALANCE STRATA (A) AGE, (B) GENDER

4.2.4 Estimating the Causal Effect

Propensity score is an ideal method to see the effect of treatment on observational studies. This method can reduce bias effect because differences distribution of covariate between treatment and control groups. Therefore, before the estimated treatment effects, covariates between the treatment and control groups should be balanced. Because in the previous step has been obtained strata with covariates were balanced, then the next step is estimation of the treatment effect. In this case estimate of the effect of obesity on the type of DM. The estimation results for before and after stratification shown in Table 5.

TABLE 5. RESULT OF ESTIMATION AVERAGE TREATMENT EFFECT (ATE)

ODD RATIO FOR ATE					
BEFORE STRATIFICATION			AFTER STRATIFICATION		
UNADJUSTED	SE UNADJUSTED	95% CI STRATA	ADJUSTED	SE ADJUSTED	95% CI STRATA
16,859	0,3583	8,353 – 34,027	7,065	0,516	2,570 – 19,424

Table 5 shows the result for estimated effect of obesity on the type of DM before and after stratification. From table 5 obtained an average yield effects of obesity on the type of DM before stratification (unadjusted) is 16.859 with a standard error of 0.3585 and after stratification (adjusted) the effect of obesity is 7.065 with the standard error of 0.516. Propensity method also provides estimates of 95% confidence interval between 2.570 and 19.424. This confidence interval shown the difference average between the treatment group and the control of obesity is significant, or in other words, obesity significantly influence the type of DM with the effect is 7.065.

4.3 Analysis of Factors Affecting the Type of DM

After the estimation of treatment effects (obesity) was known then the next step is to determine the relationship of covariates with type of DM.

TABLE 6. PARAMETER ESTIMATION FOR THE RELATIONSHIP BETWEEN TYPE OF DM (Y) WITH COVARIAT (X)

Covariate	Parameter $\left(\boldsymbol{\beta}^*\right)$	SE	p-value	OR	OR (95% CI)
Intercept	2.8368	1.4367	0.0483	17.0611	1.0211 – 285,0692
Genetic (1)	21.2478	1375.7492	0.9877	1689671554	-
Age	-0.0448	0.0277	0.1059*	0.9562	0,9056 – 1,0095
Gender(1)	0.7892	0.5213	0.1301*	2.2016	0,7925 – 6,1162
Dietary habit(1)	-0.5024	1.3191	0.7033	0.6051	0,0456 – 8,0288
Sport Activities(1)	-1.3926	1.2916	0.2810	0.2484	0,0198 – 3,1234

(*) significant at $\alpha = 20\%$

Based on Table 6 can be shown that the variables significantly influence to the type of DM at significance level α = 20 % are variable age with *p*-value = 0.106 and gender with *p*-value = 0.1301. Based on the table 6 known that the type of DM patients was influenced by the age and gender of patients DM, or age and gender variable are variables that directly influence the type of DM patients.

From the estimation parameters are shown in Table 6, can be obtained logistic regression model covariates significant relationship between the type of DM as below.

$$\pi\left(\mathbf{x}_i\right)=\frac{\exp\left(2,837-0,045\,Age+0,789\,Gender\left(1\right)\right)}{1+\exp\left(2,837-0,045\,Age+0,789\,Gender\left(1\right)\right)} \tag{2.8}$$

Equation (2.8) illustrates that any increase 1 year of age patients DM, the odds for type of DM decreased by 0.956 times and the probability for women having type 2 of DM is 2,202 times greater than men.

V. CONCLUSSION

Propensity score is a good method to see the effect of treatment on observational studies, particularly data with different background covariates. The different of covariate can make inaccurate conclusions. Propensity score stratification can balance the covariates between the treatment and control groups so that can reduce bias due to confounding effects. Analysis of propensity score stratification shown that the variables influence obesity are genetic variable, sports activities and dietary habit of patients and the effect of obesity on the type of DM after stratification is amount 7.065 with a standard error of 0.516. In addition, the variables that directly influence the type of DM patients are obesity, age, gender and variable that does not directly affect the type of DM patients are genetic variable, sport activities and dietary habit of patients DM with the obesity as confounding factors if modeled by logistic regression.

Abstract - The paper discussed a parameter estimation methods and construction of spatial weighted matrix in the modeling of the spatial data. Many options can be used to construct a spatial weighted matrix, one of the them is a matrix AMOEBA (W_AMOEBA). Here, we studied about the W_AMOEBA and Contiguity matrix spatial lag model (SLM) using two step least square (two-SLS) . For simulation, we used human development index (HDI) data. The results showed that the relative W_AMOEBA is more accurate than W-contiguity.

Keyword: Spatial modelling, Two-SLS, W_AMOEBA, W_Contiguity.
2010 Mathematics Subject Classification: Primary 62H10 and Secondary 60E05

1. INTRODUCTION

1.1 Background

Many authors have studied about spatial models such as Folmer and Oud (2008), Liu, et.al (2011a, 2011b) and Aldstadt and Getis, 2006. They discussed W-structural equation model (W_SEM) and W-an multidirectional optimum ecotope base algorithm (W_AMOEBA), respectively.

Spatial data is a stochastic process which have more than two indexes. There were researchers have already studied modeling of spatial data in theoretical and application. The objective of spatial data analysis is to determine the pattern of the spatial data. The spatial data are usually dependent each others. It is called spatial autocorrelation. In the model of spatial data, the autocorrelation is represented by spatial weighted matrix.

Human development index (HDI) is one of the indicators for seeing development of regions (area). Here, we face problem on correlation among adjacent areas (neighbored area).. To accommodate dependence among those areas, the spatial weighted matrix is used. Here, there are several ways to construct a spatial weighted matrix such as contiguity, inverse distance contiguity, and *k*-nearest neighbor (Anselin,1995, Stakhovych and Bijmolt, 2008), ***W-SEM*** (Folmer and Oud, 2008, Liu, et.al 2011a, 2011b) and ***W-AMOEBA*** (Aldstadt and Getis, 2006).

1.2. Objectives

The objective of this study is to evaluate of W-AMOEBA and W-contiguity on spatial lag model (SLM) in the case of the HDI.

2. RESEARCH METODOLOGY

2.1 Spatial Lag Model

In linear regression model, spatial dependence can be incorporated in two distinct way: as an additional regression in the form of a spatially lag dependence (***Wy***) or in the error structure. Spatial lag model (SLM) (or spatial autoregressive, SAR) is appropriate when the focus of interest is the assessment of existence and strength of spatial interaction (Anselin, 1995). Generally, a spatial lag model or spatial autoregressive model is given as

$$\boldsymbol{y} = \boldsymbol{\rho W y} + \boldsymbol{X\beta} + \boldsymbol{\varepsilon}, \tag{1}$$

where
$\boldsymbol{y}$ = vector of dependent variable
$\boldsymbol{X}$ = matrix of independent variable
$\boldsymbol{W} =$ spatial weighted matrix
ρ = spatial autoregressive coefficient
$\boldsymbol{\beta}$ = vector of parameter
$\boldsymbol{\varepsilon}$ = vector of error terms

Here, the spatial autoregressive coefficient (ρ) is assumed to stationary when $|\rho| < 1$.

2. 2. W Contiguity

Spatial weighted matrix is an essential component of the spatial model. Generally, spatial weight matrix that used to spatial model based on contiguous area (geographically) and inverse distances. Due to of the geographical proximity, the spatial weighted matrix is created as follows. Let $W = \{w_{ij}\}$ $i, j = 1,2, ..., n$, is contiguities matrix with w_{ij} represents the value of spatial unit i and j, and here we also present spatially located at some positions see Figure 1.

D	***F***	*G*
H	*I*	*J*

Figure 1 Contiguity matrices *rook (b), bishop (c)* and *queen (d)* of spatial unit on (*a*) that close to ***F***.

Inverse distance matrix is another type of spatial weighted matrix that often used in spatial modeling. Generally, type of distance that use in constructing spatial weight matrix is the Euclidean distance. For two coordinate spatial units i and j, (x_i, y_i) *and* (x_j, y_j), the inverse distance is expressed as

$$W_{ij}=\{1/d_{ij}\}, \text{ where } d_{ij} = \sqrt{\left(x_i - x_j\right)^2 + \left(x_i - x_j\right)^2}.$$

2.3 W_AMOEBA

A multidirectional optimum ecotope-based algorithm (AMOEBA) is one of an illustration on the spatial weighted matrix. The AMOEBA is usually depended on the behavior data. Furthermore, W_AMOEBA are designed to clustering spatial units and construct spatial weighted matrix on empirical data (Alsdstadt and Getis, 2006). Later, the W_AMOEBA is defined as combination between the geographic and behavior data (Stakhovych and Bijmolt 2008; Alsdstadt and Getis, 2006). Here, the W_AMOBA has a special procedure that developed by Aldstadt and Getis (2004). Note that in the W_AMOEBA, the local Getis statistic is used to divide into high and low spatial units.

Let an area is divided for n regions, i=1,2,...,n, $G_i = \frac{\sum_{j \neq i} w_{ij} x_j}{\sum_{j \neq i} x_j}$ is local Getis statistic, and $G_i^* = \frac{G_i - E(G_i)}{\sqrt{VarG_i}}$ be standard local Getis statistic. Let $G_i^*(k)$ is the value of statistics G_i^* for link k, The AMOEBA algorithm (Altstadt and Getis, 2006) is given as follows.

At the outset of the AMOEBA procedure, we compute $G_i^*(0)$, here the ecotope consist of just the i^{th} unit ($k = 0$). The value of $G_i^*(0)$ is greater than zero, it indicates that the value at location i is larger than mean of all unit, and otherwise. For k=1, $G_i^*(1)$, this value shows that for each areas/region that contains units i and all combinations of its contiguous are neighbors. If $G_i^*(0)$ is greater than the combination that maximizes $G_i^*(1)$, it be new high ecotope. If $G_i^*(0)$ is less than the combination that maximizes $G_i^*(1)$, it be new low ecotope. At each succeeding step, for the contiguous units include in the ecotope, they are then not considered. Likewise, units included in the ecotope remain in the ecotope. Subsequent steps evaluate all combinations of contiguous neighbors and new members of the ecotope are then identified. This process continues for *k*, *k = 2, 3, ..., max.* The final ecotope (k_{max}) is identified when the addition of any set of contiguous units fail to increase the absolute value of the statistics G^*_i. The results of the AMOEBA procedure are then used to construct ***W*** using several steps as follow

.

(a) when $k_{maks} > 1$,

$W_{ij} =$

$$w_{ij} = \begin{cases} \dfrac{\{P[z \le G_i^*(k_{maks})] - P[z \le G_i^*(k_j)]\}}{\{P[z \le G_i^*(k_{maks})] - P[z \le G_i^*(0)]\}}, 0 < k_j \\ 0 \qquad , \quad \text{untuk } k_j \text{ se} \end{cases}$$

0 , otherwise

(b) when $k_{max} = 1$, $w_{ij} = 1$ for $k_j=1$ and 0 otherwise.

(c) When $k_{max} = 0$, $w_{ij} = 0$ for all k

where k_j is *link* that connecting between *i* and *j* in ecotope.

2.4. Instruments Variables Method

The simple method of estimation parameter in regression models is ordinary least square (OLS). One of the advantages of the OLS is robust to error distribution. Here, the error and exogenous variable must be independent. If the model containing endogenous variable and residual distribution is not known, we need other estimation methods, one of them is the method of instrumental variables of two step least square (two-SLS) (Verbeek, 2008).

We see that SLM contains endogenous variable (***Wy***), so the OLS can't be used to estimate model parameters. To overcome this problem, we must used other method. Instrument variable method or two-stage method is one of methods that can be used to solve endogenous problem in spatial model. The principle of the instrument variable method is to use new variable that correlated to the response variable, but uncorrelated with the residual.

3. RESULTS

3.1 Violation OLS on SLM

Let $Z = (\boldsymbol{Wy}\ \ \boldsymbol{X})$, and $\boldsymbol{\theta} = \begin{pmatrix} \rho \\ \boldsymbol{\beta} \end{pmatrix}$, so the SLM model can be written as

$$\boldsymbol{y} = \boldsymbol{Z\theta} + \boldsymbol{\varepsilon}, \tag{2}$$

where the assumptions of the OLS method are $\boldsymbol{E(Z'\varepsilon)} = 0$ and Cov(.$\boldsymbol{\varepsilon, Z}) = \boldsymbol{0}$. Due to Z consists of *Wy* and *X* variables, so the OLS is fail to estimate parameter model on the SLM. This is due to the assumption is violate.

The assumption of the OLS $\boldsymbol{E(Z'\varepsilon)} = 0,$ we then have $\boldsymbol{E(W'\varepsilon)} = 0$ and $\boldsymbol{E(X'\varepsilon)} = 0$.

Here,

$$\boldsymbol{Cov(\varepsilon, Wy)} = \boldsymbol{Cov(\varepsilon, W(\rho Wy + X\beta + \varepsilon))}$$

where Cov $(\varepsilon, Wy) \neq 0$ because Wy = W(y+Xβ+ε) = Wy+WXβ+Wε), so Cov (ε,Wy)=Cov(ε, Wy+WXβ+Wε) $\neq 0$. Therefore the moment, i.e $\boldsymbol{E(Z'\varepsilon)} = 0$, is violate.

ISBN 978-602-74529-0-9

3.2 Method of Variable Instrument

The method of variable instrument (*IV*) is also called a two-stage OLS method. In this method, the endogenous variable is instrumented by new variables, but in SLM method, the endogenous variable, ***Wy,*** is instrumented with new variable that correlated to response, but uncorrelated to the error terms.

Due to SLM model, let, $Z = (\boldsymbol{Wy}\ \ \boldsymbol{X})$ and $\boldsymbol{\theta} = \begin{pmatrix} \rho \\ \boldsymbol{\beta} \end{pmatrix}$, so (1) can be expressed as (2). To estimate parameter $\boldsymbol{\theta}$, we use ***IV method*** as follows:

(1) determine instrument variable **H**,

$$E(\boldsymbol{\varepsilon} \mid \mathbf{H}) = 0, Cov(\mathbf{Z}, \mathbf{H}) \neq 0$$

$$\mathbf{H} = \begin{bmatrix} \mathbf{X} & \mathbf{WX} & \mathbf{W}^2\mathbf{X} & \cdots \end{bmatrix},$$

(2) estimate **Z** using variable **H**, $\hat{\mathbf{Z}} = \mathbf{H}(\mathbf{H}'\mathbf{H})^{-1}\mathbf{H}'\mathbf{Z}$ as follow

$$\hat{\theta} = (\hat{\mathbf{Z}}'\mathbf{Z})^{-1}\hat{\mathbf{Z}}'\mathbf{y},$$

$$Var(\hat{\theta}) = \hat{\sigma}^2(\hat{\mathbf{Z}}'\mathbf{Z})^{-1}$$

$$\hat{\sigma}^2 = \hat{\boldsymbol{\varepsilon}}'\hat{\boldsymbol{\varepsilon}} / n,$$

$$= (\mathbf{y} - \mathbf{Z}\hat{\theta})'(\mathbf{y} - \mathbf{Z}\hat{\theta}) / n$$

3.3 Performance Investigation of W-Contiguity and W AMOEBA with HDI Data

To evaluate the spatial weighted matrix W_AMOEBA (WG) and W_Contiguity (WC), we used the HDI data of the central of Java (Jateng). Here, we assumed that the HDI between districts have spatial relationships. HDI data is from SUSENAS 2013 BPS JATENG (2014) with single response and four predictors, namely (1) *Y = human development index (HDI), (2)* X_1 *= the average length of school, (3)* X_2 *= overcrowding, (4)* X_3 *= the number of physicians per health center, and (5)* X_4 *= income per capita*

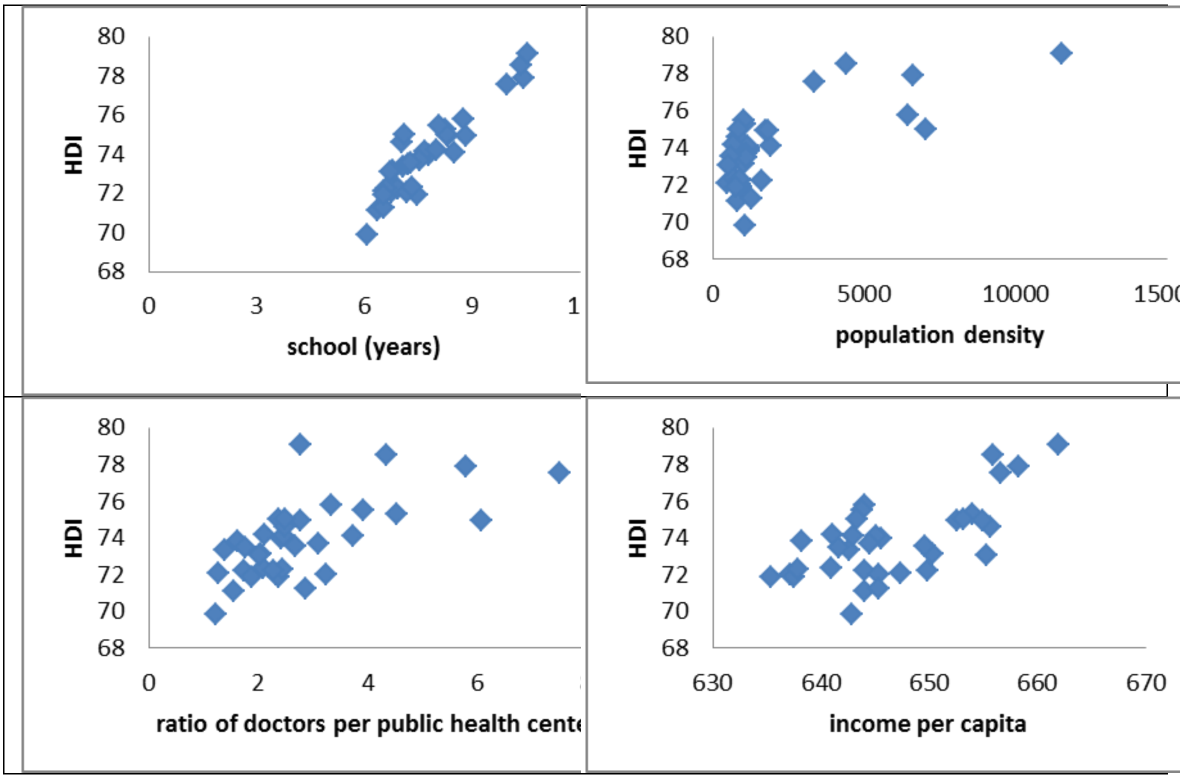

Figure 2. Scatterplot of response variable versus predictors

From Figure 2, we see that relationship between response variable, predictor variables and duration of school factor have significant association to HDI, but not for others factor.

Table 1. ANOVA for SLM model

	WG			WC		
	Est.	Stdev	t.value	Est.	Stdev	t.value
ρ	-0.0060	0.0037	-1.6413	0.1064	0.0977	1.0884
X1	1.9844	0.2501	7.9353	1.8399	0.2417	7.6126
X2	-0.0001	0.0001	-1.8362	-0.0002	0.0001	-1.9517
X3	-0.3844	0.1413	-2.7207	-0.3398	0.1415	-2.4014
X4	0.0932	0.0023	41.2132	0.0821	0.0112	7.3251
R^2		90,0%			89,1%	
RMSE		0.67			0.69	

Table 1 showed that the coefficient R^2 on WG is greater than R^2 on WC. We see also that the root mean square error (RMSE) on WG is less than the RMSE on WC. Finally, we conclude that weighted spatial matrix WG is better than weighted spatial matrix WC.

Prediction of HDI in term of the model with WG and WC are presented Table 2.

Table 2. Predicting values of HDI_WG Y_hat(WG), HDI WC and actual data

4. CONCLUSION

For spatial modeling, the response that has a spatial relationship need weighted spatial matrix for accommodating its relationship. The choice of the spatial weighted matrix should consider the characteristics and behavior of the data and adjacent geographical area. AMOEBA weighted matrix is a significant matrix to improve the accuracy of predicting results.

Abstract—Statistical methods which often used to analyze count data is Poisson regression. However, Poisson regression is not appropriate to be used in analyzing a Zero-inflated count data so that the method used is the Zero-inflated Poisson (ZIP). To model a pair of count data with Poisson distribution and has correlation with some Zero-inflated predictor variable, Bivariate Zero-inflated Poisson Regression (BZIPR) can be used. Therefore, this study was developed in Geographically Weighted Bivariate Zero-inflated Poisson Regression (GWBZIPR). GWBZIP regression parameter estimation was conducted using Maximum Likelihood Estimation (MLE), whereas hypothesis testing was conducted using Maximum Likelihood Ratio Test (MLRT).

Keywords:*Bivariate Poisson Regression, MLE, MLRT, BZIPR, GWBZIPR*

I. INTRODUCTION

Regression analysis is a statistical method that used in various fields, as it provides a simple concept to investigate the functional relationship between the response variable and the predictor variable. If the response consists of positive integers or non-negative valued and stated the number of observations, the response variable is called as a discrete count data [2]. The statistical method used to analyze count data is the Poisson regression [7]. Count data exaggerated with zero value is referred to as Zero-inflated. Zero-inflated can lead to over-dispersion or the mean and variance are not the same [1]. It is therefore not appropriate to use poisson regression in analysing the Zero-inflated count data. Zero-inflated Poisson (ZIP) regression considered as more proper method in dealing with Zero-inflated count data[3]. ZIP regression can be applied to the case of univariate, bivariate and multivariate. Bzipped regression model can produce estimated values of parameters that are global or equal to the entire location. This study developed a Geographically Weighted Bivariate Zero-inflated Poisson Regression (GWBZIPR) model to perform estimation and hypothesis testing using Maximum Likelihood Estimation (MLE) and the determination of the test statistics is using Maximum Likelihood Ratio Test (MLRT).

II. LITERATURE

A. Bivariate Zero-Inflated Poisson Regression

Let Y_1 and Y_2 is a random variable that jointly bivariate Poisson distribution with probability function as follow:

$$f\left(y_1, y_2\right) = \begin{cases} e^{-(\mu_1+\mu_2+\mu_0)} \sum_{k=0}^{\min(y_1,y_2)} \dfrac{\mu_1^{y_1-k}\mu_2^{y_2-k}\mu_0^{k}}{(y_1-k)!(y_2-k)!k!}, & (y_1, y_2) = 0,1,2,... \\ 0 & ,(y_1, y_2)\ others \end{cases} \quad (1)$$

Where the regression equation as follows:

$$(Y_{1i}, Y_{2i}) \sim PB(\mu_{1i}, \mu_{2i}, \mu_0)$$
$$\mu_{ji} + \mu_0 = e^{x_i^T \beta_j} \;\; ; j = 1, 2 \tag{2}$$

Estimation method used in Bivariate Poisson Regression is Maximum Likelihood Estimation (MLE). The method for calculating test statistic onparameter test is Maximum Likelihood Ratio Test (MLRT) :

$$D(\hat{\beta}) = -2\ln\left(\frac{L(\hat{\omega})}{L(\hat{\Omega})}\right) = 2\left(\ln L(\hat{\Omega}) - \ln L(\hat{\omega})\right) \tag{3}$$

where

$L(\hat{\omega})$: Maximum Likelihood for complete model with predictor variable

$L(\hat{\Omega})$: Maximum Likelihood for simple model without predictor variable

B. Generalized Poisson Regression

A pair of count data poisson distribution which has zero value deal on response variables can be analyzed by Bivariate Zero-inflated Poisson Regression. Distribution of Bivariate Zero-inflated Poisson is as follows [6] :

$$f(Y_1, Y_2) = \begin{cases} (1-\pi) + \pi e^{-(\mu_1+\mu_2)}\left(1 + \alpha(1 - e^{-\mu_2 c})\right) & ,(y_1, y_2) = (0,0) \\ \dfrac{\pi e^{-(\mu_1+\mu_2)} \mu_1^{\,y_1} \mu_2^{\,y_2}}{y_1!\, y_2!}\left(1 + \alpha(e^{-y_1} - e^{-\mu_1 c})(e^{-y_2} - e^{-\mu_2 c})\right) & ,(y_1, y_2) \neq (0,0) \end{cases} \tag{4}$$

The regression equation is:

$$\mu_1 = e^{\mathbf{X}^{\mathbf{T}}\boldsymbol{\beta}_1} \text{ dan } \mu_2 = e^{\mathbf{X}^{\mathbf{T}}\boldsymbol{\beta}_2}$$
$$\pi = \frac{e^{\mathbf{X}^{\mathbf{T}}\boldsymbol{\gamma}}}{1 + e^{\mathbf{X}^{\mathbf{T}}\boldsymbol{\gamma}}} \text{ dan } (1-\pi) = \frac{1}{1 + e^{\mathbf{X}^{\mathbf{T}}\boldsymbol{\gamma}}}$$

where $c = 1 - \frac{1}{e}$

C. Corellation Test

Correlation analysis is usually used to measure the linear relationship between the response variable and the predictor variables through a number called the coefficient of correlation. The value of the correlation coefficient ranges between -1 and 1, which shows the relationship of positive and negative. If the correlation value is positive or negative approach of 1 means the two variables have a close relationship. The hypothesis test of correlation between response variable following:

H_0 : there is no relationship between Y_1 and Y_2

H_1 : there is relationship between Y_1 dan Y_2

The test statistic

$$t = \frac{r_{Y_1Y_2}\sqrt{n-2}}{\sqrt{1 - (r_{Y_1Y_2})^2}} \quad \text{where} \quad r_{Y_1Y_2} = \frac{\sum_{i=1}^{n}(y_{1i} - \overline{Y}_1)(y_{2i} - \overline{Y}_2)}{\sqrt{\sum_{i=1}^{n}(y_{1i} - \overline{Y}_1)^2 \sum_{i=1}^{n}(y_{2i} - \overline{Y}_2)^2}}$$

H_0 rejected if $T > t_{\alpha/2}$

D. Multicolinearity Test

Multicollinearity among predictor variables may result inaccurate parameter estimation. Detection of multicollinearity in Poisson regression modeling is very important as correlation between predictor variables with other predictor variables indicate that those two variables have a comparable value. According to [5], the detection of multicollinearity can be done using Variance Inflation Factor (VIF). VIF calculation using the following formula:

$$\text{value } VIF = \frac{1}{1-R_j^{\,2}}$$

E. Spatial Effects

Spatial data on each observation has the characteristics that identify a pair of geographic coordinates or the location of each data covering areas such as agriculture, geology, environmental science and economics [8].Modeling spatial data can be grouped by two types of spatial and spatial point of the area. In modeling the spatial data, spatial weighting matrix is required. Weighting matrix used to represent the scope of information and spatial effects from a location in the system such as geography or the coordinates of latitude and longitude. Spatial heterogeneity between one and other locations indicated by the weighting matrix $W(u_i, v_i)$ whose elements are a function of the Euclidean distance between locations. Form of weighting function of the Euclidean distance use the kernel functions follow,

$$w_{il} = \begin{cases} \left(1-\left(\dfrac{d_{il}}{h_i}\right)^2\right)^2 & \text{, if } d_{il} \le h \\ 0 & \text{, if } d_{il} > h \end{cases}$$

h bandwidth is the radius of a circle where a point located within the radius of the circle considered influential in shaping the parameters of the model location *i*. Determination of the bandwidth will affect the accuracy of the model related to the variance and the bias estimator produced. The optimal bandwidth can be obtained by using the method of Cross Validation (CV) as follows [4]:

$$CV(h) = \sum_{i=1}^{n}\left(y_i - y_{\neq i}(h)\right)^2$$

The identification of spatial heterogeneity is tested using Koenker-Basset.
Hypothesis:

H_0 : no heterogeneity

H_1 : heterogeneity

Statistics test :

$$Z = \frac{\gamma_1}{SE(\gamma_1)}$$

H_0 rejectedif $|Z| > Z_{\alpha/2}$.

F. Geographically Weighted Bivariate Zero-Inflated Poisson Regression (GWBZIPR)

Model GWBZPR is a local form of the Zero-inflated Poisson regression model estimator that will generate local model parameters to each location. GWBZIP distribution is :

$$f(Y_{1j}, Y_{2j}) = \begin{cases} \left((1-\pi_j) + \pi_j e^{-(\mu_{1j}+\mu_{2j})}\left(1+\alpha(1-e^{-\mu_{2j}c})\right)\right) & ,(y_{1j}, y_{2j}) = (0,0) \\ \dfrac{\pi_j e^{-(\mu_{1j}+\mu_{2j})}\mu_{1j}^{\;y_{1j}}\mu_{2j}^{\;y_{2j}}}{y_{1j}!\,y_{2j}!}\left(1+\alpha(e^{-y_{1j}} - e^{-\mu_{1j}c})(e^{-y_{2j}} - e^{-\mu_{2j}c})\right) & ,(y_{1j}, y_{2j}) \neq (0,0) \end{cases} \tag{5}$$

Where

$$\mu_{1j} = e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta}_1(u_i,v_i)} \text{ and } \mu_{2j} = e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta}_2(u_i,v_i)}$$
$$\pi_j = \frac{e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}}{1+e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}} \text{ and } (1-\pi_j) = \frac{1}{1+e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}} \tag{6}$$

III. METHOD

Steps to get parameter estimation of GWBZIPR is to determine the likelihood function based on GWBZIP distribution, form and function of the natural logarithm likelihood. And the find the first derivative function of the natural logarithm likelihood under population and define the equation to be equal to zero. If there is no close form solution, Newton-Raphson iteration method is performed to find out the estimator. To test the hypothesis a maximum likelihood ratio test is performed.

IV. RESULT AND DISCUSSION

GWBZIPR model was developed from BZIPR model which use MLE as a method in estimating parameter and resulting a global parameter estimation applied to all locations. Therefore, the estimation of model parameters GWBZIPR will use the MLE method with the likelihood function as follows:

$$L\left(\alpha, \boldsymbol{\gamma}(u_j,v_j), \boldsymbol{\beta_1}(u_j,v_j), \boldsymbol{\beta_2}(u_j,v_j),\ j=1,2,\ldots,n\right) = \underset{(y_{1j},y_{2j})=(0,0)}{\prod_{j=1}^{n} g_j} + \underset{(y_{1j}y_{2j})\neq(0,0)}{\prod_{j=1}^{n} h_j} \tag{7}$$

Where

$$g_j = \frac{1}{1+e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(\mathbf{u_i},\mathbf{v_i})}} + \frac{e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(\mathbf{u_i},\mathbf{v_i})}}{1+e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(\mathbf{u_i},\mathbf{v_i})}} \exp\left(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(\mathbf{u_i},\mathbf{v_i})} - e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(\mathbf{u_i},\mathbf{v_i})}\right) \begin{bmatrix} 1+\alpha\left(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(\mathbf{u_i},\mathbf{v_i})}c)\right) \\ \left(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(\mathbf{u_i},\mathbf{v_i})}c)\right) \end{bmatrix}$$

$$h_j = (r)(s)$$

$$r = \frac{\dfrac{e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(\mathbf{u_i},\mathbf{v_i})}}{1+e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(\mathbf{u_i},\mathbf{v_i})}} \exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(\mathbf{u_i},\mathbf{v_i})} - e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(\mathbf{u_i},\mathbf{v_i})})(e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(\mathbf{u_i},\mathbf{v_i})})^{y_{1j}}(e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(\mathbf{u_i},\mathbf{v_i})})^{y_{2j}}}{y_{1j}!\,y_{2j}!}$$

$$s = 1+\alpha(e^{-y_{1j}} - \exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(\mathbf{u_i},\mathbf{v_i})}c))(e^{-y_{2j}} - \exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(\mathbf{u_i},\mathbf{v_i})}c))$$

To estimate the parameters $\left(\alpha, \boldsymbol{\gamma}(u_i,v_i), \boldsymbol{\beta}_1(u_i,v_i), \boldsymbol{\beta}_2(u_i,v_i)\right)$ is

$$\ell = \ln L\left(\alpha, \boldsymbol{\gamma}(u_i,v_i), \boldsymbol{\beta}_1(u_i,v_i), \boldsymbol{\beta}_2(u_i,v_i)\right) = \ln \prod_{j=1}^{n} (g_j)^{1-a_j}(h_j)^{a_j} w_{ij}$$
$$\ell = \sum_{j=1}^{n}(1-a_j)\ln(g_j)w_{ij} + \sum_{j=1}^{n}(a_j)\ln(h_j)w_{ij} \tag{8}$$

Where

$\mu_{1j} = e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}$ and $\mu_{2j} = e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}$

$\pi_j = \dfrac{e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}}{1+e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}}$ and $(1-\pi_j) = \dfrac{1}{1+e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}}$

$a_j = 1$ if $(y_{1j}, y_{2j}) \neq (0,0)$ and $a_j = 0$ otherwise. With w_{ij} is the geographical weighting. Ln likelihood of existing functions in equation (8) downgraded to each parameter $\boldsymbol{\beta}_1{}^{\mathbf{T}}(u_i,v_i), \boldsymbol{\beta}_2{}^{\mathbf{T}}(u_i,v_i), \boldsymbol{\gamma}^{\mathbf{T}}(u_i,v_i), \alpha$

$$\frac{\partial\ell}{\partial\boldsymbol{\beta}_1{}^{\mathbf{T}}(u_i,v_i)} = \sum_{j=1}^{n}(1-a_j)(P)(S)(w_{ij}) + \sum_{j=1}^{n}(a_j)Rw_{ij} \tag{9}$$

With

$$P = \left(\frac{e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}(\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)} - e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}))(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)})\mathbf{x_j}^{\mathbf{T}}}{1+e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}(\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)} - e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}))\left(1+\alpha(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}c))(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}c))\right)}\right)$$

$$S = \left(1+\alpha(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}c))(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}c)) + \alpha c(-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}c))(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}c))\right)$$

$$R = \left(\sum_{j=1}^{n} a_j(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}\mathbf{x_j}^{\mathbf{T}} + y_{1j}\mathbf{x_j}^{\mathbf{T}}) + \sum_{j=1}^{n} a_j \frac{\alpha c\mathbf{x_j}^{\mathbf{T}}(e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)})(-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}c))(e^{-y_{2j}} - \exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}c))}{1+\alpha(e^{-y_{1j}} - \exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}c))(e^{-y_{2j}} - \exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}c))}\right)$$

$$\frac{\partial\ell}{\partial\boldsymbol{\beta_2}^{\mathbf{T}}(u_i,v_i)} = \sum_{j=1}^{n}(1-a_j)(\frac{P}{S})w_{ij} + \sum_{j=1}^{n}(a_j)(R)w_{ij} \tag{10}$$

Where

$$P=\left(\begin{array}{l}\left[e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}\left(\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)})\right)(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)})\mathbf{x_j}^{\mathbf{T}}\right]*\\ \left[\begin{array}{l}1+\alpha(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}c))(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}c))+\\ \alpha c(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}c))(-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}c))\end{array}\right]\end{array}\right)$$

$$S=1+e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}\left(\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)})\right)\left(1+\alpha(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}c))(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}c))\right)$$

$$R=\sum_{j=1}^{n}a_j(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}\mathbf{x_j}^{\mathbf{T}}+y_{1j}\mathbf{x_j}^{\mathbf{T}})+\sum_{j=1}^{n}a_j\frac{\alpha c\mathbf{x_j}^{\mathbf{T}}(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)})(e^{-y_{1j}}-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}c))(-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}c))}{1+\alpha(e^{-y_{1j}}-\exp(-e^{\mathbf{x_{ji}}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}c))(-\exp(e^{-y_{2j}}-e^{\mathbf{x_{ji}}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}c))}$$

$$\frac{\partial\ell}{\partial\boldsymbol{\gamma}^{\mathbf{T}}(u_i,v_i)}=\sum_{j=1}^{n}(1-a_j)\left(-\frac{e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}}{1+e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}}\mathbf{x_j}^{\mathbf{T}}\right)w_{ij}+\sum_{j=1}^{n}(a_j)\mathbf{x_j}^{\mathbf{T}}\left(1-\frac{e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}}{1+e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}}\mathbf{x_j}^{\mathbf{T}}\right)w_{ij}+$$
$$\sum_{j=1}^{n}(1-a_j)\frac{e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}\left(\exp(-e^{\mathbf{x_{ji}}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)})\right)*\left(\begin{array}{l}1+\alpha(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}c))*\\(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}c))\end{array}\right)}{1+e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}\left(\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)})\right)*\left(\begin{array}{l}1+\alpha(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}c))*\\(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}c))\end{array}\right)}w_{ij} \quad (11)$$

$$\frac{\partial\ell}{\partial\alpha}=\sum_{j=1}^{n}(1-a_j)\frac{e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}(\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}))(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}c))(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}c))}{1+e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\gamma}(u_i,v_i)}\left(1+\alpha(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}c))(1-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}c))\right)}w_{ij}+$$
$$\sum_{j=1}^{n}a_j\frac{(e^{-y_{1j}}-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}c))(e^{-y_{2j}}-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}c))}{1+\alpha(e^{-y_{1j}}-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_1}(u_i,v_i)}c))(e^{-y_{2j}}-\exp(-e^{\mathbf{x_j}^{\mathbf{T}}\boldsymbol{\beta_2}(u_i,v_i)}c))}w_{ij} \quad (12)$$

The results of the first derivative of each parameter is explicit or not close the form that will be solved by Newton-Raphson iteration method as follows:

$$\boldsymbol{\theta}_{(m+1)}=\boldsymbol{\theta}_{(m)}-H^{-1}(\boldsymbol{\theta}_{(m)})g(\boldsymbol{\theta}_{(m)}) \quad (13)$$

Where

$$\boldsymbol{\theta}=(\alpha,\boldsymbol{\gamma}(u_i,v_i),\boldsymbol{\beta}_1^{\mathbf{T}}(u_i,v_i),\boldsymbol{\beta}_2^{\mathbf{T}}(u_i,v_i))^{\mathbf{T}} \quad (14)$$

$$g(\boldsymbol{\theta})=\left(\frac{\partial\ell}{\partial\alpha},\frac{\partial\ell}{\partial\boldsymbol{\gamma}(u_i,v_i)},\frac{\partial\ell}{\partial\boldsymbol{\beta}_1^{T}(u_i,v_i)},\frac{\partial\ell}{\partial\boldsymbol{\beta}_2^{T}(u_i,v_i)}\right)^{T} \quad (15)$$

$$\underset{(k+1)(k+1)}{\mathbf{H}(\boldsymbol{\theta}_{(m)})}=\begin{bmatrix}\frac{\partial^2\ell}{\partial\alpha^2} & \frac{\partial^2\ell}{\partial\alpha\partial\boldsymbol{\gamma}^{\mathbf{T}}(u_i,v_i)} & \frac{\partial^2\ell}{\partial\alpha\partial\boldsymbol{\beta_1}^{\mathbf{T}}(u_i,v_i)} & \frac{\partial^2\ell}{\partial\alpha\partial\boldsymbol{\beta_2}^{\mathbf{T}}(u_i,v_i)}\\ & \frac{\partial^2\ell}{\partial\boldsymbol{\gamma}(u_i,v_i)\partial\boldsymbol{\gamma}^{\mathbf{T}}(u_i,v_i)} & \frac{\partial^2\ell}{\partial\boldsymbol{\gamma}(u_i,v_i)\partial\boldsymbol{\beta_1}^{\mathbf{T}}(u_i,v_i)} & \frac{\partial^2\ell}{\partial\boldsymbol{\gamma}(u_i,v_i)\partial\boldsymbol{\beta_2}^{\mathbf{T}}(u_i,v_i)}\\ & & \frac{\partial^2\ell}{\partial\boldsymbol{\beta_1}(u_i,v_i)\partial\boldsymbol{\beta_1}^{\mathbf{T}}(u_i,v_i)} & \frac{\partial^2\ell}{\partial\boldsymbol{\beta_1}(u_i,v_i)\partial\boldsymbol{\beta_2}^{\mathbf{T}}(u_i,v_i)}\\ simetris & & & \frac{\partial^2\ell}{\partial\boldsymbol{\beta_2}(u_i,v_i)\partial\boldsymbol{\beta_2}^{\mathbf{T}}(u_i,v_i)}\end{bmatrix} \quad (16)$$

Hessian matrix is a matrix containing the second derivative of each parameter $\boldsymbol{\beta}_1(u_i,v_i),\boldsymbol{\beta}_2(u_i,v_i),\boldsymbol{\gamma}(u_i,v_i),\alpha$. Steps in parameter estimation using Newton Raphson iteration is as follows:

1. Determining the initial value of parameter.
2. Forming vector $g(\boldsymbol{\theta})(u_i,v_i)$ by substituting equation (9), (10), (11),and (12) into the equation(15)
3. Form the Hessian matrix $\mathbf{H}(\boldsymbol{\theta}_{(m)}(u_i,v_i))$ by substituting the second derivative of equation (9), (10), (11) and (12) to the equation (16).

4. Including the value of $\boldsymbol{\theta}_{(m)}(u_i, v_i)$ into vector elements $g(\boldsymbol{\theta}(u_i, v_i))$ and matrix $\mathbf{H}(\boldsymbol{\theta}_{(m)}(u_i, v_i))$ thus obtained gradient vector $g(\boldsymbol{\theta}_{(m)}(u_i, v_i))$ and Hessian matrix $\mathbf{H}(\boldsymbol{\theta}_{(m)}(u_i, v_i))$.
5. Starting from $m = 0$ to iterate the equation (13). $\boldsymbol{\theta}_{(m)}(u_i, v_i)$ is a set of parameter estimator which converges when iteration to m.
6. If you have not obtained when the parameter estimation convergent iteration to m, then proceed back to step 5 to $m+1$ iteration. Iteration will stop when the value of $\left\|\boldsymbol{\theta}_{(m+1)}(u_i, v_i) - \boldsymbol{\theta}_{(m)}(u_i, v_i)\right\| \le \varepsilon$, ε is number that is very small.

The test statistic in testing parameters for the GWR ZIP model determined by the likelihood function of the model is $L(\Omega)$ which is a maximum likelihood of complete models involving the predictor variables and $L(\omega)$ value is the maximum likelihood for a simple model without involving predictors. To determine the test statistic in testing parameters in this study, Maximum Likelihood Ratio Test (MLRT) is used.

$$\begin{aligned} G &= -2\ln\left(\frac{L(\omega)}{L(\Omega)}\right) \\ &= 2\ln\Big(L(\Omega) - L(\omega)\Big) \end{aligned}$$

RESULT

Estimation of model parameters of Geographically Weighted Bivariate Zero-inflated Poisson Regression using Maximum Likelihood Estimation by Newton-Raphson iteration, produces parameter estimates which do not close the form. The hypothesis is tested using Maximum Likelihood Ratio Test conducted simultaneously and partially by comparing H_0 and the following possibilities population.

***Abstract*—** Time series model is one of quantitative methods that frequently used for forecasting a number of train passengers in certain route. In general, there are two types of time series models, i.e. univariate and multivariate time series. The objective of this paper is to apply ARIMA model as a univariate method and VARIMA as a multivariate method for forecasting a number of executive train passengers in Indonesia, particularly Surabaya-Jakarta route. The number of daily train passengers in three types of executive classes that departure from Surabaya Pasar Turi station, i.e. Argo Bromo Anggrek Pagi, Argo Bromo Anggrek Malam, and Sembrani, are used as case study. The data are consisted 761 observations and recorded from January 1st, 2014 till February 27th, 2016 and divided into two parts, i.e. January 1st, 2014 to January 30th, 2016 and 1-27 February 2016 as training and testing data, respectively. Root mean of squares error (RMSE) in testing data is used as criteria to select the best forecasting model. The results show that ARIMA yields more accurate forecast at two data, i.e. number of passengers at Argo Bromo Anggrek Pagi and Sembrani, whereas VARIMA gives better forecast at Argo Bromo Anggrek Malam. Hence, this result inlines with the first conclusion of M3 competition, i.e. statistically sophisticated or complex methods do not necessarily provide more accurate forecasts than simpler ones.

Keywords: *forecasting, train passengers, ARIMA, VAR, RMSE.*

I. INTRODUCTION

The train is known as the mode of transport that has multiple advantages, such as energy saving, land-saving, environmentally friendly, high safety levels, able to transport large amounts, as well as adaptive to technological development [1]. The number of train tickets is sold uncertainty (fluctuatively) everyday. In general, the demand of train tickets at the weekend usually increase compared to normal days. Moreover, the peak of train tickets demand usually occurs one to five days ahead of Idul Fitri due to an annual *mudik* tradition in Indonesia. The term *mudik* refers to the exodus of Indonesian workers from the cities back to their hometowns ahead of Idul Fitri. Not only the Muslim community of Indonesia will return to their places of origin, but also people adhering to other religions traditionally use this public holiday to visit their parents or make a short holiday. This demand peak usually continues after Idul Fitri due to they must going back after this holiday.

A problem often faced by the railway operator is the large supply train ticket quotas are not appropriate to the number of train passengers. The number of train passengers usually increase in the days ahead of the national holidays or certain religious holidays. Due to the railway operator usually only provides the number of tickets as a normal day, this can lead to frustration of the passengers train because many passengers did not get a ticket. Hence, an accurate prediction of the number of rail passengers in the future is important to minimize the number of train passengers who did not get a ticket.

There are some researches on forecasting the train passengers have been conducted such as Andalita [2] who studied about forecasting the number of train passengers in economy class using ARIMA (Autoregressive Integrated Moving Average) and ANFIS (Adaptive Neuro Fuzzy Inference System) methods. Furthermore, Hermawan [3] applied the model NN (Neural Network) for forecasting the number of railway passengers in Jabodetabek. Additionally, Rosyidah [4] employed ARIMA modeling for forecasting of passenger trains on DAOP IX Jember.

In this research, forecasting the number of train passengers in executive class with univariate and multivariate time series. The data will be used is the number of train passengers in three executive trains, i.e. Argo Bromo Anggrek Pagi, Argo Bromo Anggrek Malam and Sembrani. The univariate time series modeling used ARIMA while the multivariate time series modeling employed Vector Autoregressive Integrated Moving Average (VARIMA). Modeling of multivariate time series are not only able to predict the number of passengers in the future, but also could explain the relevance of other types of executives trains. Once the best model of univariate and multivariate time series was obtained, the models were compared based on the accuracy to predict the number of train passengers. In forecasting, multivariate methods are usually more complicated than the univariate method. However as said by Makridakis and Hibon [5] that statistical methods are more sophisticated or more complicated does not always provide more accurate estimates than a simple method. Through the comparison of the two models time series derived from both methods will be obtained the best model to predict the number of rail passengers in the executive class Pasar Turi station.

II. Literature Review

A. Autoregressive Integrated Moving Average (ARIMA)

ARIMA(*p, d, q*) model is a combination of the AR (Autoregressive) order *p* model and MA (Moving Average) order *q* model with differencing order *d*. ARIMA model can be used in the seasonal and non-seasonal data. The ARIMA (*p, d, q*) can be written as follows [6]:

$$\phi_p(B)(1-B)^d Y_t = \mu + \theta_q(B)a_t,$$

Where μ is a constant, $\phi_p(B) = (1-\phi_1 B - \cdots - \phi_p B^p)$ is polynomial backshift operator for AR and $\theta_p(B) = (1-\theta_1 B - \cdots - \theta_q B^q)$ polynomial backshift operator for MA. The procedures used to obtain the forecasting value of using ARIMA consists of four steps starting from the model identification, parameter estimation, diagnostic testing and selection of the best models, forecasting. The identification can be done using ACF (Autocorrelation Function) and PACF (Partial Autocorrelation Function) plots. This step is valid if the time series is stationary that can be visually checked through time series plot. If the data is not stationary in mean, then do differencing whereas if the data is not stationary in variance, then the Box-Cox transformation can be used. The complete steps to do ARIMA modeling can be seen in [4].

B. Vector Autoregressive (VAR)

The VAR model with order one denoted as VAR(1) follows this equation [6]:

$$\boldsymbol{Y_t} = \phi_o + \boldsymbol{\Phi} Y_{t-1} + \boldsymbol{a}_t, \tag{2}$$

The model in (2) that consists of two series can be written in matrix form as follows:

$$\begin{bmatrix} Y_{1,t} \\ Y_{2,t} \end{bmatrix} = \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} + \begin{bmatrix} \phi_{11} & \phi_{12} \\ \phi_{21} & \phi_{22} \end{bmatrix} \begin{bmatrix} Y_{1,t-1} \\ Y_{2,t-1} \end{bmatrix} + \begin{bmatrix} a_{1,t} \\ a_{2,t} \end{bmatrix}, \tag{3}$$

In general, the VAR model of order p denotes as VAR (*p*) is formulates as [4]:

$$\boldsymbol{Y_t} = \phi_o + \boldsymbol{\Phi} Y_{t-1} + \cdots + \boldsymbol{\Phi}_p Y_{t-p} + \boldsymbol{a}_t. \tag{4}$$

The complete description of VAR model can be seen in [6].

C. Model Identification, Diagnostic Checking, and Model Selection

Identification of time series model can be done by creating ACF and PACF plots for the univariate models. The identification step for the multivariate models can be done by employing MPACF (Matrix of Partial Autoregression Function) and the AIC (Akaike Information Criterion) [6].

Checking the assumptions of model is conducted after the identification and parameter estimation steps. The purpose of this step is to determine whether the model fulfills the assumptions. The ARIMA model assumes that the residual is white noise and normally distributed whereas the VARIMA model assumes that the vector of residual is white noise and follows multivariate normal distribution [6].

Selection of the appropriate model was done based on smallest RMSE (Root Mean Squared Error) of out of sample data. The RMSE is calculated as follows [6].

$$\text{RMSE}_{out\ of\ sample} = \sqrt{\frac{1}{L}\sum_{l=1}^{L}\left(Y_{n+l} - \hat{Y}_n(l)\right)^2}.$$

with L is number of observation in out of sample data, Y_{n+l} is observation l in out sample, and $Y_n(l)$ is the value of l-step forecasting.

III. RESEARCH METHODOLOGY

A. Data and Variables

The data used in the study were the data of the number passengers in daily train executive class with Surabaya-Jakarta route in the period from January 1, 2014, until February 29, 2016. These data are secondary data which obtained from Pasar Turi Train Station. There are three types of train executive class data, i.e. the number of passengers in the train Argo Bromo Anggrek Pagi, the number of Sembrani train's passengers, and the number of Argo Bromo Anggrek Malam passengers.

The variables in this study are denoted by $Y_{m,t}$ with m is stating the type of trains and t is stating the time (days). Following is the details of the variables in the study:

$Y_{1,t}$: The daily number of Argo Bromo Anggrek Pagi train passengers

$Y_{2,t}$: The daily number of Argo Bromo Anggrek Malam train passengers

$Y_{3,t}$: The daily number of Sembrani train passengers.

B. Steps of Analysis

1. ARIMA modeling with the following steps:
   a) Stationary inspection of data by looking at the data, ACF and PACF plots. If the data is not stationary variance, we can transform this data. If the data is not stationary in mean, we can difference this data. Formally, Augmented Dickey-Fuller test is used to check the data in the stationary mean.
   b) Identification of the model by ACF and PACF plots to determine the order of AR and MA
   c) Parameter estimation using OLS method.
   d) Selection of the best model by AIC criterion.
   e) Diagnosis check.
   f) Forecasting for data out samples with the selected order.
2. VAR modeling with the following steps:
   a) Inspection stationary of data such as the ARIMA model.
   b) To identify the model by MPACF and minimum AIC value thus obtained VAR order.
   c) Diagnosis check.
   d) Forecasting for data out samples with the model selected.
3. Compare the best model between univariate and multivariate models that have been selected.

IV. ANALYSIS AND RESULTS

A. Descriptive Statistics

The first step in this study was dividing the data into in sample, i.e. January 1, 2014 until January 14, 2015, and out of sample data span from January 15 until February 29, 2016. The descriptive statistics of the data are presented in Table 1. The largest average of the number of train passengers is for train ABAP (Argo Bromo Anggrek Pagi), followed by train ABAM (Argo Bromo Anggrek Malam) and Sembrani. However, the variance for Sembrani is the largest. The correlation between number of train passengers across trains are shown in Table 2.

TABEL 1. DESCRIPTIVE STATISTICS FOR THE NUMBER OF TRAIN PASSENGERS

Train	Average	Variance	Minimum	Maximum
ABAP	350	6304	129	635
ABAM	338	5072	109	540
Sembrani	317	6307	98	544

TABEL 2. CORRELATION OF NUMBER OF PASSENGERS OF BETWEEN TRAINS

Train	ABAP	ABAM	Sembrani
ABAP	1	-	-
ABAM	0.677	1	-
Sembrani	0.666	0.761	1

Table 2 shows that number of passengers between trains are correlated. The strongest correlation is between ABAM and Sembrani. All the correlation are significant with *p*-values are less than 0.05. These facts motivated the use of multivariate time series to model the data.

B. ARIMA Model

ARIMA modeling begins with the identification step given the series stationary. Following is time series plot of the three train's passenger data: ABAP (left), ABAM (middle), and Sembrani (right). Based on time series plot in Figure 1, the data seems to be not stationary. They have high fluctuations. In order to know the stationary of these data, the Box-Cox transformation was used to check it where the results were reported in Table 3.

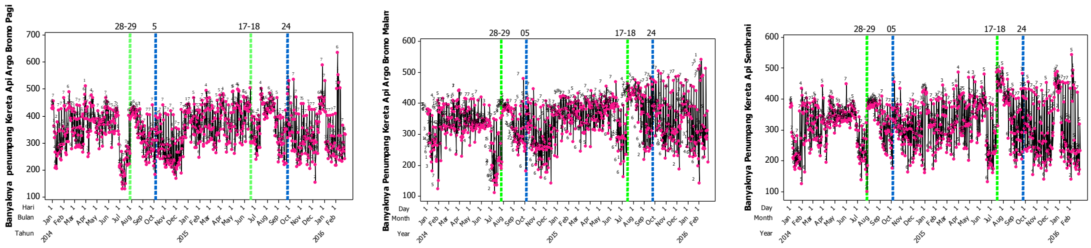

FIGURE 1. TIME SERIES PLOT OF NUMBER OF PASSENGERS TRAINS

TABEL 3. BOX-COX TRANSFORMATION

Variable	Rounded Value	Lower Limit	Upper Limit
ABAP	1	0.82	1.48
ABAM	1.36	1.06	1.71
Sembrani	1.33	1.06	1.65

In the ABAP, the rounded value for the parameter estimate in Box-Cox transformation is one. This indicates that only the ABAP variables are stationary in variance. The series for ABAM and Sembrani are required to be transformed. The next step is to check the stationary in the mean. The checking can be viewed via time series plot and ACF. ACF plot shows a form of a cut off pattern. This shows that the data has not been stationary in the mean. It is necessary to do differencing, i.e. differencing order one and seven. After differencing, the next step is to look at the ACF and PACF plot of the data that has been stationary. Through ACF and PACF plot can be determined the order of ARIMA models. The ACF and PACF plots had been stationary using differencing order one and seven.

The ARIMA models for the ABAP data is ARIMA (0, 1, 1) $(0, 1, 1)^7$ because the ACF plot occurs in the lag 1,6,7,8 are cut off. The modeling for ABAM and Sembrani series need an outlier detection approach because the normality assumption in ARIMA models was not fulfilled. The model for ABAM series is ARIMA ([6,7,8], 1,2)$(0,1,1)^7$ with few outliers whereas the model for Sembrani is ARIMA (7, 1, 1) $(0, 1, 1)^7$ with few outliers. All models have fulfilled the assumptions, i.e. white noise and normality distribution. Thus, the model for $Y_{1,t}$ is:

$$Y_{1,t} = Y_{t-1} + Y_{t-7} - 0.610a_{t-1} - 0.812a_{t-7} + a_{1,t}.$$

The model for $Y_{2,t}$ is:

$$Y_{2,t} = \frac{(1-0.29B-0.21B^2)(1-0.83B^7)}{(1+0.10B^6-0.3B^7+0.27B^8)} a_t + W_{AO} I_t^{(T)}$$

with $W_{AO} I_t^{(T)}$ is:

$$\begin{aligned}
&= -2554.1I_t^{(33)} - 2033.3I_t^{(458)} - 2144.5I_t^{(31)} + 2173.8I_t^{(634)} + 1350.5I_t^{(631)} - 950.3I_t^{(453)} - 1040.3I_t^{(365)} - 1438.7I_t^{(416)} + \\
&\quad - 1548.3I_t^{(39)} + 1116.1I_t^{(452)} - 1389.1I_t^{(486)} + 1084.6I_t^{(14)} + 1224.9I_t^{(107)} + 1103.6I_t^{(271)} + 1116.4I_t^{(361)} - 1031.4I_t^{(208)} + \\
&\quad - 943.9I_t^{(347)} + 741.7I_t^{(689)} - 1447.5I_t^{(609)} - 1319.0I_t^{(610)} + 1154.7I_t^{(358)} + 1046.4I_t^{(134)} - 687.0I_t^{(730)} + 1005.9I_t^{(291)} + \\
&\quad - 979.1I_t^{(121)} + 1025.2I_t^{(10)} + 1028.4I_t^{(705)} + 1016.3I_t^{(551)} + 1169.0I_t^{(206)} + 1006.7I_t^{(444)} + 1272.1I_t^{(187)} + 1168.1I_t^{(194)} + \\
&\quad 986.8I_t^{(190)} + 781.8I_t^{(176)} + 792.9I_t^{(594)} + 974.8I_t^{(718)} + 838.5I_t^{(161)} - 822.2I_t^{(632)} - 764.6I_t^{(707)} - 1029.9I_t^{(38)} + 881.5I_t^{(652)} + \\
&\quad 1234.4I_t^{(655)} + 1093.3I_t^{(648)} + 830.7I_t^{(280)} - 735.4I_t^{(431)} + 492.5I_t^{(725)} + 1006.2I_t^{(326)} + 634.1I_t^{(269)} - 707.4I_t^{(337)} + 612.4I_t^{(297)} + \\
&\quad 961.5I_t^{(199)} - 824.9I_t^{(471)} + 904.5I_t^{(681)} + 717.4I_t^{(16)} + 1384.1I_t^{(30)} - 595.1I_t^{(92)} + 696.7I_t^{(152)} + 724.2I_t^{(211)} - 842.2I_t^{(311)} + \\
&\quad 522.7I_t^{(455)} - 502.7I_t^{(533)} - 662.8I_t^{(483)} - 699.6I_t^{(378)} + 649.4I_t^{(185)} + 659.9I_t^{(414)}.
\end{aligned}$$

The model for $Y_{3,t}$ is :

$$Y_{3,t} = \frac{(1-0.44B)(1-0.88B)^7}{(1+0.09B^2-0.28B^7+0.12B^8)} a_t + W_{AO} I_t^{(T)} + W_{ls} I_t^{(T)},$$

with $W_{AO} I_t^{(T)}$ and $W_{ls} I_t^{(T)}$ is:

$$\begin{aligned}
&= 2334.9I_t^{(631)} - 1249.5I_t^{(31)} + 1786.0I_t^{(452)} - 1467.7I_t^{(486)} + 1243.9I_t^{(457)} + 1299.5I_t^{(358)} + 1441.3I_t^{(414)} - 1538.4I_t^{(39)} + \\
&\quad - 1131.3I_t^{(530)} + 1268.8I_t^{(485)} + 1296.6I_t^{(444)} - 1689.9I_t^{(366)} - 1392.7I_t^{(208)} + 1211.1I_t^{(306)} + 1396.1I_t^{(636)} + -1237.3I_t^{(458)} \\
&\quad + 1123I_t^{(498)} + 1073.9I_t^{(696)} + 1098.0I_t^{(87)} - 1075.6I_t^{(283)} + 1003.5I_t^{(368)} + 1024I_t^{(623)} - 1000.2I_t^{(416)} - 888.9I_t^{(564)} - 973.2I_t^{(53)} + \\
&\quad 981.5I_t^{(735)} + 896.8I_t^{(402)} - 1122.5I_t^{(736)} - 1630.6I_t^{(365)} + 1523.4I_t^{(30)} + 1372.3I_t^{(634)} - 1060.0I_t^{(737)} + 1559.4I_t^{(361)} + \\
&-654.8I_t^{(5)}.
\end{aligned}$$

C. VARIMA Model

VARIMA modeling begins with the identification step based on MACF and MPACF plots and AIC. The series for three train passenger were differenced order one and seven because the data are not stationary in the mean. These series were transformed using Box-Cox transformation because they are not stationary in variance. The minimum value of the AIC indicated that the proper model is VARIMA $(30,1,0)(0,1,0)^7$.

The results of parameter estimation of VARIMA $(30,1,0)(0,1,0)^7$ indicates that the model has 270 parameters. However, the *p*-value of each parameter some parameters were not significant. So, the model need restrict some parameters. This restriction process start from the parameter estimate with the highest *p*-value until all parameter estimates had *p*-value less than Type-I error (α = 0.05). The results of parameter estimation VARIMA $(30,1,0)(0,1,0)^7$ with restriction showed that there are 78 parameters that were significant in the model. The VARIMA $(30,1,0)(0,1,0)^7$ model for the series of the number of train passengers is:

$$

Based on the model that had been established, the next step is testing the assumptions on residual. In multivariate time series modeling, to testing the assumption of white noise on the residual can be done by looking at the results of the portmanteau test. In this study, testing the white noise used AIC criterion calculated from the residual of VARIMA $(30,1,0)(0,1,0)^7$ model. Based on Table 4, the smallest AIC value is in AR (0) and MA (0). This suggests that the residuals of the model have fulfilled the white noise assumption.

AR(0)	27.26852	27.32797	27.32771	27.32819	27.32541	27.3277
AR(1)	27.28481	27.31673	27.32693	27.3307	27.33645	27.34313
AR(2)	27.29714	27.32953	27.33551	27.33822	27.34943	27.35946
AR(3)	27.3034	27.3347	27.33804	27.34664	27.35837	27.37177
AR(4)	27.30585	27.3421	27.35016	27.35857	27.37946	27.39254
AR(5)	27.31611	27.35402	27.36436	27.37477	27.39558	27.4099

The next assumption that must be fulfilled is multivariate normal distribution for the vector of residual. The null hypothesis of the test is that the residuals follows have multivariate normal distribution. The null hypothesis will be fail to be rejected if the *p*-value of the statistic test exceed the value of Type-I error. The evaluation of the multivariate normal assumption test can also be done visually through QQ plot of the residual. The assumption is fulfilled when residual plot tends to form a straight diagonal line as displayed by Figure 2. Moreover, if the proportion of values which generated through calculation are at least 50% greater than the value of statistic test, in this study is about 83%, the null hypothesis is fail to be rejected. Therefore, residuals of the VARIMA $(30,1,0)(0,1,0)^7$ model have multivariate normal distribution.

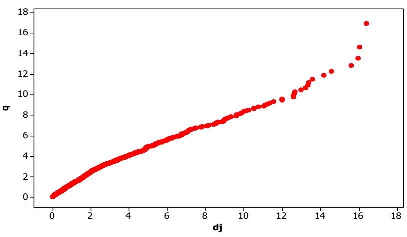

FIGURE 2. QQ PLOT FOR RESIDUALS

Once the best model for ARIMA and VARIMA were obtained, the out of sample forecast can be calculated for the series. The RMSE out of the samples were reported in Table 5. The models for ABAP and Sembrani have relatively large RMSE for both univariate and multivariate models. This indicates that the two models are less good than the model for ABAM. The comparison of RMSE out samples for univariate and multivariate models indicated that multivariate model, which is more complex, were not always resulted in better prediction than the simpler model. Often in some studies suggest that more complicated method will yield better accuracy but the reality is not always so. Table 6 reported the forecasting value obtained from ARIMA model for each train.

TABEL 5. THE COMPARISON RMSE OUT OF SAMPLE FOR UNIVARIATE AND MULTIVARIATE

Variable	RMSE Out of Sample for ARIMA	RMSE Out of Sample for VARIMA
ABAP	111.5	133.8
ABAM	91.2	77.5
Sembrani	102.1	120.0

V. CONCLUSIONS AND RECOMMENDATIONS

The empirical results found that the best model for univariate approach to model number of passenger train are ARIMA $(0,1,1)(0,1,1)^7$ for Argo Bromo Anggrek Pagi, ARIMA$([6,7,8],1,2)(0,1,1)^7$ with outliers detection for Argo Bromo Anggrek Malam, and ARIMA $(7,1,1)(0,1,1)^7$ with outliers detection for Sembrani. The multivariate models appropriate to model these three series is VARIMA $(30,1,0)$ $(0,1,0)^7$. Based on the RMSE value for out of sample data, it can be concluded that the ARIMA model had better prediction for two series whereas the VARIMA model outperformed in one series, i.e. series for Argo Bromo Anggrek Malam.

The empirical results also showed that many outliers were found in the data and influenced the forecast accuracy of both univariate and multivariate models. Hence, more detail about outlier detection can be done for further research. Moreover, non linear time series models such as ANN (Artificial Neural Network) which is flexible to overcome data with outliers also could be considered as a future research for forecasting train passengers in Indonesia.

Derivation of One Dimensional Continuity Equation for Fluid Flows in Deformable Pipelines

Nur Endah Ardiyanti[1], Nikenasih Binatari[2]
[1,2]Department of Mathematics, Yogyakarta State University, Indonesia
Nurendah1205@gmail.com

***Abstract*—**This paper discusses the derivation of one dimensional continuity equation for fluid flows in deformable pipelines. In this case, the meaning of deformable pipelines is the pipe cross-sectional area change due to fluid flow. In this paper, it is assumed homogeneous fluid, the flow is laminar, and always fill each section of pipelines. In the process of the derivation of continuity equation for fluid flows, we used the Mass Conservation Law. The mass change of fluid flow at each time equals to zero, or in other words, the incoming mass equals to the mass coming out. To find a mass of fluid flow, we used the concept of a fluid density and integral concept of Leibniz. Integral limit on the mass of fluid flow changes at any time and mass fluid flow will be differentiated with respect to time, so we need to use the integral concept of Leibniz. Based on the Mass Conservation Law, we concludeD that the fluid flow mass derivative with respect to time is equal to zero. Thus, we got the equation of mass fluid flow derivative with respect to time is equal to zero, which then called as continuous fluid flow equations.

Keywords:*fluid flows, continuity equation, deformable pipelines.*

I. INTRODUCTION

Many everyday events in our environment are examples of the flow of liquid or gas for example the flow of water from the faucet, water flowing from a hole bath, the flow of gas in the regulator, and others. The natural disasters that have occurred in Indonesia are also the examples of a flow such as, floods, tsunamis, volcanic eruptions due to the lava flow, and the spread of smoke from forest fires. That events and natural disasters have the same basic, the liquid or gas flow. In physics, the amount that can flow included liquids and gases is called the fluid. Therefore, the authors are interested in analyzing mathematical modeling of the fluid flow. Fluid flow basically have boundary. In this paper, the fluid is confined in a space which later we called is as a pipeline.

There are several researches about mathematical modeling of the fluid flow that have been done which one of them is by Zusnita Meyrawati. Zusnita have analyzed the mathematical modeling of gas in pipeline[1]. While, Dr. Ir. Ahmad Indra S, Ridwan ST.MT, and Irwan Setiawan have analyzed fluid flow in spiral pipe [2]. But, both of them analyzed fluid flow in the undeformable pipeline. In this paper, the mathematical modeling of the fluid flow will be analyzed in the deformable pipeline.

In our environment, fluid flows continuously. Moreover, mathematical model which is representing it is the fluid continuity equation. In the research before, the continuity equation of fluid in the pipe were analyzed with pipes that can not be deformed. Therefore, in this paper will be discussed about the derivation of one dimensional continuity equation for fluid flows in deformable pipelines and the fluid will be analyzed as the arrangement of the particles that establish the fluid. In this case, the deformable pipeline is the pipe cross-sectional area size changes.

II. METHODS

In the derivation of fluid continuity equation, we used the following steps to make it easier to get fluid continuity equation.

1. Study the literature of the fluid and the continuity equation.
   A literature study by studying some books, journals, and papers of fluid flow and continuity equation.

2. Analyze the fluid flow and fluid characteristics.
   After studying fluid flow, then we analyzed the fluid flow and the characteristics of the fluid flow. In this paper, to obtain a fluid continuity equation, we need to analyze the mass of fluid flow.
3. Assumptions to ease the derivation of fluid continuity equation.
   The assumption is required to ease the authors in the derivation of the fluid continuity equation.
4. Formulate the mass of fluid flow.
   Mass of fluid flow is analyzed by assuming the fluid flow is a composition of small particles. These particles are partitions of fluid flow in the pipe.
5. Formulate the fluid continuity equation.
   Fluid continuity equation obtained after we get the mass of fluid flow. This is because the fluid continuity equation is the development of mass conservation law. In addition, the derivation process of fluid continuity equations, used some of the rules of derivatives and integrals.

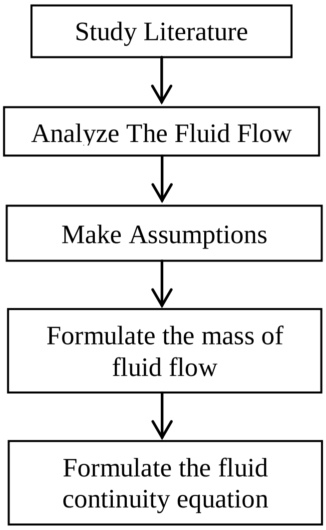

FIGURE 1. THE STEPS OF DERIVATION OF FLUID FLOW EQUATION

III. DERIVATION OF FLUID CONTINUITY EQUATION

Fluid is a substance that can deform continuously, when it was exposed by shear stress, however small it is [3]. Fluid is something that can flow, so it is often referred to as a flow agent, can be either a liquid or gas. Liquid and gas phases have the characters do not maintain a fixed shape, so that both have the ability to flow, thus both called fluids. Actually, fluid flow is not a simple phenomenon and it occurs in three dimensional and also dependent with time. However, in many situations, it can be assumed with the simplification of fluid flow to make much easier understanding on the issue of the flow without compromising the level of accuracy required. One of this simplification is the real flow approach (in fact) as a stream of simple one or two-dimensional [4].

In the derivation of the fluid continuity equation, we used the dynamic fluid as it moves continuously. The fluid is assumed that always fill all parts of the pipe continuously. The assumptions in the flow process using the conditions as below.

1. Real Fluid.
   The fluid is a real fluid (not the ideal fluid). Real fluid has a viscosity, while ideal fluid has no viscous or without friction.
2. The fluid is a homogeneous fluid.
   Homogeneous fluid is a fluid that is not derived from a mixture of several substances, so that the fluid does not have a concentration but has a density.
3. Fluid always filled the entire section of pipe continuously.
   The flow of fluid has never stopped.The fluid always flowing and filled the pipelines.
4. Fluid flow is laminar flow or straight flow.
   Laminar flow is the flow of entire fluid particles move along a straight line parallel and follow the flow direction (or parallel to the center line of the pipe, if the fluid flowing in the pipe).

5. The fluid flows only to the direction of positive abscissa.
   The fluid flows toward the positive abscissa and does not flow toward the negative abscissa and does not flow toward the ordinate.

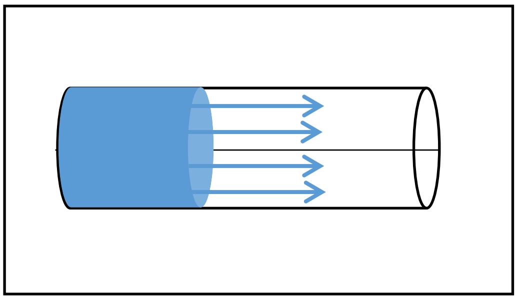

FIGURE 2. ILLUSTRATION OF LAMINAR FLOW AND POSITIVE ABSCISSA DIRECTION

6. The viscosity (thickness) of fluid is constant.
   Fluid viscosity is constant with respect to the fluid is a homogeneous fluid.
7. Friction which in line with ordinate is ignored.
   Fluid flows toward the positive abscissa, so that the frictional forces that considered only the frictional forces in the direction of the abscissa.

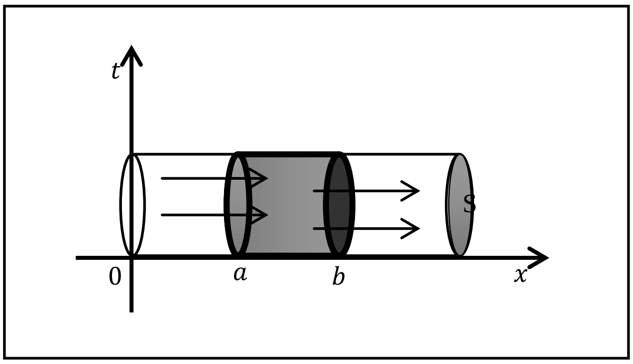

FIGURE 3. FLUID FLOW IN PIPELINE

The continuity equation is the development of Mass Conservation Law. The Mass Conservation Law is the mass of the incoming fluid flow is equal to the mass of fluid flow out [5]. Therefore, the mass of fluid flow in the pipe is required to obtain a fluid continuity equation. To analyze the mass of fluid flow mathematically, the fluid analyzed from tiny particles contained in the fluid. Mass of fluid flow is obtained by adding the masses every partition or small particles in the fluid. Figure 2.2 above is an illustration of the fluid flowing in the pipe. Interval [a, b] is selected to analyze the mass of fluid flow in the pipe. At the interval [a, b] is partitioned into n partitions, in order to obtain part of the partition that $[x_i, x_{i+1}]$ with $i = 1,2,3, \ldots, n$and $x_{i+1} - x_i = \Delta x$. For more details, can be seen in Figure 3 below.

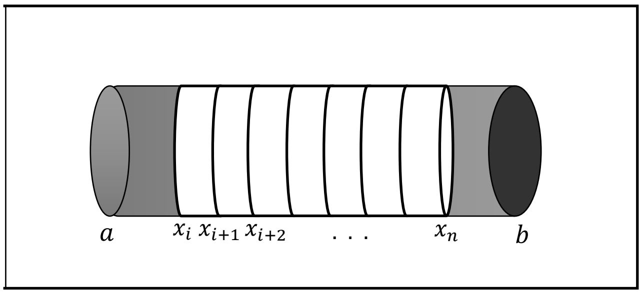

FIGURE 4. PARTITIONS OF FLUID FLOW IN INTERVAL [A,B]

Mass of fluid flow(M) is the sum of the mass (m) of region i to region $i+1$. A mass equal to the product of the fluid density (ρ) and volume (V) [6]. To analyze the volume of fluid partition, used the assumption that the volume of partition equals to the volume of the tube. Volume of tube is the multiplication between the base area andheightof the tube. In this case, the base area is equal to the pipe cross-sectional area (S) and a height equal to Δx. Fluid density (ρ), volume (V) and the pipe cross-sectional area (S) is not constant at any point within the fluid. Suppose that there are $x_i^* \in [x_i, x_{i+1}]$, the masses in the region $[x_i, x_{i+1}]$ can be written as follows.

$$m_i = \rho(x_i^*, t) \cdot S(x_i^*, t).\Delta x \tag{1}$$

Equation (1) is the mass of region i to region $i+1$. From (1) obtained the approach of a fluid flow mass value (M) as follows.

$$M \approx \sum_{i-1}^{n} m_i \tag{2}$$

Equation (1) substituted into (2), so that

$$M \approx \sum_{i=1}^{n} \rho(x_i^*, t) \cdot S(x_i^*, t).\Delta x \tag{3}$$

The value of M in (3) is an approximation of fluid flow mass value (M). To get the actual value of M, we used the limit value with n is infinity (given the presence of n infinity partitions on the interval [a,b]). Therefore, we got the value of M as follows.

$$M = \lim_{n\to\infty} \sum_{i-1}^{n} \rho(x_i^*, t) \cdot S(x_i^*, t) \cdot \Delta x \tag{4}$$

According to the definition of the Riemann Integral [7] which states that let M is a function defined on a closed interval [a,b], such that the value of M there, and M integral on the interval [a,b], so that (4) into

$$M = \int_a^b \rho(x,t) \cdot S(x,t) dx \tag{5}$$

with a and b is a function on t.

The continuity equation is the development of Mass Conservation Law which is the mass of the incoming fluid flow is equal to the mass of fluid flow out, so the changes of mass of the fluid flow at each time is equal to zero.

$$\frac{dM}{dt} = 0 \tag{6}$$

Equation (5) substituted into (6), so we obtain

$$\frac{d}{dt} \int_a^b \rho(x,t) \cdot S(x,t) dx = 0 \tag{7}$$

Boundary integral a and b is a function on t, based on Leibniz integral rule, so (7) can be writen into the following

$$\frac{d}{dt} \int_a^b \rho(x,t) \cdot S(x,t) dx = \int_a^b \frac{\partial}{\partial t} [\rho(x,t) \cdot S(x,t)] dx + \rho(x,t) \cdot S(x,t)\Big|_b \frac{db}{dt} - \rho(x,t) \cdot S(x,t)\Big|_a \frac{da}{dt}$$

For the case of liquid media volume, the value of db/dt and da/dt is equal to the speed at the time of b and a. Therefore,

$$\frac{d}{dt}\int_a^b \rho(x,t)\cdot S(x,t)dx = \int_a^b \frac{\partial}{\partial t}[\rho(x,t)\cdot S(x,t)]dx + \rho(x,t)\cdot v(x,t)\cdot S(x,t)\Big|_b - \rho(x,t)\cdot v(x,t)\cdot S(x,t)\Big|_a \quad (8)$$

Based on the Calculus Base Theorem I [7],

$$\rho(x,t)\cdot v(x,t)\cdot S(x,t)\Big|_b - \rho(x,t)\cdot v(x,t)\cdot S(x,t)\Big|_a = \int_a^b \frac{\partial}{\partial x}[\rho(x,t)\cdot v(x,t)\cdot S(x,t)]dx$$

Equation (8) becomes

$$\frac{d}{dt}\int_a^b \rho(x,t)\cdot S(x,t)dx = \int_a^b \frac{\partial}{\partial t}[\rho(x,t)\cdot S(x,t)]dx + \int_a^b \frac{\partial}{\partial x}[\rho(x,t)\cdot v(x,t)\cdot S(x,t)]dx \quad (9)$$

Equation (9) is simplified by using the definition of the total derivative, so we obtain

$$\frac{d}{dt}\int_a^b \rho(x,t)\cdot S(x,t)dx = \int_a^b \left(\frac{\partial \rho S}{\partial t} + \frac{\partial \rho v S}{\partial x}\right)dx \quad (10)$$

Based on the equation (7) and (10) can be obtained that

$$\int_a^b \left(\frac{\partial \rho S}{\partial t} + \frac{\partial \rho v S}{\partial x}\right)dx = 0 \quad (11)$$

According to Integral Theorem, if the integral of a function is equal to zero, the function is a function to zero, so that (11) becomes

$$\frac{\partial \rho S}{\partial t} + \frac{\partial \rho v S}{\partial x} = 0 \quad (12)$$

Equation (12) is called the Continuity Equation of Fluid in Pipe.

III.CONCLUSION

This paper was created to analyze to derivatethe one dimensional continuity equation for fluid flows in deformable pipelines.. In this case, deformable pipelines is the pipe cross-sectional area size changes. The fluid is a real fluid and homogeneous fluid. We used laminar flow or straight flow. The fluid flows only to the direction of positive abscissa. Fluid flows continuously in the pipeline, and the fluid is always filled each part of the pipeline.

Fluid continuity equation is the development of the Mass Conservation Law. Therefore, it is necessary to analyze the mass of fluid flow in the pipelines. To analyze the mass of fluid flow mathematically, the fluid analyzed from small particles in the fluid, so that the fluid in the pipe is partitioned into infinite parts. Approach mass fluid flow is obtained by totaling the masses every partition or small particles in the fluid. To obtain a mass of fluid flow, usable limit of the sum of masses each partition.

In the process of the derivative of fluid continuity equation, integral limit on the mass of fluid flow changes at any time and mass fluid flow will be differentiated with respect to time, so we need to use the integral concept of Leibniz. Based on the Mass Conservation Law, we concluded that the fluid flow mass derivative with respect to time is equal to zero. Thus, we got the equation of fluid flow mass derivative with respect to time is equal to zero, which is called the continuity equation of fluid flow.

Abstract— *Time series data analysis is a method for modeling a data pattern. Forecasting is one of the main points in a time series analysis. difficult to choose the method of parametric models that are not linear. Before forecasting time series data nonlinearity testing should be done in order to explain the nonlinear relationships in the variable and testing procedures to detect the presence of nonlinear relationships. Some alternative methods that can be used to test the nonlinearity is Ramsey's RESET test, White test and Terasvirta test. Ramsey's RESET test is a test used to detect nonlinearity using general tests for specification error (Gujarati, 1996). White Test is a test developed to detect nonlinearity of neural network models were invented by White (1989). Terasvirta test is a test used to detect nonlinearity were also developed from neural network models and are included in the test group developed type of Lagrange Multiplier with Taylor expansion (Terasvirta, 1993). The purpose of this study was to demonstrate that the data on the number of foreign tourists is the data nonlinear with nonlinearity is tested using three methods: Ramsey's RESET test, White test and Terasvirta test. In this study will use data on the number of foreign tourists at Juanda airport in 2000 until 2015.*

Keywords: *nonlinearity test, time series data, number of foreign tourists*

I. INTRODUCTION

Time series data is a series of observations on a value taken at different times. Time series data is data in chronological order. Time Series is a series of variables that form the observation values observed from time to time and recorded in accordance with the sequence of events and the data is assumed to be interdependent with one another (dependent). Such data can be collected periodically at certain time intervals, such as daily, weekly, monthly, or yearly. Autoregressive which is one of the Time Series models, first introduced by [8] and later developed by [5]. Autoregressive models of order p or AR (p) states that the value of observation all t depend on the values of p observations throughout the previous period.

But in some cases, the relationship between the data have shaped nonlinear tendencies. Based on these cases, necessary to test to show time series data used in the model included linear or nonlinear models. The test can be used to indicate that data be linear or nonlinear. There are some test that can be used to show the nonlinearity. Non linearity test used in this study were White test, Ramsey's RESET test and Terasvirta test. Ramsey's RESET test is a test used to detect nonlinearity using general tests for specification error [1]. White Test is a test developed to detect nonlinearity of neural network models were invented by [7]. Terasvirta test is a test used to detect nonlinearity were also developed from neural network models and are included in the test group developed type of Lagrange Multiplier with Taylor expansion [3].

several studies using non-linear models such, testing for nonlinearity in time series: the method of surrogate data [4] indicating that correctly identifies nonlinearity in several well-known examples of low-dimensional chaotic time series, event when contaminated with dynamical and observational noise.

linearity test data time series with reset test [6] showed the results of the data generated from nonlinear models produce nonlinearitas significant at 5%.

based on previous studies, the test nonlinearitas actually quite important in identifying the time series data that is used for helping to sort the data in the model is a linear or nonlinear models. if included in the linear model can be regressed using a parametric regression otherwise if included in the nonlinear model can be regressed using nonparametric regression or semiparametric regression. Therefore in this study, the test will be conducted non-linearity in the time series data. time series data used is data on the number of foreign tourists at the airport juanda in 2000 to 2015.

II. AUTOREGRESSIVE MODEL

Autoregressive model is a model that describes the dependent variable influenced by the dependent variable itself in periods previously, or autocorrelation can be interpreted also as a linear correlation sequence periodically with time series itself with a time difference (lag) 0, 1, 2 or more periods. The general form autoregressive model with order p or written with AR (p) has the following equation:

$$Y_t = \phi_1 Y_{t-1} + \phi_2 Y_{t-2} + \ldots + \phi_p Y_{t-p} + e_t \quad (1)$$

Where:
Y_t = the value of a variable at t
ϕ_i = autocorrelation parameter i-th with i= 1,2,...,p
e_t = error value in t

A. *Autoregressive 1*

AR order are often used in time series analysis is p = 1 is a model AR (1). AR (1) stated that the observed values to t depends on the values of the observations throughout the previous period. The general form autoregressive model with order 1 or written with AR (1) has the following equation:

$$Y_t = \phi_1 Y_{t-1} + e_t \quad (2)$$

Where:
Y_t = the value of a variable at t
ϕ_1 = autocorrelation parameter
e_t = error value in t

III. NONLINEARITY TEST

According to [2] some tests to detect non-linear relationships between variables in time series analysis. in this section the discussion focused on the detection nonlinearitas on a time series model, particularly Ramsey's RESET test, test and test Terasvirta White. The following is an explanation for each of the nonlinearitas test.

A. *Ramsey's RESET test*

Ramsey has proposed a general test of specification error called RESET (regression specification error test). The general shape models describing the relationship among the independent variables (predictors) and the dependent variable (response) can be written:

$$Y = f\left(X\right) + \varepsilon \quad (3)$$

Hypothesis testing used in the test are the nonlinearitas:
$H_0 : f\left(X\right)$ is a linear function of the X or the linear model
$H_1 : f\left(X\right)$ is a nonlinear function of the X or the nonlinear model

H_0 is rejected, which means non-linear model is appropriate, if the value of the F test meets namely the rejection region

$$F > F_{\alpha;(df_1,df_2)} \text{ atau } p\text{-}value < \alpha \quad (4)$$

The following steps in the RESET test by [1]:

1. Regression of Y_t on $1, x_1, x_2, ..., x_p$ and calculate the estimated values of the response variable $\hat{Y}_t$, so:
$$\hat{Y}_t = \beta_0 + \beta_1 x_1 + \ldots + \beta_p x_p \tag{5}$$
Calculate the coefficient of determination of the regression, the R^2 and further denote the R_{old}^2.
2. Regression of Y_t on $1, x_1, x_2, ..., x_p$ and 2 additional predictors that $\hat{Y}_t^2$ and $\hat{Y}_t^3$ calculate the estimated values of the response variable $\hat{Y}_t$, so:
$$\hat{Y}_t = \beta_0 + \beta_1 x_1 + \ldots + \beta_p x_p \tag{6}$$
Calculate the coefficient of determination of the regression, the R^2 and further denote the R_{old}^2.
3. Calculate F test score
$$F = \frac{\left(R_{new}^2 - R_{old}^2\right)/m}{\left(1 - R_{new}^2\right)/\left(n - p - 1 - m\right)} \tag{7}$$
Where:

   m: additional predictors

   p: early predictors

   n: number of data in used
4. Based on the hypothesis of linearity, shows F test values approaching F distribution with degrees of freedom of m and (n-p-1-m). Conclusion Ho is rejected if F > F (α, m, n-p-1-m) or p-value < α (typically use the alpha value of 0.05).

B. White test

White test is non linearity detection test developed from neural models network raised by [7]. This test is included in the test group of type Lagrange Multiplier (LM). Hypothesis testing used in the test are the nonlinearitas:

$H_0 : f(X)$ is a linear function of the X or the linear model

$H_1 : f(X)$ is a nonlinear function of the X or the nonlinear model

H_0 is rejected, which means non-linear model is appropriate, if the value of the F test meets namely the rejection region

$$F > F_{\alpha;(df_1, df_2)} \text{ atau } p\text{-}value < \alpha$$

The following steps in the White test by [3]:

1. Regression of Y_t on $1, x_1, x_2, ..., x_p$, calculate the residual value $\hat{u}_t$ and calculate residual sum of squares:
$$SSR_0 = \sum \hat{u}_t^2 \tag{8}$$
2. Regression of Y_t on $1, x_1, x_2, ..., x_p$, m additional predictors so calculate residual $\hat{v}_t$ and calculate residual sum of squares:
$$SSR_1 = \sum \hat{v}_t^2 \tag{9}$$
3. Calculate F test score
$$F = \frac{\left(SSR_0 - SSR_1\right)/m}{SSR_1/\left(n - p - 1 - m\right)} \tag{10}$$
Where:

m: additional predictors

p: early predictors

n: number of data in used

4. Based on the hypothesis of linearity, shows F test values approaching F distribution with degrees of freedom of m and (n-p-1-m). Conclusion Ho is rejected if F > F (α, m, n-p-1-m) or p-value < α (typically use the alpha value of 0.05).

C. Terasvirta test

Terasvirta test included in the group Lagrange Multiplier (LM) test with a Taylor expansion approach that uses a test statistic χ^2 with degrees v. Terasvirta test procedure is described as follows [3]:

1. Regression of Y_t on $1, x_1, x_2, ..., x_p$, and calculate the residual value $\hat{u}_t$.
2. Regression of Y_t on $1, x_1, x_2, ..., x_p$, and m additional predictors which is the result of Taylor expansion approach.
3. Calculate the coefficient of determination (R^2) and regression in the previous step.
4. Calculate statistics test $\chi^2 = nR^2$ with n is number of data. Hypothesis testing used in the test are the nonlinearitas:

   $H_0 : f(X)$ is a linear function of the X or the linear model

   $H_1 : f(X)$ is a nonlinear function of the X or the nonlinear model
5. Based on the hypothesis of linearity, shows χ^2 test values approaching χ_V^2 distribution. Conclusion Ho is rejected if p-value from χ^2 test values < α (typically use the alpha value of 0.05).

IV. METHODOLOGY

Data used in this study are secondary data the number of foreign tourists at the airport Juanda obtained from BPS. Data used in this study is the monthly data, the period to be examined is January 2000 to December 2015. This study begins with a description of the data that will be used to determine the amount of data to be used as well as other descriptions of the data. Then the data will be plotted using a time series plot to show data on the number of foreign tourists pattern at Juanda airport and final testing will be performed on the data using nonlinear three nonlinearitas test is Ramsey's RESET test, White test adn Terasvirta test. This research using minitab program to descriptive data and time series plot, whereas for the non linearity test using the assistance program R.

V. RESULTS AND DISCUSSION

The first step in this research was to determine the amount of data on the number of foreign tourists at the airport Juanda started January 2000 to December 2015. The following description is shown in the table data to be used:

TABEL 1. DESCRIPTIVE STATISTICS

Variable	Total count	Mean	SE Mean	St Dev
Juanda	192	11923	330	4569

Based on Table 1, indicated that the data used in this study as many as 192 data with mean 11923 and stardard deviation 4569. Since determining much of the data used, the next step is to see patterns in the data on the number of foreign tourists. then be shown a pattern of data using time series plot in the figure below:

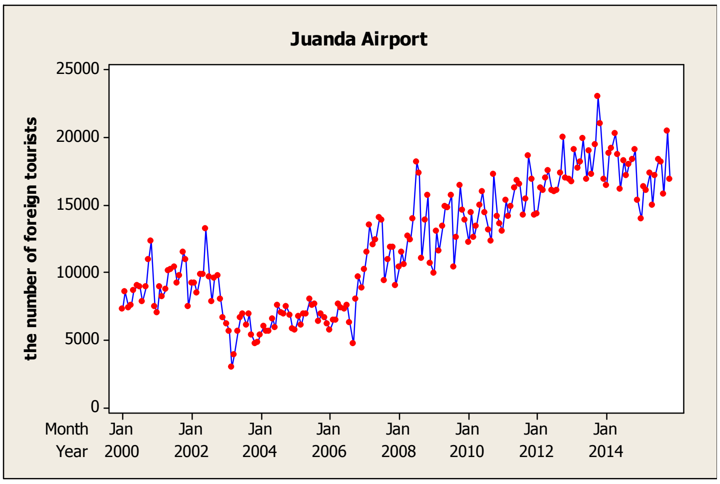

FIGURE 1. TIME SERIES PLOT OF JUANDA

Shown in Figure 1, data on the number of foreign tourists have a pattern that is up and down. The next will be tested for nonlinearitas because such data is not always a linear pattern. before conducting the test, will be determined in advance time series model to be used in testing. the model used in this study is a model AR (1), this model is a time series model with a univariate predictor variables. The following models of the AR (1) to be used in this study:

$$Y_t = Y_{t-1} \tag{11}$$

after determining the models to be tested, last step the model will be tested using three test program nonlinearitas using R. after the test is done using R obtained the following results:

```
#packages in used
library(lmtest)
library(tseries)

#Load Data
data=read.csv("d://wisman.csv",sep=";",header=T)
attach(data)

#Ramsey's RESET Test
model      = Yt~Yt.1
reset.test = reset(model, type='regressor',data=data)
reset.test$p.value

#Terasvirta Test
teras.test=terasvirta.test(x=Yt.1, y=Yt, type = "F",scale = T)
teras.test$p.value

#White Test
Whi.test=white.test(x=Yt.1, y=Yt, type = "Chisq",scale = T)
Whi.test$p.value
```

FIGURE 2. SYNTAX NONLINEARITY TEST

The syntax is obtained based on [2], with some simple changes. After the test is done using R obtained the following results:

```
> #Ramsey's RESET Test
> model      = Yt~Yt.1
> reset.test = reset(model, type='regressor',data=data)
> reset.test$p.value
[1] 0.01006504
>
>
> #Terasvirta Test
> teras.test=terasvirta.test(x=Yt.1, y=Yt, type = "F",scale = T)
> teras.test$p.value
[1] 0.009820545
>
>
> #White Test
> Whi.test=white.test(x=Yt.1, y=Yt, type = "Chisq",scale = T)
> Whi.test$p.value
[1] 0.007855382
```

FIGURE 3. RESULT NONLINEARITY TEST

Syntax in R is based on the steps [1], [7] and [3]. Based on the results of running using the R found that the three test produces a value less than the p-value of 0.05.Ramsey's RESET test the values obtained data on the number of foreign tourists at the airport juanda of 0.01006504, with a p-value of 0.05 so that it can be seen that the number of foreign tourists at the airport juanda smaller than the p-value. White test the values obtained data on the number of foreign tourists at the airport juanda of 0.009820545, with a p-value of 0.05 so that it can be seen that the number of foreign tourists at the airport juanda smaller than the p-value. Terasvirta test the values obtained data on the number of foreign tourists at the airport juanda of 0.007855382, with a p-value of 0.05 so that it can be seen that the number of foreign tourists at the airport juanda smaller than the p-value.

VI. CONCLUSIONS

Based on the results and discussions can be concluded that the time series data, especially data on the number of foreign tourists at Juanda airport is a nonlinear model. Because it is based on three trials showed nonlinearity p-value less than 0.05. as shown in the table below:

	Ramsey's RESET test	White test	Terasvirta test
p-value	0.01006504	0.009820545	0.007855382

After finding out that the time series data can be non-linear form, this data can be used for regression semiparametric or nonparametric regression.

Analyzing Of Bank Performance Level Using RGEC And Mamdani Fuzzy System Implemented With Graphical User Interface

Rani Mita Sari[1], Agus Maman Abadi[2]
[1,2]Department of Mathematics, Yogyakarta State University, Indonesia
rani.mitasari@yahoo.co.id

***Abstract*—**Banking industry has become an integral part in operating economic activities in every country. It is one of the most vibrant and growing industries of Indonesia. Analyzing of bank's performance helps them to evaluate and improve their weaker area and to know how far they have satisfied their customer. It also becomes one of the customers' considerations to choice their bank. This research is aimed at explaining how to apply Mamdani fuzzy system to determine the performance of banks in Indonesia and the system is implemented by using Graphical User Interface (GUI). The other aim of this research is to determine the accuracy of bank's performance using Mamdani fuzzy system. The first step is to determine the bank performance that is measured by using RGEC approach (Risk Profile, Good Corporate Governance, Earnings, Capital). The ratios that are used are Non Performing Loan (NPL), Loan to Deposit Ratio (LDR), Return on Assets (ROA), Return on Equity (ROE), Net Interest Margin (NIM), and Capital Adequacy Ratio (CAR). This research is quantitative descriptive research using secondary data. This research uses 109 banks' data with three years period. The data are divided into two parts which 87 banks are for training data and 22 banks are for testing data. The fuzzy system that is used is Mamdani method and we use the centroid method in defuzzification process. Then, the result of fuzzy system is implemented by using Graphical User Interface (GUI).The accuracy of the Mamdani fuzzy system for data training in 2011, 2012, 2013 is respectively 86.2%, 83.9%, 91.95%. The accuracy of testing data in 2011, 2012, 2013 is respectively 95.45%,100%, 100%. It means that the Mamdani fuzzy system can be applied to classify the bank performance in Indonesia.

Keywords: *bank performance, Graphical User Interface, RGEC, Mamdani fuzzy system.*

I. INTRODUCTION

Bank is an institution collecting fund from people in the form of deposit and distributing it to people in the form of credit in order to increase the their quality life. Banking industry has a vital role in improving the economic condition of a country [1]. It is because most of the life sectors related to finances need the banking service so that bank becomes the core of a country's economic matters.

Based on that statement, it is needed to know the performance of banks. Knowing the banks' performance is aimed at keeping the economic stability and becoming the customers' consideration in choosing a bank. Besides, it can be used by Bank Indonesia to supervise a bank. The method used to assess the performance of banks in Indonesia is RGEC method. This method contains the assessment of general bank performance level with the risk approach including the assessment of four factors. They are Risk Profile, Good Coorporate Governance, Earning, dan Capital [2].

There are several researches about banks performance that have been done which one of them is by Nadia Iffatul Ulya using RGEC method with Man-Whitney to compare 15 conventional banks to Islamic banks [3]. While, Uddin and Bristy use squared correlation coefficient method (r^2) to analyze five commercial banks in Bangladesh [4]. Then, Shen and Tzeng use DRSA (dominance-based rough set approach) method with Neural Network in the application of financial condition prediction of bank in Taiwan [5]. Nur Artyka uses RGEC method to assess the performance of PT. Bank Rakyat Indonesia in 2011-2013 [6]. Moreover, Anis Ulfah Mustaqim analyzes the performance of 107 banks in Indonesia by using CAMEL method with Mamdani fuzzy logic [7]. The last is a research conducted by Rani Mita Sari classifying the performances of banks in Indonesia with RGEC method and zero-order Sugeno fuzzy [8].

Fuzzy system can be interpreted as a complete linguistic description (the rule of fuzzy: if-then) that is about a process that can be combined into a model [9]. The phase of fuzzy system is fuzzification, fuzzy inference, and defuzzification. The fuzzy system can be applied into many kinds of field, such as: medical diagnose, control algorithm, decision supporting system, economic, technique, environment, psychology, and many more [10]. Mamdani's fuzzy inference method was among the first control systems built using fuzzy set theory. This research uses fuzzy system with Mamdani inference and and centroid defuzzification as the aids to make a decision in assessing the bank performance in Indonesia. Mamdani method is simple inference method because it has easy calculation and comprehension level [11]. Graphical User Interface (GUI) is used as the connector between the users and fuzzy system that is built to ease the users in operating it.

II. METHODS

The data is obtained from the file of Bank Indonesia and the website of Financial Service Authority. There are 109 banks' data that are collected. The data of those banking names are then given a code like 1, 2, 3,…,109 as the substitute of the names of the researched banks. This researched is conducted for three years so that it is collected 327 banks' data. The RGEC factor is only limited by the risk profile, earnings, and capital. The good corporate governance (GCG) factor is not analyzed because it is qualitative research done by the bank itself (self-assessment) and it is because there is not any data for that factor in the file of Bank Indonesia. The steps of the research are shown by Figure 1 as follows:

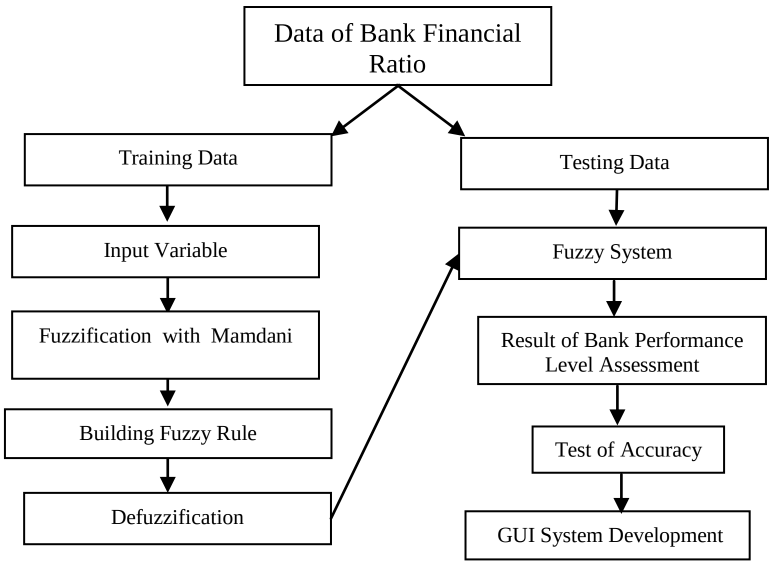

FIGURE 1. THE STEPS OF BANK PERFORMANCE LEVEL ASSESSMENT USING MAMDANI FUZZY SYSTEM

The first is looking for the ratio to measure the factors used in the RGEC method. Risk profile factor uses two ratio indicators i.e. Non Performing Loan (NPL) and Loan to Deposit Ratio (LDR). The earnings factor uses the ratio of Return on Assets (ROA), Return on Equity (ROE), Net Interest Margin (NIM). Capital Adequacy Ratio (CAR) is used to analyze the Capital factor. The determination of NPL and LDR ranking can be seen on the Table 1.

TABLE 1. MATRIX OF RANKING DETERMINATION CRITERIA OF NPL AND LDR

Ranking	Information	NPL Criteria	LDR Criteria
1	Very good	NPL < 2%	LDR ≤ 75%
2	Good	2% ≤ NPL < 3,5%	75% < LDR ≤ 85%
3	Good enough	3,5% ≤ NPL < 5%	85% < LDR ≤ 100%
4	Less than good	5% ≤ NPL ≤ 8%	100% < LDR ≤ 120%
5	Not good	NPL > 8%	LDR > 120%

SOURCE : BUKU LAPORAN KEUANGAN [12] AND SURAT EDARAN BANK INDONESIAI [13]

The matrix of ranking determination criteria of Return on Assets (ROA) ratio, Return on Equity (ROE) ratio, and Net Interest Margin (NIM) is shown on the Table 2.

TABLE 2. MATRIX OF RANKING DETERMINATION CRITERIA OF ROE AND NIM

Ranking	Information	ROA Criteria	ROE Criteria	NIM Criteria
1	Very good	ROA > 1,5%	ROE > 20%	NIM > 5%
2	Good	1,25% < ROA ≤ 1,5%	12,51% ≤ ROE ≤ 20%	2.01% ≤ NIM ≤ 5%
3	Good enough	0,5% < ROA ≤ 1,25%	5,01% ≤ ROE ≤ 12,5%	1.51% ≤ NIM ≤ 2%
4	Less than good	0% < ROA ≤ 0,5%	0% ≤ ROE ≤ 5%	0% ≤ NIM ≤ 1.49%
5	Not good	ROA ≤ 0%	ROE < 0%	NIM < 0%

SOURCE: LAMPIRAN II SURAT EDARAN BANK INDONESIA [14] AND SURAT EDARAN BANK INDONESIA [13]

Standart rasio Capital Adequacy Ratio(CAR) can be seen on the Table 3.

TABLE 3. MATRIX OF RANKING DETERMINATION CRITERIA OF CAPITALIZATION

Ranking	Information	Criteria
1	Very good	KPMM > 12%
2	Good	9% < KPMM ≤ 12%
3	Good enough	8% < KPMM ≤ 9%
4	Less than good	6% < KPMM ≤ 8%
5	Not good	KPMM ≤ 6%

SOURCE : SURAT EDARAN BANK INDONESIA [13]

III. RESULTS AND DICUSSION

The first step in assessing the bank performance is looking for each bank's performance by using RGEC method. The performance level of a bank is known through the composite level it has, using the criteria that has been determined on the Table 1, Table 2, and Table 3. After the whole ratio data are collected, the next step is classifying each RGEC ratio into several composite ranks so that it can be determined its own score.

For example is the financial ratio data of the bank code 3 in 2011. The ratio can be classified into suitable composite ranking as it reflected on the Table 4.

TABLE 4. RATIO COMPOSITE RANKING OF BANK CODE 3 YEAR OF 2011

RGEC Ratio	Ratio Value	Composit Ranking
NPL	3,55	3 (very good)
LDR	65,79	1 (very good)
ROA	1,39	2 (very good)
ROE	11,39	3 (very good)
NIM	4,54	2 (very good)
CAR	16,39	1 (very good)

After the result of performance level ranking determination on each RGEC factor is gained, the score is defined to determine the final composite ranking of a bank.

TABLE 5. PERFORMANCE LEVEL OF BANK CODE 3 YEAR OF 2013

RGEC Ratio	Composite Ranking	Score
NPL	3	3
LDR	1	5
ROA	2	4
ROE	3	3
NIM	2	4
CAR	1	5
Total of Score		24

The score total gained by bank code 3 is 24. It means that the bank can be categorized into composite ranking 2 or it shows that the condition of bank 3 is good in general so that the bank is assumed to be able to face the significant negative impacts form the change of business condition or the other external factors.

Based on that performance assessment, the next step can be done that is building the fuzzy system. The followings are the steps of building the Mamdani fuzzy system.

A. Identifying the Set of Universal (U) on the Input and Output

Universal set is the value allowed in fuzzy system operation. There are 87 training data that are used with three years period so that the total of training data is 261 data. Here are the universal set on the input variable: $U_{\text{NPL}} = [0, 13]$, $U_{\text{LDR}} = [0, 621]$, $U_{\text{ROA}} = [-2, 8]$, $U_{\text{ROE}} = [-20, 144]$, $U_{\text{NIM}} = [-2, 21]$, and $U_{\text{CAR}} = [0, 182]$. The universal set on the output is $U_{\text{output}} = [0\ 31]$.

B. Identifying Fuzzy Set on the Input and Output

In this step, the clear set will be transformed into fuzzy set. The process is named fuzzification process. The fuzzy set is transformed by using affiliation function. The affiliation function used on the input of this research is the affiliation function of shoulder curve approach with the combination of affiliation function of triangle and trapezium.

Input variable can be defined into five fuzzy set with the affiliation function of shoulder curve approach. Fuzzy set for bank that have composite ranking 1 given a code SS, composite ranking 2 given code S, composite ranking 3 given code CS, composite ranking 4 given code KS, and composite ranking 5 given code TS. The equation shoulder curve on the NPL and LDR ratio is as follows:

$$\mu_{\text{NPL}_{\text{SS}}}(x) = \begin{cases} 1 & ; 0 \le x \le 1{,}5 \\ -x + 2{,}5 & ; 1{,}5 \le x \le 2{,}5 \\ 0 & ; x \ge 2{,}5 \end{cases}$$

$$\mu_{\text{NPL}_{\text{S}}}(x) = \begin{cases} 1 & ; x \le 1{,}5 \text{ or } x \ge 4{,}5 \\ x - 1{,}5 & ; 1{,}5 \le x \le 2{,}5 \\ \frac{4{,}5 - x}{2} & ; 2{,}5 \le x \le 4{,}5 \end{cases}$$

$$\mu_{\text{NPL}_{\text{CS}}}(x) = \begin{cases} 0 & ; x \le 2{,}5 \text{ or } x \ge 5{,}5 \\ \frac{x - 2{,}5}{2} & ; 2{,}5 \le x \le 4{,}5 \\ 5{,}5 - x & ; 4{,}5 \le x \le 5{,}5 \end{cases}$$

$$\mu_{\text{NPL}_{\text{KS}}}(x) = \begin{cases} 0 & ; x \le 4{,}5 \text{ or } x \ge 10{,}5 \\ x - 4{,}5 & ; 4{,}5 \le x \le 5{,}5 \\ \frac{10{,}5 - x}{5} & ; 5{,}5 \le x \le 10{,}5 \end{cases}$$

$$\mu_{\text{NPL}_{\text{TS}}} = \begin{cases} 0 & ; x \le 5{,}5 \\ \dfrac{x - 5{,}5}{5} & ; 5{,}5 \le x \le 10{,}5 \\ 1 & ; 10{,}5 \le x \le 13 \end{cases}$$

and

$$\mu_{\text{LDR}_{\text{SS}}}(x) = \begin{cases} 1 & ; 0 \le x \le 70 \\ \dfrac{80 - x}{10} & ; 70 \le x \le 80 \\ 0 & ; x \ge 80 \end{cases}$$

$$\mu_{\text{LDR}_{\text{S}}}(x) = \begin{cases} 0 & ; x \le 70 \text{ or } x \ge 90 \\ \dfrac{x - 70}{10} & ; 70 \le x \le 80 \\ \dfrac{90 - x}{10} & ; 80 \le x \le 90 \end{cases}$$

$$\mu_{\text{LDR}_{\text{CS}}}(x) = \begin{cases} 0 & ; x \le 80 \text{ or } x \ge 110 \\ \frac{x - 80}{10} & ; 80 \le x \le 90 \\ \frac{110 - x}{20} & ; 90 \le x \le 110 \end{cases}$$

$$\mu_{\text{LDR}_{\text{KS}}}(x) = \begin{cases} 0 & ; x \le 90 \text{ or } x \ge 130 \\ \frac{x - 90}{20} & ; 90 \le x \le 110 \\ \frac{130 - x}{20} & ; 110 \le x \le 130 \end{cases}$$

$$\mu_{\text{LDR}_{\text{TS}}}(x) = \begin{cases} 0 & ; x \le 110 \\ \frac{x - 110}{20} & ; 110 \le x \le 130 \\ 1 & ; 130 \le x \le 621 \end{cases}$$

The representation of fuzzy set on the input variable of NPL ratio and LDR ratio can be seen on the Figure 2 and Figure 3.

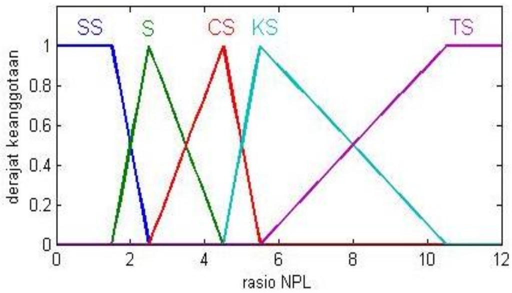

FIGURE 2. FUZZY SET IN NPL VARIABLE

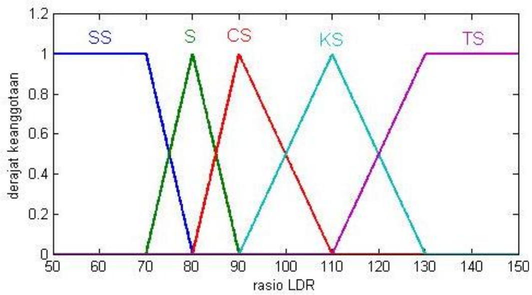

FIGURE 3. FUZZY SET IN LDR VARIABLE

The shoulder curve equation on the ROA ratio and ROE ratio is as follows:

$$\mu_{\text{ROA SS}} = \begin{cases} 0 & ; x \le 1{,}4 \\ \dfrac{x - 1{,}4}{0{,}2} & ; 1{,}4 \le x \le 1{,}6 \\ 0 & ; 1{,}6 \le x \le 8 \end{cases}$$

$$\mu_{\text{ROE SS}}(x) = \begin{cases} 0 & ; x \le 17{,}5 \\ \dfrac{x - 17{,}5}{5} & ; 17{,}5 \le x \le 22{,}5 \\ 1 & ; 22{,}5 \le x \le 143 \end{cases}$$

$$\mu_{ROA\ S}(x) = \begin{cases} 0 & ; x \le 1{,}1 \text{ or } x \ge 1{,}6 \\ \dfrac{x - 1{,}1}{0{,}3} & ; 1{,}1 \le x \le 1{,}4 \\ \dfrac{1{,}6 - x}{0{,}2} & ; 1{,}4 \le x \le 1{,}6 \end{cases}$$

$$\mu_{ROA\ CS}(x) = \begin{cases} 0 & ; x \le -0{,}1 \text{ or } x \ge 1{,}4 \\ \frac{x+0{,}1}{1{,}2} & ; -0{,}1 \le x \le 1{,}1 \\ \frac{1{,}4-x}{0{,}3} & ; 1{,}1 \le x \le 1{,}4 \end{cases}$$

$$\mu_{ROA\ KS}(x) = \begin{cases} 0 & ; x \le -0{,}2 \text{ or } x \ge 1{,}1 \\ \frac{x+0{,}2}{0{,}1} & ; -0{,}2 \le x \le -0{,}1 \\ \frac{1{,}1-x}{1{,}2} & ; -0{,}1 \le x \le 1{,}1 \end{cases}$$

$$\mu_{ROA_{TS}}(x) = \begin{cases} 1 & ; -2 \le x \le -0{,}2 \\ \frac{-x-0{,}1}{0{,}1} & ; -0{,}2 \le x \le -0{,}1 \\ 0 & ; x \ge -0{,}1 \end{cases}$$

And

$$\mu_{ROE_S}(x) = \begin{cases} 0 & ; x \le 7{,}5 \text{ or } x \ge 22{,}5 \\ \frac{x-7{,}5}{10} & ; 7{,}5 \le x \le 17{,}5 \\ \frac{22{,}5-x}{5} & ; 17{,}5 \le x \le 22{,}5 \end{cases}$$

$$\mu_{ROE_{CS}}(x) = \begin{cases} 0 & ; x \le 2{,}5 \text{ or } x \ge 17{,}5 \\ \frac{x-2{,}5}{5} & ; 2{,}5 \le x \le 7{,}5 \\ \frac{17{,}5-x}{10} & ; 7{,}5 \le x \le 17{,}5 \end{cases}$$

$$\mu_{ROE_{KS}}(x) = \begin{cases} 0 & ; x \le -2{,}5 \text{ or } x \ge 7{,}5 \\ \frac{x+2{,}5}{5} & ; -2{,}5 \le x \le 2{,}5 \\ \frac{7{,}5-x}{5} & ; 2{,}5 \le x \le 7{,}5 \end{cases}$$

$$\mu_{ROE_{TS}}(x) = \begin{cases} 1 & ; -20 \le x \le -2{,}5 \\ \frac{2{,}5-x}{5} & ; -2{,}5 \le x \le 2{,}5 \\ 0 & ; x \ge 2{,}5 \end{cases}$$

The representation of fuzzy set on the input variable of ROE ratio and ROE ratio can be seen on the Figure 4 and Figure 5.

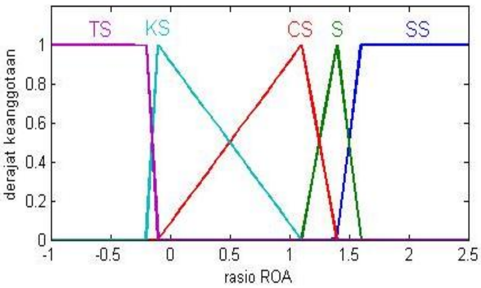

FIGURE 4. FUZZY SET IN ROA VARIABLE

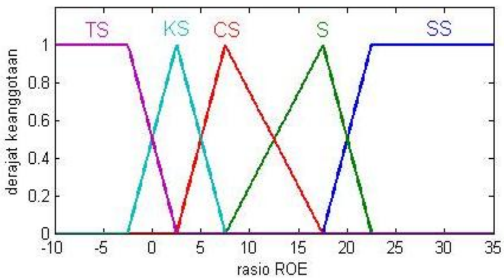

FIGURE 5. FUZZY SET IN ROE VARIABLE

The shoulder curve equation on the ROA ratio and ROE ratio is as follows:

$$\mu_{NIM_{SS}}(x) = \begin{cases} 0 & ; x \le 2{,}25 \\ \frac{x-2{,}25}{5{,}5} & ; 2{,}25 \le x \le 7{,}75 \\ 1 & ; 7{,}75 \le x \le 21 \end{cases}$$

$$\mu_{NIM_S}(x) = \begin{cases} 0 & ; x \le 1{,}75 \text{ or } x \ge 7{,}75 \\ \dfrac{x - 1{,}75}{0{,}5} & ; 1{,}75 \le x \le 2{,}25 \\ \dfrac{7{,}75 - x}{5{,}5} & ; 2{,}25 \le x \le 7{,}75 \end{cases}$$

$$\mu_{NIM_{CS}}(x) = \begin{cases} 0 & ; x \le 1{,}25 \text{ or } x \ge 2{,}25 \\ \dfrac{x - 1{,}25}{0{,}5} & ; 1{,}25 \le x \le 1{,}75 \\ \dfrac{2{,}25 - x}{0{,}5} & ; 1{,}75 \le x \le 2{,}25 \end{cases}$$

$$\mu_{NIM_{KS}}(x) = \begin{cases} 0 & ; x \le -1{,}25 \text{ or } x \ge 1{,}75 \\ \frac{x+1{,}25}{2{,}5} & ; -1{,}25 \le x \le 1{,}25 \\ \frac{1{,}75-x}{0{,}5} & ; 1{,}25 \le x \le 1{,}75 \end{cases}$$

And

$$\mu_{CAR\ SS}(x) = \begin{cases} 0 & ; x \le 9{,}5 \\ \dfrac{x - 9{,}5}{5} & ; 9{,}5 \le x \le 14{,}5 \\ 1 & ; 14{,}5 \le x \le 182 \end{cases}$$

$$\mu_{CAR\ S}(x) = \begin{cases} 0 & ; x \le 8{,}5 \text{ or } x \ge 14{,}5 \\ x - 8{,}5 & ; 8{,}5 \le x \le 9{,}5 \\ \dfrac{14{,}5 - x}{5} & ; 9{,}5 \le x \le 14{,}5 \end{cases}$$

$$\mu_{CAR\ CS}(x) = \begin{cases} 0 & ; x \le 7{,}5 \text{ or } x \ge 9{,}5 \\ x - 7{,}5 & ; 7{,}5 \le x \le 8{,}5 \\ 9{,}5 - x & ; 8{,}5 \le x \le 9{,}5 \end{cases}$$

$$\mu_{CAR\ KS}(x) = \begin{cases} 0 & ; x \le 4{,}5 \text{ or } x \ge 8{,}5 \\ \dfrac{x - 4{,}5}{3} & ; 4{,}5 \le x \le 7{,}5 \\ 8{,}5 - x & ; 7{,}5 \le x \le 8{,}5 \end{cases}$$

$$\mu_{CAR\ TS}(x) = \begin{cases} 1 & ; 0 \le x \le 4{,}5 \\ \dfrac{7{,}5 - x}{3} & ; 4{,}5 \le x \le 7{,}5 \\ 0 & ; x \ge 7{,}5 \end{cases}$$

$$\mu_{NIM_{TS}}(x) = \begin{cases} 1 & ; -2 \le x \le -1{,}25 \\ \frac{1{,}25 - x}{2{,}5} & ; -1{,}25 \le x \le 1{,}25 \\ 0 & ;\ x \ge 1{,}25 \end{cases}$$

The representation of fuzzy set on the input variable of ROE ratio and ROE ratio can be seen on the Figure 6 and Figure 7.

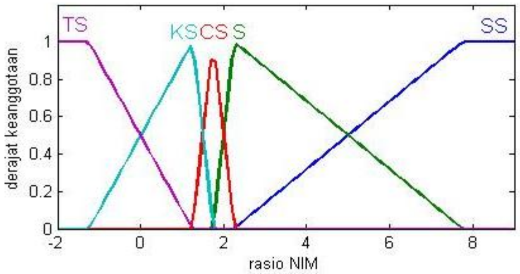

FIGURE 6. FUZZY SET IN INPUT VARIABLE

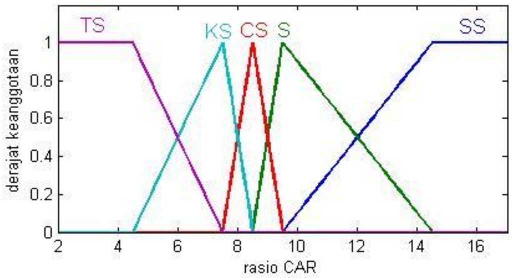

FIGURE 7. FUZZY SET IN INPUT VARIABLE

Output variable is also represented by shoulder curve approach. The value of RGEC ratio has output not good (TS), less than good (KS), good enough (CS), sehat (S), dan very good (SS) with the affiliation function as follows:

$$\mu_{output_{SS}}(x) = \begin{cases} 0 & ; x \le 24{,}5 \\ \dfrac{x - 24{,}5}{6} & ; 24{,}5 \le x \le 30{,}5 \\ 1 & ; 30{,}5 \le x \le 31 \end{cases}$$

$$\mu_{output_{S}}(x) = \begin{cases} 0 & ; x \le 18{,}5 \text{ or } x \ge 30{,}5 \\ \dfrac{x - 18{,}5}{6} & ; 18{,}5 \le x \le 24{,}5 \\ \dfrac{30{,}5 - x}{6} & ; 24{,}5 \le x \le 30{,}5 \end{cases}$$

$$\mu_{output_{CS}}(x) = \begin{cases} 0 & ; x \le 9{,}5 \text{ or } x \ge 24{,}5 \\ \dfrac{x - 9{,}5}{9} & ; 9{,}5 \le x \le 18{,}5 \\ \dfrac{24{,}5 - x}{6} & ; 18{,}5 \le x \le 24{,}5 \end{cases}$$

$$\mu_{output_{KS}}(x) = \begin{cases} 0 & ; x \le 3{,}5 \text{ or } x \ge 18{,}5 \\ \dfrac{x - 3{,}5}{6} & ; 3{,}5 \le x \le 9{,}5 \\ \dfrac{18{,}5 - x}{9} & ; 9{,}5 \le x \le 18{,}5 \end{cases}$$

$$\mu_{output_{TS}}(x) = \begin{cases} 1 & ; 0 \le x \le 3{,}5 \\ \dfrac{9{,}5 - x}{6} & ; 3{,}5 \le x \le 9{,}5 \\ 0 & ;\ x \ge 9{,}5 \end{cases}$$

The fuzzy set on the output variable can be seen on the Figure 8.

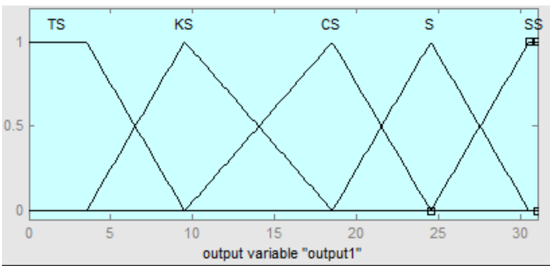

FIGURE 8. FUZZY SET IN OUTPUT VARIABLE

C. Determining Fuzzy Rule

The performance assessment result used in determining fuzzy rule comes form the total of training data of which the total is 261. The fuzzy rule that has been made is sequenced and selected. If there are several same rules, then it is only one that is chosen whereas the other ones are eliminated. The performance level of bank code 3 with the RGEC method has good output. For example is the bank code 3 in 2011 of which the NPL ratio value is 3,55, LDR ratio value is 65,79, ROA ratio value is 1,39, ROE ratio value is 11.39, NIM ratio value is 4,54, and CAR ratio value is 16,39. Then, the fuzzy rule is looked for based on those data. That ratio value is reckoned as *x* value. Based on the five fuzzy set defined on the NPL variable, the NPL affiliation degree can be then known. The function of combination basic operation is used to choose the biggest affiliation degree of those five affiliation degree [15].

$$\begin{aligned} \mu A\cup B\ (x) &= \max[\mu A(x), \mu A(x)], \forall x \in U \qquad (1)\\ &= \max[0; 0{,}475; 0{,}525; 0; 0]\\ &= 0{,}525. \end{aligned}$$

The NPL affiliation degree of bank code 112 in 2011 is 0,525 so that the NPL ratio can be classified into the set of fuzzy NPL_3 or good enough. Do the same thing to the other ratio factors so that it will be created a fuzzy rule i.e. "If NPL is NPL_3 (good enough) and LDR is LDR_1 (very good) and ROA is ROA_2 (good) and ROE is ROE_3 (good enough) and NIM is NIM_2 (good) and CAR is CAR_1 (very good), then the result of bank assessment is good. Furthermore, do the same thing to 260 other banks so that it will be created 141 fuzzy rules as follows.

1 If NPL is VERY GOOD and LDR is VERY GOOD and ROA is VERY GOOD and ROE is VERY GOOD and NIM is VERY GOOD and CAR is VERY GOOD so that the bank assessment is VERY GOOD"

2 If NPL is VERY GOOD and LDR is VERY GOOD and ROA is VERY GOOD and ROE is VERY GOOD and NIM is VERY GOOD and CAR is GOOD so that the bank assessment is VERY GOOD"

3 If NPL is VERY GOOD and LDR is VERY GOOD and ROA is VERY GOOD and ROE is VERY GOOD and NIM is GOOD ENOUGH and CAR is GOOD so that the bank assessment is VERY GOOD"

. .
. .
. .

115 If NPL is GOOD ENOUGH and LDR is VERY GOOD and ROA is SEHAT and ROE is GOOD ENOUGH and NIM is GOOD and CAR is VERY GOOD so that the bank assessment is GOOD"

. .
. .
. .

141 If NPL is LESS THAN GOOD and LDR is GOOD and ROA is NOT GOOD and ROE is NOT GOOD and NIM is VERY GOOD and CAR is GOOD so that the bank assessment is GOOD ENOUGH"

D. Fuzzy Sytsem Inference with Mamdani Method

Mamadani method or *min-max inferencing* uses implication function min or AND and rule aggregation max or OR. The aggregation of fuzzy rule can be searched by using the formula as follows.

$$\mu_{B^k}(y)=\max_k[\min[\mu A_1^k(xi),\mu A_2^k(xj)]] \qquad (2)$$

For k = 1,2, . . n, $A_1^k$and A_2^kstates that antecendent pair fuzzy set is number- k, and B^k is a consequent fuzzy set number- k. [16]. For example, bank code 3 has been looked for its own biggest affiliation degree. That affiliation degree forms a fuzzy rule. According to that rule, it can be looked its implication value. The implication value can be looked by determining the minimum value using piece basic operation that is reflected by the Equation (3) [15].

$$\begin{aligned} \mu A\cap B\ (x) &= \min[\mu A(x), \mu A(x)], \forall x\in U \qquad (3)\\ &=\min(0{,}525;1; 0{,}967; 0{,}611; 0{,}583;1)\\ &= 0{,}525 \end{aligned}$$

TABLE 6. IMPLICATION FUCNTION RESULT OF BANK CODE 3 IN 2011

Rules	NPL	LDR	ROA	ROE	NIM	CAR	Implikacation α_n
1	0,525	1	0,967	0,611	0,583	1	0,525
2	0,525	1	0,967	0,611	0,583	0	0
..	...	...	...	...	...	...	...
141	0	0	0	0	0,416	0	0

By using the equation (2), it is known that the aggregation value of bank code 3 in 2011 is 0,525. The rules composition result for the bank code 3 in 2011 is shown by the FIGURE 3.

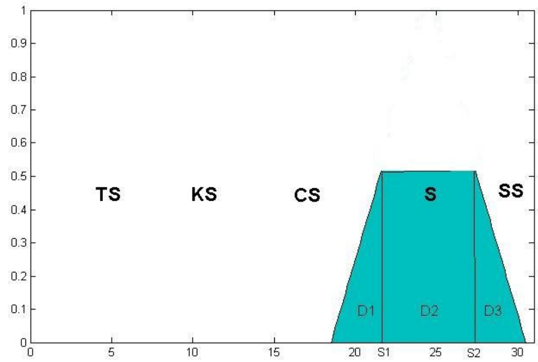

FIGURE 9. The Area of Rules Composition Result of Bank Code 3

Based on that calculation, it is gained that the affiliation function for the rules composition result of bank code 3 is.

$$\mu(x) = \begin{cases} \frac{x-18,5}{6};\ 18,5 \le x \le 21,65 \\ 0,525;\quad 21,65 \le x \le 27,35 \\ \frac{30,5-x}{6}; 27,35 \le x \le 30,5 \end{cases} \tag{4}$$

E. Fuzzy System Defuzzification

Deffuzifiaction is aimed at gaining the clear value on the output. The calculation of Centroid defuzzification can be done by using the equation (5) as follows.

$$D^* = \frac{\int_x \ x\,\mu_B(x)\ dx}{\int_x \ \mu_B(x)\ dx} \tag{5}$$

Then, the Equation (4) is gotten defuzzification with the Equation (5)

$$D^* = \frac{\int_{18,5}^{21,65} x\left(\frac{x-18,5}{6}\right)dx + \int_{21,65}^{27,35} x(0,525)dx + \int_{27,35}^{30,5} x\left(\frac{30,5-x}{6}\right)dx}{\int_{18,5}^{21,65}\left(\frac{x-18,5}{6}\right)dx + \int_{21,65}^{27,35}(0,525)dx + \int_{27,35}^{30,5}\left(\frac{30,5-x}{6}\right)dx}$$

$$= \frac{\frac{1}{6}\left[\frac{x^3}{3} - 9,25x^2\right]_{18,5}^{21,65} + 0,525\left[\frac{x^2}{2}\right]_{21,65}^{27,35} + \frac{1}{6}\left[15,25x^2 - \frac{x^3}{3}\right]_{27,35}^{30,5}}{\frac{1}{6}\left[\frac{x^2}{2} - 18,5x\right]_{18,5}^{21,65} + 0,525[x]_{21,65}^{27,35} + \frac{1}{6}\left[30,5x - \frac{x^2}{2}\right]_{27,35}^{30,5}}$$

$$= \frac{113,83}{4,647} = 24,495$$

According to that calculation, the value of D*=24,495. It shows that the bank code 3 in 2011 can be categorized into *good* classification or composite ranking 2. Then, the steps having been done can be applied to the whole training and testing data and it will be gained the bank performance assessment result which uses Mamdani fuzzy system. The result of fuzzy system on the training data can be seen on the Table 7 and the testing data can be seen on the Table 8.

TABLE 7. THE RESULT OF FUZZY SYSTEM ON THE TRAINING DATA IN 2011

No	Bank Code	Assessment of Bank Performance		
		y*	***Fuzzy System***	**RGEC Assessment**
1	1	28,5	Very good	Very good
2	2	27,3	Very good	Very good
...	...	...	...	...
261	87	24,5	Good	Good

TABLE 8. THE RESULT OF FUZZY SYSTEM ON THE TESTING DATA IN 2011

No	Bank Code	Assessment of Bank Performance		
		y*	***Fuzzy System***	**RGEC Assessment**
1	88	28,8	Very good	Very good
2	89	28,5	Very good	Very good
...	...	...	...	...
66	109	24,5	Good	Good

The accuracy of the fuzzy system that has been created is then examined. The accuracy level is obtained from the comparison between the fuzzy system and the assessment with RGEC.

$$\text{Accuracy} = \frac{\text{Total of correct data}}{\text{Total of incorrect data}} \text{x}100\% \tag{6}$$

The correct data is the data producing the same assessment between the fuzzy system and the assessment of RGEC whereas the incorrect data is the data producing different assessment between the fuzzy system and the assessment with RGEC.

From the whole data compared, there are 12 incorrect assessments in 2011, 14 data that are not same in 2012, and seven incorrect data in 2013. The accuracy value of training data in 2011, 2012, 2013 is respectively 86,2%, 83,9% and 91,95%. In the testing data year of 2011, there is one data producing different assessment and in the year of 2012 and 2013, the whole data produce the same assessment between the fuzzy system and the assessment of RGEC. The accuracy value of testing data in 2011, 2012, 2013 is respectively 95,45%, 100% and 100%. Thus, the Mamdani fuzzy system having been created by using fuzzy inference system can be used to assess the performance of banks in Indonesia.

The fuzzy system is then implemented on the graphical user interface (GUI). It is aimed at easing the users in applying the fuzzy system having been created. The result of fuzzy system implementation having been created can be seen on the Figure 10.

FIGURE 10 . VIEWING FUZZY

The GUI system as it is shown above begins with processing the data inputted manually. The data which have been inputted into GUI system is then processed to be classified into composite ranking based on the rule having been made by Bank Indonesia. The assessment result of bank performance on the GUI represents the assessment on the fuzzy system having been created. It means that the assessment result and the level of GUI accuracy are the same with the result of the fuzzy system.

IV. Conclusion

A. Conclusion

The implementation of Mamdani fuzzy system in assessing the level of banks' performance in Indonesia starts form dividing the data into 87 banks as training and 22 banks as testing. In this research, the input that is used consisting of NPL, LDR, ROA, ROE, NIM and CAR which each of them use shoulder curve representation. The output result of fuzzy system shows that category of bank performance assessment level is not good, less than good, good enough, good dan very good. There are 141 rules having been created. Fuzzy inference is conducted by using Mamdani system with defuzzification is centroid method. The assessment result with Mamdani fuzzy system is then compared to the classification result based on the RGEC calculation. The result is used to calculate the system accuracy level. The last, the fuzzy system having been created is implemented with Grapichal User Interface (GUI).

The accuracy level gained on the fuzzy system for the training data in 2011, 2012, 2013 is 86,2%, 83,9% dan 91,95%. In the testing data, the accuracy value in 2011, 2012 dan 2013 is respectively 95,45%, 100% dan 100%. Based on the accuracy result that is gained, it can be concluded that Mamdani fuzzy system with Centroid defuzzification and that is implemented with Grapichal User Interface (GUI) is good to be used in assessing the performance level of banks in Indonesia.

B. Suggestions

The result of this research is still far from being perfect. Accordingly, it is still needed to add the newest relevant data and there are several things of the system that still have to be evaluated. The improvement and correction that can be done is adding the total of banking financial ratio data, adding the input variable total, conducting a test with various kinds of affiliation function for each input, inference system and fuzzy defuzzification system method as well as using the other inference methods such as zero-order Tsukamoto Sugeno and zero-order Sugeno.

Abstract— In research of epidemiology, structural equation modeling (SEM) has been become very popular, especially for latent variables. In SEM there are assumptions that must include the data should be normally distributed multivariate and a used large of data. For overcome these problems required the alternative approach of SEM based variance or partial least square (PLS). SEM-PLS does not require an assumption that a lot. In health sector randomization is not possible, because it concerns the lives of humans. So that assumptions independent can't be achieved. This can lead to imbalances covariates and selection bias. Therefore, to overcome these problems applied propensity score (PS). This method is a statistical analysis that can be used to analyze study design Non-Experimental where can't do randomization to treatment groups. Furthermore, as suggested new methods for handling selection bias is a marginal meanweighting through stratification (MMW-S). The analysis result obtained when using MMW-S is powerful because MMWS show strong reduction in of selection bias. The author uses an innovative method by using empirical data HIV/AIDS. Briefly using MMW-S with a predisposition, clinical manifestations, and opportunistic infection. And adherence to antiretroviral (ARV) as a confounding variable. The results showed that the method of MMW-S can removed bias more than 93.5%.

Keywords: *SEM-PLS, Propensity score, MMW-S, HIV/AIDS*

I. INTRODUCTION

Health problems are one of the factors that have an important role in creating quality human resources. In health, SEM has become a very popular method mainly used to examine the Latent variables. Non-Experimental studies or observational studies are empirical investigations of the effects caused by the treatment as randomized experiments Randomized Controlled Trials (RCT) is impossibble [1]. In general, RCT is very required in the research to the independence assumption so that the bias selection can be minimized. However, in the field of health research involving human, RCT is not always practicable. One method is suggested to be used for such problems is propensity score. Once the propensity score has been estimated in a given dataset, a data preprocessing procedure is performed to create comparability between study groups, it is referred to as pre-processing because it is performed before the final treatment effect is estimated, thus replicating the RCT by separating the study design stage from the outcomes analysis [2].

In general, this first entails stratifying the analytic sample into quantiles of the propensity score, and then generating a weight for each individual based on their corresponding stratum and treatment assignment, the stratification reduces bias in the observed covariates used to create the propensity score, and the weighting standardizes each treatment group to the target population [3]. This approach namely marginal mean weighting through stratification (MMWS), can handle a broad array of experimental conditions that researchers will likely encounter in evaluating health care interventions Once generated, the MMWS can then be used within the appropriate outcome model to estimate unbiased treatment effects [3].

II. LITERATURE REVIEW

A. *Structural Equation Modeling Partial Least Square (SEM-PLS)*

SEM-based variance or based components called as partial least square (PLS) is a method of analysis that is powerful and often referred to as soft modeling because it does not require assumptions such as data should not normally distributed multivariate, can be used with data of nominal, ordinal, interval and ratio, in addition sample should not be large [4]. SEM-PLS consists of three components are outer model is specifies the relationship between variables latent and indicators or manifest variables (measurement model), inner model is specifies the relationship between the latent variables (structural model), and the weight relation.

PLS is a powerful modeling methods due to not assume the data must be with particular scale of measurement, samples should not be large, not require extremely assumptions. Types of indicators on the PLS are two as follows:

- Reflective indicators tend to be influenced by the latent variables (indicators is a reflection of the latent variables).
- Formative indicators tend to affect the latent variables (indicators are descriptors of latent variables).

Algorithm SEM-PLS as explained by [5], can be illustrated by Figure 1.

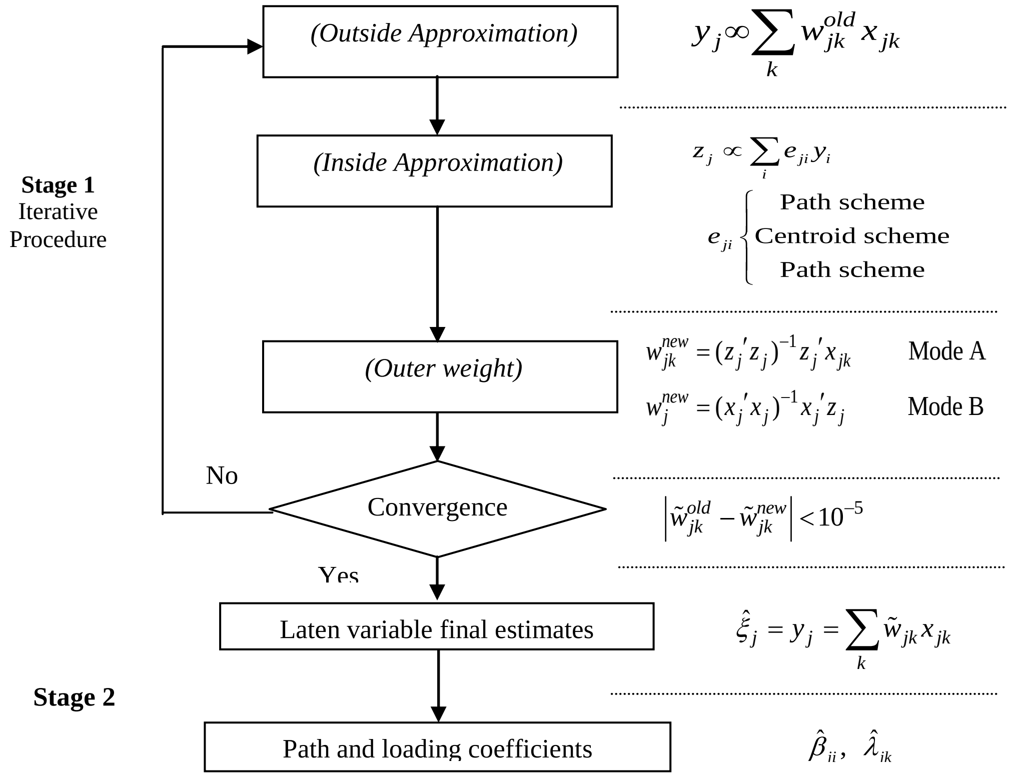

FIGURE 1. PLS ALGORITHM

Evaluation of PLS models is testing the validity and reliability. Validity testing performed to see the value of loading factor produced more than 0.5, if there are indicators has value loading factor below 0.5, then the are excluded from the analysis. Reliability testing show the composite value of each latent variable [6].

B. Propensity Score

The advantage of propensity score in comparison to multivariable adjustment is the separation of confounding factors adjustment and analysis of the treatment effect [7]. If the vector has many covariates were presented in many dimensions, then the propensity score can reduce all the dimensions into one dimension scores [2]. Rosenbaum and Rubin defined the propensity score for $i = 1, 2, \cdots, n$ as a conditional probability of being treated. Indicator of treatment group $(Z_i = 1)$ and control unit $(Z_i = 0)$ based on observed covariates vector (ξ_i). Propensity score can be written mathematically as follows:

$$e(\xi_i) = \mathrm{P}(Z_i = 1 | \xi_i) \tag{1}$$

The goal of propensity scoring is to balance the treated and untreated groups on the confounding factors that affect both the treatment assignment and the outcome, thus it is important to verify that treated and untreated patients with similar propensity score values are balanced on the factors included in the propensity score. Demonstrating that the propensity score achieves balance is more important than showing that the propensity score model has good discrimination [8].

C. Marginal Mean Weigthing through Stratification (MMWS)

Marginal mean weighting through stratification (MMW-S) was introduced as a flexible approach, combining propensity score weighting and propensity score stratification to remove imbalances of pre-intervention characteristics between two or more groups [3]. MMW-S produces more robust analysis than the methods of propensity score matching, propensity score stratification, and propensity score weighting [9].

$$MMWS = \frac{n_q \times \Pr(Z = z)}{n_{z=z,q}} \tag{2}$$

Where

n_q	= Number of individuals in each stratum
Pr(Z=z)	= Probability of the treatment group
$n_{z=z,q}$	= Number of individuals in each stratum is treated as treated / non-treated

D. HIV/AIDS

Human Immunodeficiency Virus (HIV) is a virus that reduces the body's immune system so that the people affected by this virus will be susceptible to various infections and then causes *Acquired Immune Deficiency Syndrome* (AIDS) [10]. The HIV is decreases gradually the immune system and leads to death as a direct result of one or more opportunistic infections. Opportunistic infection is an infection caused by immune deficiencies as a result of the HIV. Factors that influence the Opportunistic infection is predisposition and clinical manifestation. Predisposition is the internal factors that exist in individuals, families, communities that make easier individuals to behave. Clinical manifestations is presence indication of a disease that is perceived as complaints from patients and has been examined by a doctor or clinic. Predisposition include of age, level of education, work and marital status. And clinical manifestation include of CD4 and clinical stage.

III. METHODOLOGY

A. Source of Data

The data used in this research is secondary data on the medical records of HIV / AIDS patients in one hospital. The number is 91 patients HIV/AIDS. By using several variables as follows:

1. Exogenous Variables
   a Predisposition : age, level of education, work and marital status,
   b. Clinical manifestation : CD4 and clinical stage
2. Endogenous Variables: Opportunistic infection
3. Confounding variables: Adherence therapy ARV

B. Method of Analysis

Based on the research objectives, analysis methods used in this study is

1. Select confounding variables
2. Determine the propensity score approach to SEM
   a. Develop the conceptual model based on the theory
   b. Construct the path diagram
   c. Convert the path diagram into an equation system
   d. Estimate the parameters of model included
   e. Get the path coefficient value
   f. Determine the e propensity score value
3. Divide sample into Q strata based on propensity score and calculate the marginal mean weight

ISBN 978-602-74529-0-9

4. Examine the balancing of the covariates
5. Determine percentage bias reduction (PBR)

IV. ANALYSIS AND DISCUSION

A. Select confounding variable

Confounding variable according to the epidemiology is a situation where the size of the effect of distorted risk factors because of the correlation between exposure and other factors that influence the results [11]. The actual relationship between exposure factors and impact /disease factors are disappear or covered by other factors, so the influence of confounding factors can increase or decrease the actual relationship. Chi-square test was used to examine the relationship among variables, the following hypotheses [12]:

H_0: There is no significant relationship among variables

H_1: There is a significant relationship among variables

Significance level: $\alpha = 5\%$

Critical region: reject H_0 if $\chi^2 > \chi^2_{1-\alpha}; df = (i-1)(j-1)$ or p-value < α

TABLE 1. RELATIONSHIP BETWEEN ADHERENCE WITH PREDISPOSISI & CLINICAL MANIFESTASI

Variable	χ^2	***P-value***	**Decision**
ADH*Predisposition	5.315	0,021	reject H_0
ADH*Clinical manifestation	7.662	0,006	reject H_0

Based on the Table 1, can be seen that the adherence has a relationship with the predisposition and clinical manifestation. Therefore variable adherence is confounding variables. Diagram path after the formed variable interactions from compliance with adherence ARV the relationship among predisposition variables and adherence ARV the relationship among clinical manifestations of the opportunistic infection can be seen at figure 2.

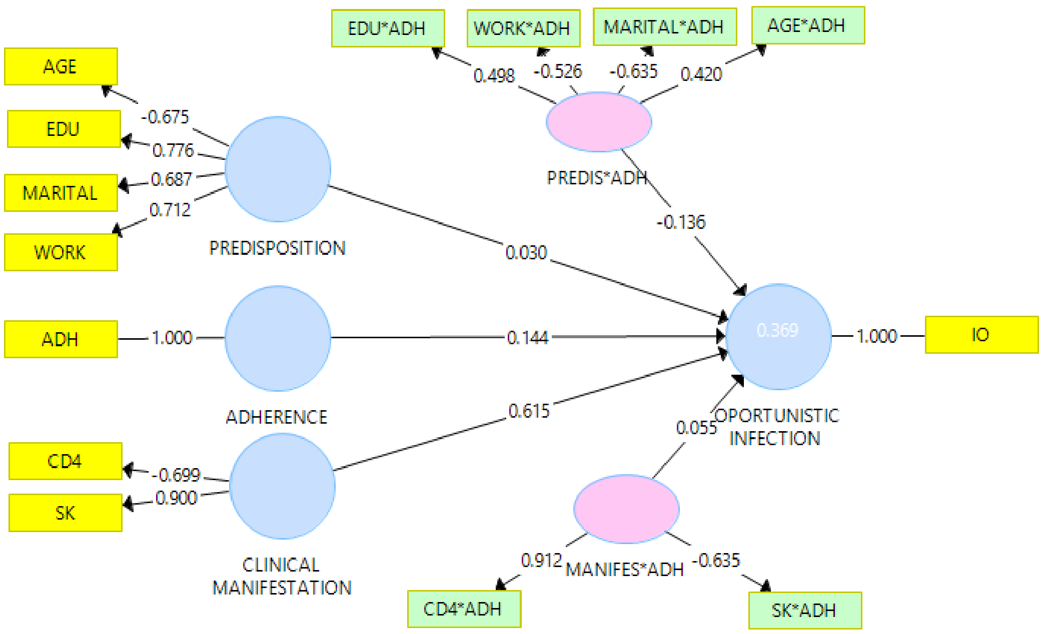

FIGURE 2. DIAGRAM PATH VARIABLE CONFOUNDING

Based on the figure 2 diagram path after putting confounding variables, the structural equation model is:

Opportunistic Infection = 0.030 predisposition + 0.144 clinical manifestation + 0.615 adherence - 0.136 (Predis*adh) + 0.050 (manifes*adh)

B. Calculating of MMWS

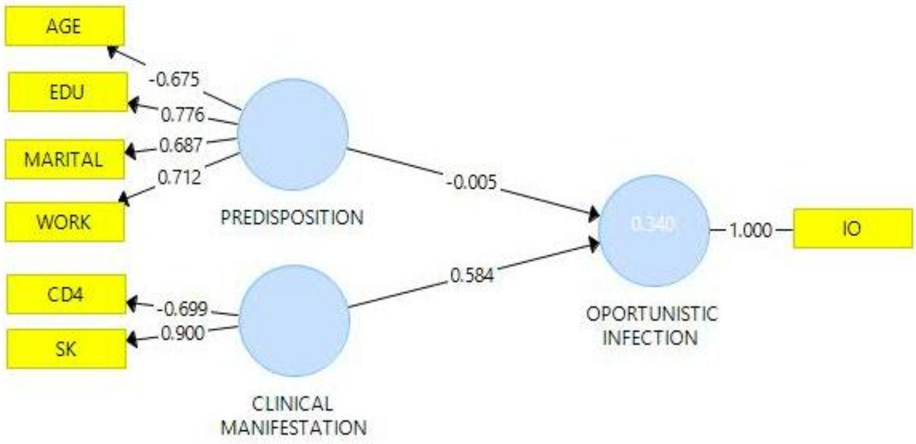

FIGURE 3 : LOADING FACTOR OF EACH LATEN VARIABLE

Based on the figure 2, can be seen that the loading factor of each indicator more than 0.5. Hence can be concluded that a valid indicator to measure the construct predisposition and clinical manifestation. Then calculate the propensity score using SEM-PLS. The propensity score for all respondents are used to divide respondents into five strata. Furthermore, calculating the marginal mean weight to tread groups and untreated groups uses the equation recommended as follows [9].

$$\frac{n_s \times \Pr(Z = z)}{n_{z=z,s}} \tag{3}$$

Where, n_s is the total number of individuals in stratum s, $\Pr(Z = z)$ is assignment probability to treatment groups z. $n_{z=z,s}$ is the total number of individuals in stratum s which is the actual treatment assignment for z.

TABEL 2. THE CALCULATION OF THE MMWS

Stratum	**Sample**	**Unweighted sample**		**MMWS**		**Weighted sample**	
		Treated	Untreated	z	z'	z	z'
1	19	10	9	0.626	1.42	6	13
2	18	6	12	0.989	1.01	6	12
3	18	4	14	1.484	0.86	6	12
4	18	8	10	0.742	1.21	6	12
5	18	2	16	2.967	0.75	6	12

After calculate MMWS can increase the homogeneity of propensity score between the treatment group and the control group in each stratum. The homogeneity or balance covariates in each stratum using the t-statistic for numerical variables. Insignificant T-values indicate adequate MMWS. The results of cheking balance covariate of each stratum are presented in Table 3.

TABLE 3: *T*-TEST FOR CHECKING BALANCE

Stratum	**Predisposition**			**Clinical Manifestation**		
	***T*-value**	$T_{(df,\alpha)}$	**Decision**	***T*-value**	$T_{(df,\alpha)}$	**Decision**
1	0.390	6.314	Not reject H_0	0.911	1.812	Not reject H_0

2	0.298	1.655	Not reject H_0	0.495	1.652	Not reject H_0
3	1.196	6.314	Not reject H_0	0.367	1.703	Not reject H_0
4	1.582	6.314	Not reject H_0	0.747	1.648	Not reject H_0
5	1.116	1.687	Not reject H_0	1.216	1.653	Not reject H_0

Based Table 3 shows that after MMWS there is no difference between the treatment group and control. Furthermore, compute a percentage bias reduction (PBR) on the covariate is another criterion to assess the effectiv of MMWS.

$$PBR = 100 \times \frac{\left(\overline{x}_t - \overline{x}_c\right)_{beforeMMWS} - \left(\overline{x}_t - \overline{x}_c\right)_{AfterMMWS}}{\left(\overline{x}_t - \overline{x}_c\right)_{AfterMMWS}} \quad (4)$$

Based on calculate of percentage bias reduction (PBR) obtained 93.5%. So that MMWS able to reduction bias 93.5%. It this sufficient of the bias reduction based on the examples in Cochran and Rubin PBR value of 80% or higher is satisfactory.

V. CONCLUSION

SEM-PLS can see that loading factor for each indicator on each latent variable is greater than 0.5, so that the indicators (age, level of education, work and marital status) were able to explain the predisposition variable and indicators (CD4, clinical stage) capable explain the clinical manifestation variable. Furthermore, score factor of each of the latent variables used to calculate a propensity score that will be used at this stage of Marginal mean through weighting stratification (MMWS) to reduce bias due to confounding variable. Marginal mean weighting through stratification (MMWS) method is a powerful because MMWS showed a reduction from the selection bias more than 93.5%.

Abstract**—**Nonparametric regression is used when regression curve is not known. Nonparametric regression curve is simply assumed to be smooth in the sense of space contained within a particular function. Data expected to find the shape of its estimation without being influenced by subjective factor of the researcher. Thus, the nonparametric regression approach has high flexibility. Nonparametric regression does not assume the shape of regression curve, regression curve is assumed to be contained within a particular function space. Infant deaths are deaths that occur in infants at an interval between time after birth until baby has not been exactly one year old. Magnitude which stated the possibility of babies die after birth until the age of one year per thousand live births is called Infant Mortality Rate (IMR). IMR data based on scatterplot with each predictor exhibits patterns that tend not follow a particular pattern (linear or a certain degree polynomial), so that the corresponding regression model approach is nonparametric spline regression model. Knot used is 1 knot, 2 knots and 3 knots and can be concluded that nonparametric regression model spline best produced is combination knot where significant variable are variable (X_1) The Percentage Of Aid Last Deliveries Performed By Non-Medical Assistance, (X_2) Marriage Percentages In Which Age of Women whom Married is Less Than 17 Years and (X_3) The Average Number Of Household Expenditure Per Capita Per Month.

Keywords: *nonparametrics, spline, knots, IMR*

I. INTRODUCTION

Regression modeling methods are divided into three, parametric regression, nonparametric regression and semiparametric regression. Semiparametric regression is used when one of the regression curve is not known, while others are known [1]. Nonparametric regression curve is only assumed to be smooth in the sense of space contained within a particular function. Data expected to find its shape of estimation, without being influenced by subjective factor of the researcher. Thus, the nonparametric regression approach has high flexibility [2]. Nonparametric regression does not assume the shape of regression curve, regression curve is assumed to be contained within a particular function space e.g. Sobolev Space (Eubank, 1988). In reality, not all of data model can be predicted with parametric regression approach in the absence of complete information about the regression curve shape. In such circumstances, it can be used nonparametric regression approach [3]. Nonparametric regression with spline approach is a method often used. In this study, we will estimate spline regression to model the function of Infant Mortality Rate (IMR) in Indonesia.

Infant deaths are deaths that occur in infants at an interval between the time after birth until the baby has not been exactly one year old. Magnitude which stated the possibility of babies die after birth until the age of one year per thousand live births is called Infant Mortality Rate (IMR). Based on the Indonesian Demographic and Health Survey, the IMR in Indonesia reached 32/1000 infant live births, this number is quite high compared to the standard of the Millennium Development Goals (MDGs), 23/1000 for IMR. Indonesian government is expected to reduce the value of IMR through programs initiated or to identify and resolve the factors that significantly affect the high value of IMR. East Java Province in the same year has IMR up to 32.43 deaths per 1,000 live births. In 2009 the IMR number is decreased to 31.41, while in 2010 the IMR became 29.99 deaths per 1,000 live births. This fact shows that East Java has not been able to reach the target of MDG's [4]. Data IMR based on scatter diagram with each predictor reveal patterns that tend not follow a particular pattern (linear or a certain degree polynomial), so that the corresponding regression model approach is nonparametric regression model. The characteristics of data IMR pattern is partially not have pattern so that the spline method is used to model the data pattern.

II. METHOD

A. Regression Analysis

Regression analysis is statistical analysis used to model the pattern of relationship between predictor variables and response variable. Parametric regression approach is used if the regression curve shapes are known. If relation of pattern data form linear pattern then used parametric linear regression approach. If relation of pattern data form a squares pattern then used quadratic regression approach, and others [2]. Relation of shape pattern can be identified based on past information or scatterplot of data [3].

B. Nonparametric Regression

Non-parametric regression is regression method approach in which the curve of regression function is unknown. The curve function assumed to be contained within a particular function space [2]. Nonparametric regression model is given by the following equation.

$$y_i = f(x_i) + \varepsilon_i, i = 1,2, \dots , n$$

with y_i is the response, variable, x_i is the predictor variables, $f(x_i)$ is the regression function, where the shape of the curve is unknown and ε_i are normally distributed random error, with zero mean and variance σ^2.

C. Nonparametric Spline Regression

Spline in nonparametric regression has high flexibility and the ability to estimate the behavior of data which tend to be different at different intervals [2]. This ability to estimate the behavior of data is indicated by the truncated function (pieces) which are attached to the estimator and pieces of so-called point knots. Knot point is the point of fusion joint that show changes in behavior patterns functions of different interval. Spline is one kind of piecewise polynomial, polynomial which has segmented nature. The segmented nature provides more flexibility than ordinary polynomials, thus allowing it to adapt more effectively to the local characteristics of a function or data. Spline function of degree p is any function that can generally presented in the following forms:

$$f(x_i) = \sum_{j=0}^{p} \beta_j x_i^j + \sum_{j=1}^{k} \beta_{j+p} (x_i - k_j)_+^p$$

with β_j are real constants, and

$$(x_i - k_j)_+^p = \begin{matrix} (x_i - k_j)^p & ; x \geq k_j \\ 0 & ; x < k_j \end{matrix}$$

If p = 1, 2, and 3 respectively spline linear, quadratic and cubic spline spline and k_j is point knots.

Assuming an error ε_i independent normal distribution with average zero and variance σ^2, then y_i in regression models also normally distributed with an average $f(x_i)$ and variance σ^2. Estimates for the parameter β by using the least squares method, namely by minimizing the sum of squared errors is as follows,

$$\sum_{i=1}^{n} \varepsilon_i^2 = \sum_{i=1}^{n} \left(y_j - f(x_i)\right)^2$$

β estimator can be obtained from minimizing

$$Q(\beta) = (y - X\beta)^T (y - X\beta)$$

To obtain the best spline regression estimator, it is necessary to select knots optimal point. Method used is Generalized Cross Validation (GCV). GCV functions as follows:

$$GCV(K_1, K_2, \dots , K_r) = \frac{MSE(K_1, K_2, \dots , K_r)}{\left(n^{-1} tr\left[I - A\left((K_1, K_2, \dots , K_r)\right)\right]\right)^2}$$

Value $(K_1, K_2, \dots , K_r)$ is the point of knots, while the matrix $A(K_1, K_2, \dots , K_r)$ obtained from the equation $\hat{y} = A(K_1, K_2, \dots , K_r)\tilde{y}$ and $MSE(K_1, K_2, \dots , K_r) = n^{-1} \sum_{i=1}^{n} (y_i - \hat{y}_i)^2$

III. PROCEDURES

This study uses secondary data from the Central Bureau of Statistics (BPS) in 2011. Observation unit in this study was 38 district/city in East Java in 2011. The variables used are Infant Mortality Rate (IMR), the percentage of aid last deliveries performed by non-medical assistance, marriage percentages in which age of women whom married is less than 17 years, the average number of household expenditure per capita per month, the percentage of infants aged 0-11 months were given breast milk, and the number of health facilities (hospitals and health centers). Step analysis are carried out as follows.

1. Creating a scatter plot between response variable with each predictor variable.
2. Modeling data using spline estimation with various knots (one knot, two knots and three knots).
3. Choosing the optimal knots point with GCV method
4. Establish the best models from the smallest GCV value.
5. Calculate the MSE and R^2 of data.

IV. RESULT AND DISCUSSION

After the text edit has been completed, the paper is ready for the template. Duplicate the template file by using the Save As command

A. Characteristics of Infant Mortality and Factors Affecting

Data infant mortality rate and factors that influence described using mean, standard deviation, minimum and maximum values. Here are the characteristics of infant mortality data and factors that influence are presented in Table 1.

TABEL 1. CHARACTERISTICS OF INFANT MORTALITY AND FACTORS AFFECTING

Variable	**Mean**	**Standard Deviation**	**Minimal**	**Maximal**
Y	34,18	12,68	20,02	64,19
X_1	8,31	11,19	0,00	44,99
X_2	27,00	13,00	10,07	59,09
X_3	239322	105660	122240	558590
X_4	93,952	4,640	83,920	100,000
X_5	90,11	39,94	13,00	189,00

B. Scatterplot Data Infant Mortality and Factors Affecting

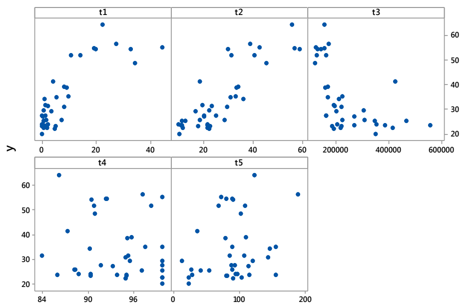

FIGURE 1. SCATTERPLOT DATA

Based on Figure 1, it shows that the relationship between the variables in infant mortality with each factor does not follow specific pattern because plot data is scattered randomly. Thus, the independent variable is nonparametric component.

C. Nonparametric Spline Truncated Regression Model

Nonparametric regression model, truncated spline, with a single point of knots in general are as follows.

$$y_i = \gamma_0 + \gamma_1 t_{i1} + \gamma_2 (t_{i1} - k_1)_+ + \gamma_3 t_{i2} + \gamma_4 (t_{i2} - k_1)_+ + \gamma_5 t_{i3} + \gamma_6 (t_{i3} - k_1)_+ + \gamma_7 t_{i4}$$
$$+ \gamma_8 (t_{i4} - k_1)_+ + \gamma_9 t_{i5} + \gamma_{10} (t_{i5} - k_1)_+ + \varepsilon_i$$

Here are iteration results of the best knot point value based on GCV minimum.

TABLE 2. SINGLE POINT OF KNOT

Knot X_1	**Knot X_2**	**Knot X_3**	**Knot X_4**	**Knot X_5**	**GCV**
0.92	11.07	131145.10	84.25	16.59	36.39
1.84	12.07	140050.20	84.58	20.18	36.66
2.75	13.07	148955.31	84.90	23.78	37.06
10.10	21.07	220196.12	87.53	52.51	37.50
11.02	22.07	229101.22	87.86	56.10	37.70

In Table 2, GCV smallest value obtained was 36.39. The value of knot point for variable X_1 is 0.92, variabel X_2 is 11.07, variable X_3 is 131145.10, variable X_4 is 84.25 and variable X_5 is 16.59.

Truncated spline nonparametric regression model with two point knots in general are as follows.

$$y_i = \gamma_0 + \gamma_1 t_{i1} + \gamma_2 (t_{i1} - k_1)_+ + \gamma_3 (t_{i1} - k_2)_+ + \gamma_4 t_{i2} + \gamma_5 (t_{i2} - k_1)_+ + \gamma_6 (t_{i2} - k_2)_+ + \gamma_7 t_{i3}$$
$$+ \gamma_8 (t_{i3} - k_1)_+ + \gamma_9 (t_{i3} - k_2)_+ + \gamma_{10} t_{i4} + \gamma_{11} (t_{i4} - k_1)_+ + \gamma_{12} (t_{i4} - k_2)_+ + \gamma_{13} t_{i5}$$
$$+ \gamma_{14} (t_{i5} - k_1)_+ + \gamma_{15} (t_{i5} - k_2)_+ + \varepsilon_i$$

Here are iterations results of two points based on the best knots GCV minimum.

TABLE 3. TWO POINT OF KNOT

X_1		X_2		X_3		X_4		X_5		**GCV**
K_1	K_2	K_1	K_2	K_1	K_2	K_1	K_2	K_1	K_2	
11,9	42,2	23,1	56,1	238006,3	531874,7	88,2	99,0	59,7	178,2	31,9
11,0	42,2	22,1	56,1	229101,2	531874,7	87,9	99,0	56,1	178,2	32,0
11,9	43,2	23,1	57,1	238006,3	540779,8	88,2	99,3	59,7	181,8	32,0
11,0	43,2	22,1	57,1	229101,2	540779,8	87,9	99,3	56,1	181,8	32,1
11,9	44,1	23,1	58,1	238006,3	549684,9	88,2	99,7	59,7	185,4	32,1

Based on Table 3, GCV smallest value obtained was 31.9. The value of knot point for variable X_1 are $k1$ amounted to 11,9 and k2 amounted to 42,2. Knots point value for variable X_2 are $k1$ amounted to 23.1 and k2 amounted to 56.1 $k2$. For variable X_3 are $k1$ amounted to 238006.3 and $k2$ amounted to 531874.7. For variable X_4 are $k1$ amounted to 88,2 and $k2$ amounted to 99.0, while for the variable X_5 are $k1$ amounted to 59.7 and $k2$ amounted to 178.2.

Nonparametric regression model with a three-point spline truncated knots in general are as follows..

$$y_i = \gamma_0 + \gamma_1 t_{i1} + \gamma_2 (t_{i1} - k_1)_+ + \gamma_3 (t_{i1} - k_2)_+ + \gamma_4 (t_{i1} - k_3)_+ + \gamma_5 t_{i2} + \gamma_6 (t_{i2} - k_1)_+$$
$$+ \gamma_7 (t_{i2} - k_2)_+ + \gamma_8 (t_{i2} - k_3)_+ + \gamma_9 t_{i3} + \gamma_{10} (t_{i3} - k_1)_+ + \gamma_{11} (t_{i3} - k_2)_+$$
$$+ \gamma_{12} (t_{i3} - k_3)_+ + \gamma_{13} t_{i4} + \gamma_{14} (t_{i4} - k_1)_+ + \gamma_{15} (t_{i4} - k_2)_+ + \gamma_{16} (t_{i4} - k_3)_+ + \gamma_{17} t_{i5}$$
$$+ \gamma_{18} (t_{i5} - k_1)_+ + \gamma_{19} (t_{i5} - k_2)_+ + \gamma_{20} (t_{i5} - k_3)_+ + \varepsilon_i$$

Here are the result of three-point iteration based on the best knots GCV value minimum.

TABLE 4. THREE POINT OF KNOT

		X_1	X_2	X_3	X_4	X_5	GCV
	K_1	0.92	11.07	131145.10	84.25	16.59	
1	K_2	11.94	23.08	238006.33	88.19	59.69	28.36858
	K_3	41.32	55.09	522969.59	98.69	174.63

2	K_2	11.94	23.08	238006.33	88.19	59.69	28.38476
	K_3	42.24	56.09	531874.69	99.02	178.22	
	K_1	0.92	11.07	131145.10	84.25	16.59	
3	K_2	11.94	23.08	238006.33	88.19	59.69	28.39802
	K_3	43.15	57.09	540779.80	99.34	181.82	
	K_1	0.92	11.07	131145.10	84.25	16.59	
4	K_2	11.94	23.08	238006.33	88.19	59.69	
	K_3	44.07	58.09	549684.90	99.67	185.41	28.40616
	K_1	0.92	11.07	131145.10	84.25	16.59	
5	K_2	22.04	34.08	335962.45	91.80	99.20	28.60887
	K_3	24.79	37.08	362677.76	92.78	109.98	

Based on Table 4, GCV smallest value obtained is 24.67.

D. Optimal Knot Point Selection

After getting knots value for each predictor variable, the next step is to compare GCV value of each model to choose which one is the best knots. Here are the smallest GCV value of each point knots results.

TABLE 5. SMALLES GCV VALUE FROM EACH MODELLING

Knot	**GCV**
1 Knot	36.4
2 Knots	31.9
3 Knots	28.4
Knot Combinations	27.3

Bold –Knot value which has smallest GCV

The smallest GCV value is modeling with knot combinations that is equal to 27,3.

E. Modelling Infant Mortality by Optimal Knot Point

The combination of knots optimum point is

$$\begin{aligned}\hat{y} = &-0.00003 + 0.1569x_{i1} + 0.1524(x_{i1} - 0.9182)_+ + 0.2183x_{i2} + 0.2178(x_{i2} - 11.07)_+ \\ &+0.00037x_{i3} - 0.000054(x_{i3} - 13145.1)_+ + 0.000024(x_{i3} - 238006.3)_+ \\ &-0.000062(x_{i3} - 522969.6)_+ - 0.14976x_{i4} - 0.1463(x_{i4} - 84.25)_+ \\ &-0.118x_{i5} + 0.2211(x_{i5} - 59.69)_+ + 0.0283(x_{i5} - 178.22)_+\end{aligned}$$

R^2 value of this model is 89.38 percent. This means that 10.62 percent of IMR are able to be explained by variable percentage of aid last deliveries performed by non-medical assistance, marriage percentages in which age of women whom married is less than 17 years, the average number of household expenditure per capita per month, the percentage of infants aged 0-11 months were given breast milk, and the number of health facilities in Spline Regression Model Truncated with combination knot of optimum knots.

F. Parameter Regression Examination

There are two test parameter estimation to be performed, simultaneously testing and individual testing. Here are the results of simultaneously testing by using F-statistic test.

TABLE 6. ANALYSIS OF VARIANCE

Variance Source	db	*Sum Square*	*Mean Square*	F	P-*value*
Regresi	13	5308.908	408.3775	16.20971	8.23152e-09
Error	24	604.6414	25.19339		
Total	37	5913.549			

F-test value is 16.21 and the F degree of freedom table value for v_1 amounted to 13 and v_2 amounted to 24. Thus, the value of F-test > F_{tabel} so it can be concluded that we rejected H_0 which mean there are at least one predictor variable which has significant impact on the model. Next step is doing individual testing to determine what variables that has significant impact. The results of individual tests are presented in Table 7.

TABLE 7. INDIVIDUAL TESTING PARAMETER RESULTS

Variable	Parameter	Estimator	*t*	P-*value*
Konstan	γ_0	-3.532E-05	-0.285	0.77833

X_4	γ_9	-1.497E-01	-1.563	0.131213
	γ_{10}	-1.463E-01	-1.602	0.122276
X_5	γ_{11}	-1.118E-01	-1.122	0.273009
	γ_{12}	2.211E-01	1.778	0.088093
	γ_{13}	2.829E-02	1.418	0.168963

Individual parameter test results of 14 parameters which are contained in nonparametric spline regression model, 6 parameters are not significant because p-value is greater than α. The significant parameters are $\gamma_2, \gamma_3, \gamma_4, \gamma_5, \gamma_6, \gamma_7$ and γ_8.

G. Testing Residual Assumption

Residual assumptions that must be fulfilled to find the best model are assumption of identical residual, independent and normally distributed. Testing assumptions using identical residual test presented Glejser role is in the following Table

TABLE 7. GLEJSER TESTING RESULTS

Sumber Variasi	db	*Sum Square*	*Mean Square*	F	P-*value*
Regresi	13	47.904	3.685	0.514	0.894
Error	24	172.184	7.174		
Total	37	220.088			

P-value of Glejser testing residual is 0.894, the value is greater than the value of α of 0.05, so can be concluded that H_0 failed to reject it means that heteroskedastisity is not occur in the model so that identical residual assumption are met. Examination of independent residual assumption use ACF plot is presented in Figure 2 below.

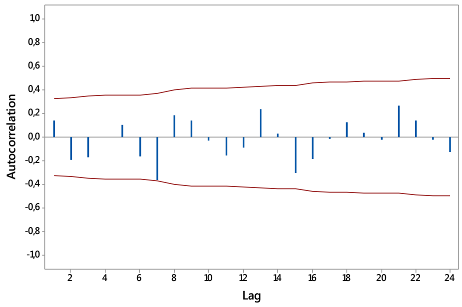

FIGURE 2. RESIDUAL ACF PLOT

Based on ACF plot for residual, there is no significant autocorrelation (ACF) values or out of the upper limit and lower limit. It can be concluded that the assumption of residuals independent are met and no autocorrelation between residuals. Here is residual normal distribution testing using Kolmogorov Smirnov test statistics that are presented in Figure 3.

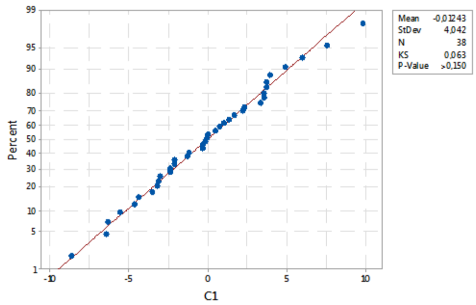

FIGURE 3. RESIDUAL NORMALITY PLOT

Based on normality plot model residual, obtained p-value is greater than 0.150 where the value is greater than the value of α which is equal to 0.05. Testing for normality using Kolmogorov Smirnov statistics with p-value > α can be concluded that H_0 failed to reject, which means residual has normal distribution. So, assumption of normal distribution are met. The test results for assumption of identical residual, independent, and normal distribution are met, then the model used is appropriate and can be done interpretation of the best model.

CONCLUSIONS

Based on modeling results of infant mortality rate in Indonesia using nonparametric regression splines can be concluded that truncated nonparametric spline regression model is the best produced knots with determination coefficient of 89.38 percent where significant variablea are variable (X_1) The Percentage Of Aid Last Deliveries Performed By Non-Medical Assistance, (X_2) Marriage Percentages In Which Age Of Women Whom Married Is Less Than 17 Years and (X_3) The Average Number Of Household Expenditure Per Capita Per Month.

Construction of Fuzzy System of Zero-Order Takagi-Sugeno-Kang Using Singular Value Decomposition Method and Its Application for Diagnosing Cervical Cancer

Triyanti[1], Agus Maman Abadi[2]
Department of Mathematic, Yogyakarta State University
[1]triyantincut@gmail.com

Abstract—Cervical cancer is a deadly disease for women. But over the last 30 years, the cervical cancer death rate has gone down by more than 50%. The main reason for this change was the increased use of the Pap test. Therefore, it is very important to perform early detection and diagnosis to determine the possibility of cervical cancer. Fuzzy System can be used for diagnosis of cervical cancer. In this paper, the diagnosis of cervical cancer stage is based on colcoscopic images that have been extracted to 21 properties of the image. Those properties are selected that yield four image extractions those are difference entropy, mean, correlation and sumaverage. These four extractions are used as input variables to the fuzzy system built using Gauss curve representation. The output variables of this system are normal, stage 1, stage 2, stage 3 and stage 4. Fuzzy rules of zero-order Takagi-Sugeno-Kang fuzzy system are developed by singular value decomposition method. This method is used to determine the parameters of consequent of rules. In this paper, we use 80 training data and 10 testing data. The 80 training data yield 80 fuzzy rules. Then, the method of weight average is applied to defuzzification process. The results are that the accuracy, sensitivity, and specification of the fuzzy system are 83,8%; 100%; and 84,6%, respectively. While for test data, the accuracy, sensitivity, and specification of the fuzzy system are 70%; 100%; and 50%, respectively. Fuzzy system that has been formed is implemented with a Graphical User Interface (GUI).

Keywords: *cervical cancer, zero order Takagi-Sugeno-Kang, fuzzy system, singular value decomposition*

I. INTRODUCTION

Cervix is a part of the female reproductive system. Cervical cancer affects the cervix inside the pelvis. The disease is caused by HPV (Human Papilloma Virus). Cervical cancer is a deadly disease for women in both developed and developing countries. According to [1], the mortality rate of cervical cancer has dropped by more than 50% for the last 30 years. The main reason for this change is an increase in the use of Pap smear tests. Which serve as early detection. Therefore, early detection of cervical cancer need to be done in order to be given the proper treatment or medication. That reason makes many research on the early detection of cervical cancer has been conducted.

Reference [2] classified cervical cancer with a combination of fuzzy model and stepwise regression. Inputs used are extracted colposcopy images from various stages of cervical cancer which generates 21 image properties. Furthermore, twenty-one properties were selected using stepwise regression to obtain a more dominant trait for input on fuzzy model. The process of fuzzy inference model using Mamdani method. Later model is used to predict whether a person is diagnosed normal, stage 1, stage 2, stage 3, or stage 4 of cervical cancer. The accuracy of the model reached 95% on 90% of the training data and testing data.

Researchers are continually improve the diagnosis of cervical cancer by a variety of methods. Fuzzy logic is one of the methods used to perform the diagnosis of cervical cancer. One of the method of fuzzy inference in fuzzy model is a zero-order Takagi-Sugeno-Kang (TSK) method. Zero order TSK method has an easier calculations. Based on [2], the authors use diagnosis of cervical cancer with the zero-order TSK fuzzy inference process. Then, singular value decomposition is used to determine of the consequent of the rule of the zero order TSK.

II. RESEARCH METHOD

The data used in this study are 90 colposcopy extraction results of secondary data obtained from research by [2]. Ninety colposcopy data used in this study are divided into two separate data, those are 80 training data and 10 testing data. Step-by-step analysis of the data is presented in Figure 1.

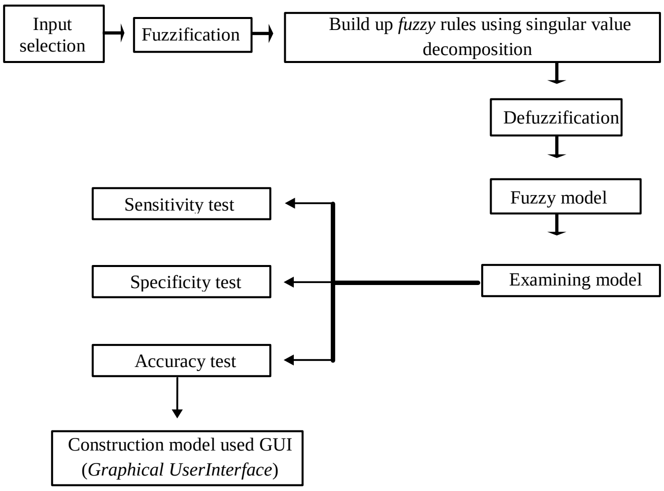

FIGURE 1. STEP STUDY CHART

After the built fuzzy system has good accuracy, the next step is to construct of interface for the fuzzy model use Graphical User Interface (GUI) matlab so that the display system will be more attractive. The basic design GUI (Graphical User Interface) for cervical cancer shown by Figure 2.

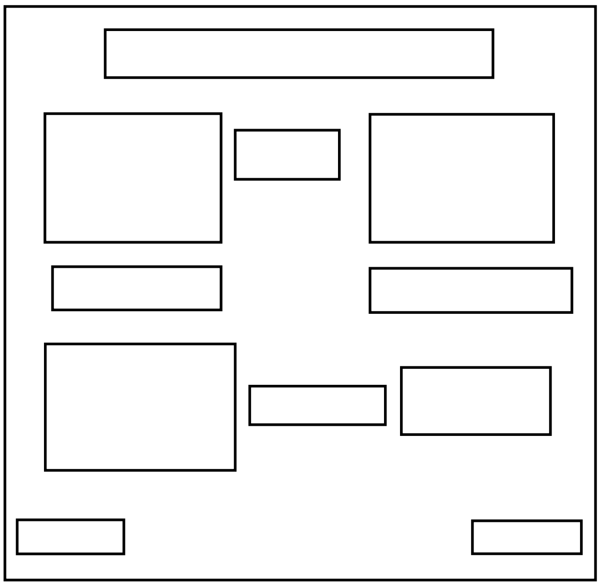

FIGURE 2. PRELIMINARY DRAFT GUI DISPLAY

III. DISCUSSION

Cervical colposcopy image extraction process produces 21 nature pictures. Furthermore, the nature of the twenty-first selected using stepwise regression method, resulting in a 4 properties significantly to the diagnosis of cervical cancer. Four properties were obtained difference entropy, correlation, mean, sum average. Extraction image process and selecting properties significantly to the diagnosis has been made by [2].

A. Fuzzification

Each input is defined in the fuzzy set based on the universal set. The set can be determined with a universal approach of the minimum value and the approach of the maximum value of the data of the extracted image. The set of four input is universal for difference entropy (D) = [0,19 0,62], correlation (C) = [0,86 0,99], mean (M) = [52 185] and sum average (S) = [4,3 12,6]. Furthermore, each input fuzzy set represented in the membership function Gauss curve. Gauss curve membership functions in Matlab as follows:

$$f(x,\theta,c) = e^{\frac{-(x-c)^2}{2\theta^2}} \tag{1}$$

Each input is divided into 9 fuzzy sets in the same range, for the entropy difference is D1, D2, D3, D4, D5, D6, D7, D8, D9. Gauss curve representation for entropy difference is shown in Figure 3.

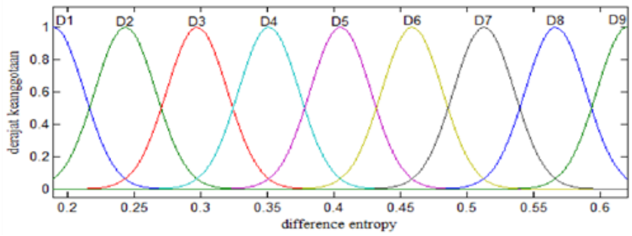

FIGURE 3. MEMBERSHIP FUNCTION OF DIFFERENCE ENTROPY

Furthermore, the output is defined in the nearest rounding constant number which are divided into five numbers, 0, 1, 2, 3, and 4. Numbers 0 is a normal phase, 1 is a stage 1, 2 is a stage 2, 3 is a stage 3 and 4 is the phase of a stadium stage 4 cervical cancer.

B. Constructing Fuzzy Rules

Each value extraction results on the training data used as input sought the largest membership value in fuzzy set to build the fuzzy rules. The following is the result of the first training data and grouping in the fuzzy set.

TABLE 1. RESULTS FIRST DATA EXTRACTION AND CLASSIFICATION OF FUZZY INPUT IN SET

Data	Ekstraction results	Fuzzy Set
Difference Entropy	0.36838	D_4
Correlation	0.94068	C_6
Mean	171.0023	M_8
Sum Average	11.6581	S_8
Diagnosis		Stage 1

Thus the rules established for training data number 1 are as follows:
Rule (1) If difference entropy is D_4 and correlation is C_6 and mean is M_8 and sum average is S_8 Then stage 1.
All of training data calculation, obtained 74 rules. Inference system used the zero order TSK method. In general form of zero order TSK [3] are as follows:

$$\text{If } (x_1 is\ A_1)\ o\ (x_2 is\ A_2)\ o \ldots o\ (x_i is\ A_i) \text{ Then } y = b_i \tag{2}$$

where b is a constant. The fuzzy rules for fuzzy rules zero order system of TSK become
Rule (1) If difference entropy is D_4 and correlation is C_6 and mean is M_8 and sum average is S_8 Then $y_1 = b_1$.

C. Defuzzification

The process of defuzzification in this resarch using the method of weight average with formula [4]:

$$y = \frac{\sum_{i=1}^{L} y_i(\mu_{i1}(x_1)\mu_{i2}(x_2)...\mu_{in}(x_n))}{\sum_{i=1}^{L} \mu_{i1}(x_1)\mu_{i2}(x_2)...\mu_{in}(x_n)} \tag{3}$$

The (3) equation can be stated as

$$y = \sum_{i=1}^{L} w_i y_i \tag{4}$$

where $w_i = \frac{\mu_{i1}(x_1)\mu_{i2}(x_2)...\mu_{in}(x_n)}{\sum_{i=1}^{L} \mu_{i1}(x_1)\mu_{i2}(x_2)...\mu_{in}(x_n)}$. Next, based on [5] set up a model which minimizes the objective function J with

$$J = \sum_{k=1}^{N} \big(d(i) - y(i)\big)^2 = (d - Xb)^T(d - Xb) \tag{5}$$

where $d(i)$ is the real output for all data pairs i, $y(i)$ is the zero order TSK model output for all data pairs i. Then $d = [d(1)d(2) \dots d(N)]^T$, X is the matrix with size $N \times L$, where N is the number of data and L is the amount of formed fuzzy rules and $b = [b_{10}\ b_{11}\ \dots\ b_{1n}\ \dots\ b_{L0}\ b_{L1}\ \dots\ b_{Ln}]^T$ is the matrix with size $L \times 1$. The equation (5) can be achieved a minimum if $d - Xb = 0$ or $d = Xb$ with

$$X = \begin{bmatrix} w_1(1) & w_2(1) & \cdots & w_{74}(1) \\ w_1(2) & w_2(2) & \cdots & w_{74}(2) \\ \vdots & \vdots & \vdots & \vdots \\ w_1(80) & w_2(80) & \cdots & w_{74}(80) \end{bmatrix} = \begin{bmatrix} 0.9256 & 0.0256 & \dots & 0.0000 \\ 0.0006 & 0.9994 & \dots & 0.0000 \\ \vdots & \vdots & \vdots & \vdots \\ 0.0000 & 0.0000 & \dots & 0.0000 \end{bmatrix}$$

Then, the solution of $d = Xb$ can be solved using sigular value decomposition. The singular value decomposition of X [6] is $X = USV^T$, where U and V are unitary matrix and S is matrix $m \times n$ which all entries on the diagonal is a singular entri value where zero beyond the diagonal. The parameter *b* can be determined with formula [7] :

$$\hat{b} = \sum_{i=1}^{r} \sigma_i^{-1} < d, u_i > v_i = \sum_{i=i}^{r} \frac{u_i^T d}{\sigma_i} v_i \tag{6}$$

where r is count of non zero singular value, $U = [u_1, \dots, u_N]$, dan $V = [v_1, \dots, v_{(n+1)L}]$. Based on the equation (6) will be obtained constants $b = [1\ 1\ \dots\ 0]^T$.

Then k constant substitutable in 74 rules and gained rules for the training data number -1:

Rule (1) If *difference entropy* is D_4 and *correlation* is C_6 and *mean* is M_8 and *sum average* is S_8 Then $y_1 = 1$.

Further for the process of *defuzzification* can be calculated using equation (3). Once obtain the value of defuzzification, can be done a testing system to get accuracy rate, sensitivity rate, and specification rate. The formula for the accuracy level [8]:

$$accuracy = \frac{the\ number\ of\ the\ correct\ data}{the\ amount\ of\ entirely\ data} \times 100\% \tag{7}$$

$$sensitivity = \frac{TP}{TP+FN} \times 100\% \tag{8}$$

$$specification\ \frac{TN}{TN+FP} \times 100\% \tag{9}$$

Result defuzzification of training data is shown in Table 2.

TABLE 2. RESULT DEFUZZIFICATION OF TRAINING DATA

No.	y	Actual Stage	Predicted Stage	Performance measure
1	1	Stage 1	Stage 1	TP
2	1	Stage 1	Stage 1	TP
3	1	Stage 1	Stage 1	TP
4	1	Stage 1	Stage 1	TP
⋮				
80	0	Normal	Normal	TN

D. Result

Based on the *defuzzification* process done toward the train data achieved the classification result of cervical cancer. Thus can be calculated to examin the accuracy level from the training data which are the accuracy, sensitivity, and specification are 83,8%; 100%; and 84,6%, respectively. However in testing data, the level of accuracy is 70%, sensitivity is 100%, and the specificity is 50%.

Model diagnosis of cervical cancer are built with fuzzy model that has been tested, then construct a fuzzy model with a GUI to make it more attractive and easier for users. The final design model of diagnosis of cervical cancer stage with the GUI shown in Figure 4.

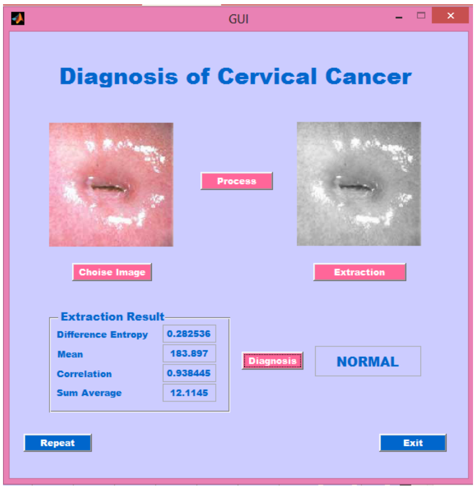

FIGURE 4. GUI DISPLAY RESULT OF NORMAL CERVIK DATA

IV. CONCLUSION

Ninety of data extraction of colposcopy images are divided into 80 data and 10 data testing training. Input on fuzzy model built using Gauss curve representation. Each input is divided into 9 fuzzy sets. Inference system used zero-order TSK method. Determination of the constants in the consequent of the rule that is built using singular value decomposition. Defuzzification process on the model using the method of weight average. If-Then fuzzy rules formed from the training data and obtained 74 rules. Output models which are a normal cervical cancer diagnosis, stage 1, stage 2, stage 3 and stage 4.

After a fuzzy model is established, the model accuracy for 80 training data accuracy, sensitivity and specificity was 83.8%; 100%; and 84.6%. Then, for the 10 data defuzzification results of testing showed levels of accuracy, sensitivity, and the specificity of 70%, 100% and 50%. Thus, the fuzzy model which has been built well enough represent a diagnosis.

Construction of Fuzzy Rules of Zero Order Takagi-Sugeno-Kang Fuzzy System Using Generalized Matrix Inverse Method and Its Application for Diagnosing Breast Cancer

Weni Safitri[1], Agus Maman Abadi[2]
Department of Mathematic, Yogyakarta State University
wenisafitri.weni@gmail.com[1]

Abstract**—**Breast cancer is one of the most cancerous in Indonesia that the mortality rate is quite high. To date, the primary causes of breast cancer are still unknown. Therefore, early detection and diagnosis are needed to determine the possibility of breast cancer. One way to detect this cancer is with mammogram image. The aims of this study is to explain steps in applicating fuzzy system for breast cancer diagnosis using mammogram image and implement the result with GUI (Graphical User Interface). Another aims of this study is to compare the result with previous research. This study using 120 mammogram images that divided into 96 training data and 24 testing data. The fuzzy system used is zero order Takagi-Sugeno-Kang with 10 input variables and 3 output variables. To optimize the result, generalized matrix inverse method is used in building fuzzy rules and weight average method for defuzzification process. The accuracy, sensitivity, and specification of the zero order Takagi-Sugeno-Kang fuzzy system are 100% for training data. For testing data, the accuracy, sensitivity, and specification of the system are 50%, 77.77%, 66.67%, respectively. Whereas the accuracy of the Mamdani fuzzy system reached 96.875% and 100% for sensitivity, and specification in training data. In the testing data, the Mamdani fuzzy system reached 91.67%, 93.75%, and 87.5% in accuracy, sensitivity, and specification respectively. Based on these result, it can be concluded that the zero order Takagi-Sugeno-Kang fuzzy system is better than the Mamdani fuzzy system in training data, but need much improvement for testing data.

Keywords:*breast cancer diagnosis,mammogram image, fuzzy system, GUI*

I. INTRODUCTION

Breast cancer is a disease which the cells (tissue) of breast are grown and spread uncontrollably. The disease occurs almost entirely in women, but men can get it, too [1]. The breast cancer is one of malignant tumors which have been common to be found, WHO (World Health Organization) numerated breast cancer is the number one killer that threaten women's health [2]. According to 2012 data of GLOBOCAN (IARC) found that breast cancer is cancer disease with percentage of recent cases (controlled by age) the highest is 43.3% and mortality percentage (controlled by age) caused by breast cancer is 12.9% [3].

To date, the primary causes of breast cancer are still unknown. Even the symptom and the growth itself are hard to detect. Symptoms usually only discovered after the stage of the cancer develops further, because usually it does not cause any complaints in the early stages. Patients feel well, they do not feel any pains, and does not interfere to the activity. This condition causes many sufferers seek treatment in a state of advanced stage of cancer. This situation can complicate the healing process even increase the risk of death for patients. It will be much easier to do treatment when breast cancer can be found earlier [1].

Perceiving the importance of early detection and diagnosis of breast cancer makes many researchers conduct research in the diagnosis of breast cancer. Gerald Schaefer *et al* conduct research that aims to diagnose breast cancer using fuzzy classification method based on data calorimetry [4]. Hossein Ghayoumi Zadeh *et al* conduct research to detect breast cancer by combining breast thermography with Complementary Learning Fuzzy Neural Network (CLFNN) methods and built with image processing [5].

Shleeg and Ellabib diagnosed breast cancer using the method of Mamdani Fuzzy Inference System. They used the nine rules compared to Sugeno Fuzzy Inference System method [6]. In the same year Ali and Ayturk conducted research that aims to diagnose breast cancer using neuro-fuzzy classification method called NEFCLASS [7]. Research conducted by [8] to diagnose breast cancer with point operation using image mammogram data and implemented with a Graphical User Interface (GUI). In this study, the fuzzy inference process carried out by the mamdani method.

Based on the description above, it can be seen that the current research on the diagnosis of breast cancer has been conducted by researchers with a variety of methods. One widely used method associated with the diagnosis of breast cancer is fuzzy logic. Fuzzy logic is an appropriate way to map an input space into an output space. Fuzzy Logic will deliver value to an uncertainty as well, sufficient, and close [9].

Basically, there are a fuzzy system that can be used as a method in diagnosing breast cancer. For example, a diagnosis of breast cancer using mamdani fuzzy system that previously had been performed by [8]. In addition to the fuzzy system mamdani, other methods that may be used is zero-order Sugeno fuzzy system. Therefore, to compare between the two fuzzy system is then carried out further research into the diagnosis of breast cancer with the zero-order Sugeno fuzzy system.

In the establishment of zero-order Sugeno fuzzy systems there is the possibility that the rules were formed less than the consequent parameter estimated. Based on the rules and the consequent parameters can form a non-invertible matrix. Matrix non-invertible is hard to solve using the usual inverse so other methods are needed to solve them. The method that can be used is the inverse matrix of generalized or often referred to as pseudo-inverse. This method is general and can be used to find the inverse of any type of matrix including a non-invertible matrix. Based on the description above, underlie the author to conduct research on zero-order Sugeno fuzzy system in the diagnosis of breast cancer with generalized matrix inverse method for determining parameters of the consequent of fuzzy rules.

II. Research Method

The data used in this study were 120 mammograms a secondary data extraction results obtained from the image database Mammographic Image Analysis Society (MIAS) through the website http://peipa.essex.ac.uk/pix/mias. The data have previously been used by [8]. Based on the data of 120 mammograms were used in this study were divided into two, namely 96 training data and 24 testing data. Step-by-step analysis of the data presented in Figure 1.

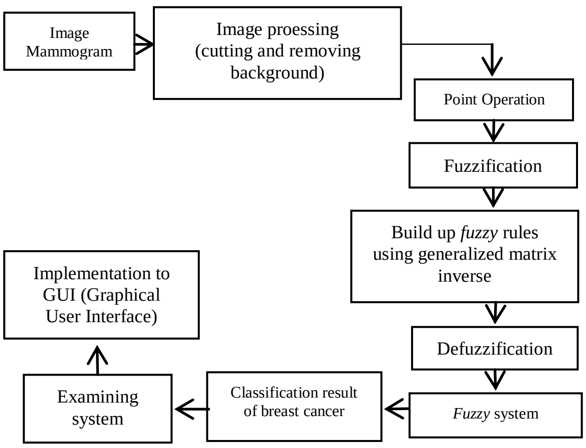

FIGURE 1. Step Study Chart

After the built fuzzy system has good accuracy, the next step is to create the look of the system with a GUI (Graphical User Interface) so that the display system will be more attractive. The initial design GUI (Graphical User Interface) for breast cancer shown by Figure 2.

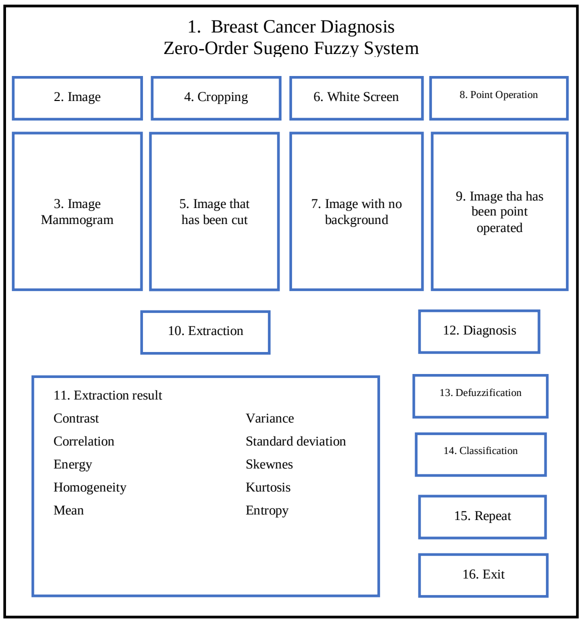

FIGURE 2. PRELIMINARY DRAFT GUI DISPLAY

III. DISCUSSION

The data used in this study is the mammogram image data that has previously been done image processing includes cutting, elimination of background and image enhancement with point operation. Image data that has been operated on point then extracted image so as to obtain 10 feature extractions, ie contrast, correlation, energy, homogeneity, mean, variance, standard deviation, skewnes, kurtosis, and entropy. Ten feature extractions are used as input variables. While the output variables used in this study was 3, which normally, benign and malignant. Image processing to obtain the extracted image has been done by [8].

A. Fuzzification

The next stage identifies the set of rules of input and output. To input a set of rules drawn from the minimum value and a maximum value of data from each extraction. The set of rules for each input that contrast = [0.134 0.235], correlation = [0.955 0.989], energy = [0.123 0.639], homogeneity = [0.939 0.979], mean [127.6 234], variance = [1973 7827], standard deviation = [44.42 88.47], skewnes = [-3.121 0.71], kurtosis = [1.36 13.13], entropy = [2.995 7.394]. While the output set of rules is in the interval [1 3]. One for normal, 2 for the benign, and 3 for malignant. Then define a fuzzy set for each input variable with 9 fuzzy set and is represented by gauss curve. Gauss curve representation for variable contrast is shown in Figure 3.

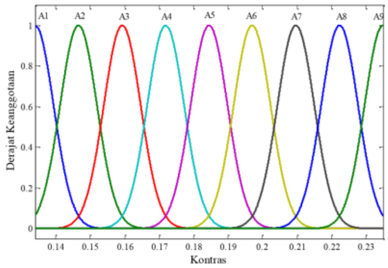

FIGURE 3. REPRESENTATION OF A SET OF FUZZY VARIABLE CONTRAST

B. Constructing Fuzzy Rules

Each value of the extracted image sought of the degree membership to the largest degree of membership then used to build the rules. The value of greatest degree of membership has been obtained from the respective image extraction feature are grouped in each variable fuzzy set membership degree input. The following is the result of the first training data and groupings in the fuzzy set.

TABEL 1. RESULT DATA EXTRACTION AND CLASSIFICATION 1 OF FUZZY INPUT IN SET

Image feature	Extraction result	Degree of membership	*Fuzzy* set
Contrast (x_1)	0,17765	0,562596	A_4
Correlation (x_2)	0,97352	0,701475	B_5
Energy (x_3)	0,26932	0,818787	C_3
Homogeneity (x_4)	0,96044	0,794505	D_5
Mean (x_5)	202,629	0,636253	E_7
Variance (x_6)	4336,078	0,86388	F_4
Standard deviation(x_7)	65,8489	0,968546	G_5
Skewnes (x_8)	-1,2388	0,977081	H_5
Kurtosis (x_9)	3,7231	0,650041	I_3
Entropy (x_{10})	5,5838	0,790291	J_6
Diagnosis			Normal

Thus the rules established for training data number 1 are as follows:

[Rule 1] If contrast is A_4 and correlation is B_5 and energy is C_3 and homogeneity is D_5 and mean is E_7 and variance is $F_4$and standard deviation is G_5 and skeunes is H_5 and kurtosis is I_3 and entropy is J_6 then the diagnosis is normal.

Using the same way to calculate and classify for another 95 data extraction result so that based on 96 training data which are used to construct system can be formed 96 fuzzy rules. This rule has been formed by [8]. Once obtained fuzzy ruels the next step is evaluating those rules in fuzzy rules of zero order Sugeno.

The form of fuzzy rules zero order of Sugeno is:

$$IF\ (x_1\ is\ A_{i1}\ ) \circ \ldots \circ (x_n\ is\ A_{in}\ )\ THEN\ y = k \quad (1)$$

Where k is a constant. The fuzzy rules for fuzzy rules zero order system of sugeno become

[Rule 1] If the contrast is A_4 and correlation is B_5 and energy is C_3 and homogeneity is D_5 and mean is E_7 and variance is F_4 and standard deviation is G_5 and skewnes is H_5 and kurtosis is I_3 and entropy is J_6 then $y_1 = k_1$.

[Rule 2] If the contrast is A_4 and correlation is B_5 and energy is C_3 and homogeneity is D_5 and mean is E_7 and variance is $F_4$and standard deviation is G_4 and skewnes is H_5 and kurtosis is I_3 and entropy is J_6 then $y_2 = k_2$.

⋮

[Rule 96] If the contrast is A_5 and correlation is B_6 and energy is C_2 homogeneity is D_5 d and mean is E_2 and variance is F_5 and variance is G_6 and skewnes is H_8 and kurtosis is I_2 and entropy is J_7 then $y_{96} = k_{96}$. When $k_1, k_2, \ldots, k_{96}$ are real constants which are going to be estimated. The process of determining k value using the method of generalized matrix inverse.

C. Defuzzification

The process of defuzzification in this resarch using the method of weight average with formula [10]:

$$y = \frac{\sum_{i=1}^{L} y_i(\mu_{i1}(x_1)\mu_{i2}(x_2)\ldots\mu_{in}(x_n))}{\sum_{i=1}^{L}\mu_{i1}(x_1)\mu_{i2}(x_2)\ldots\mu_{in}(x_n)} = \frac{\sum_{i=1}^{L} k_i(\mu_{i1}(x_1)\mu_{i2}(x_2)\ldots\mu_{in}(x_n))}{\sum_{i=1}^{L}\mu_{i1}(x_1)\mu_{i2}(x_2)\ldots\mu_{in}(x_n)} \quad (2)$$

The (3) equation can be stated as

$$y = \sum_{i=1}^{L} w_i k_i \quad (3)$$

where

$$w_i = \frac{\mu_{i1}(x_1)\mu_{i2}(x_2)\ldots\mu_{in}(x_n)}{\sum_{i=1}^{L}\mu_{i1}(x_1)\mu_{i2}(x_2)\ldots\mu_{in}(x_n)} \quad (5)$$

Then, variable of k can be sought by minimizing the function of

$$J = \sum_{k=1}^{N}\big(d(t) - y(t)\big)^2 = (d - Xk)^T(d - Xk) \quad [11] \quad (6)$$

Where d is the real *output* represented by matrix

$N \times 1$ (N the number of data) $d = \begin{bmatrix} d(1) \\ d(2) \\ \vdots \\ d(96) \end{bmatrix}$.

X is the matrix with size $N \times L$, where L is the amount of formed fuzzy rules.

$$X = \begin{bmatrix} w_1(1) & w_2(1) & \cdots & w_{96}(1) \\ w_1(2) & w_2(2) & \cdots & w_{96}(2) \\ \vdots & \vdots & \vdots & \vdots \\ w_1(96) & w_2(96) & \cdots & w_{96}(96) \end{bmatrix}$$

While k is the real constant that is going to be sought represented by $k = \begin{bmatrix} k_1 \\ k_2 \\ \vdots \\ k_{96} \end{bmatrix}$, a matrix in size $L \times 1$. The J function will reach the minimum value if

$$d - Xk = 0 \text{ or } Xk = d \quad (7)$$

Then, can be determined parameter k using generalized matrix inverse [12]:

$$k = X^+ d \quad (8)$$

Where $X^+ = V\Sigma^+U^T$is generalized matrix inverse from matrix X. The variable U is orthogonal matrix $m \times m$. V is orthonormal matrix $n \times n$, and Σ is matrix $m \times n$ which all entries on the diagonal is a singular entri value where zero beyond the diagonal [12]. Based on the steps above will be obtained constants k as follows

$$k = \begin{bmatrix} 0 \\ \vdots \\ 1{,}4283 \\ \vdots \\ -0{,}0119 \\ \vdots \\ 0 \end{bmatrix}$$

Then k constant substitutable in 96 rules and gained rules for the training data number -1:

[Rule 1] If the contrast is A_4 and correlation is B_5 and energy is C_3 and homogeneity is D_5 and mean is E_7 and variance is F_4 and standard deviation is G_5 and skewnes is H_5 and kurtosis is I_3 and entropy is J_6 then $y_1 = 0$.

Further for the process of defuzzification can be calculated using equation (2). Once obtain the value of defuzzification, can be done a testing system to get accuracy level, ie: accuracy, sensitivity, and specification. The formula for the accuracy level [13]:

$$accuracy = \frac{the\ number\ of\ the\ correct\ data}{the\ amount\ of\ entirely\ data} \times 100\% \quad (9)$$

$$sensitivity = \frac{TP}{TP+FN} \times 100\% \quad (10)$$

$$specification\ \frac{TN}{TN+FP} \times 100\% \quad (11)$$

D. Result

Based on the defuzzification process done toward the train data achieved the classification result of breast cancer TP=64, TN=32, FP=0, and FN=0. Thus can be calculated the accuracy level from the training data which are the accuracy, sensitivity, and specification 100%. Whereas for the test data achieved the result of accuracy, sensitivity, and specification of the test data 50%, 77,7% dan 66,67%.

The accuracy obtained from mamdani fuzzy system had been done by [8] up to 96,875% and 100% for sensitivity and specification on the training data. For the test data in mamdani fuzzy system are up to 91,67%; 93,75%, and 87,5% for accuracy, sensitivity, and specification . The comparison of the classification result from both fuzzy systems shown at Table 2.

TABEL 2. COMPARISON OF THE RESULT ZER0-ORDER SUGENO FUZZY SYSTEM TO THE MAMDANI FUZZY SYSTEM

Examining system		*Fuzzy* system	
		Zero-order Sugeno	Mamdani
Training Data	Accuracy	100%	96,875%
	Sensitivity	100%	100%
	Specification	100%	100%
Test Data	Accuracy	50%	91,67%
	Sensitivity	77,7%	93,75%
	Specification	66,67%	87,5%

E. Implementation with GUI

The last stage in this research is the application GUI (Graphical User Interface) on a fuzzy system that has been built in order that the look of fuzzy system more attractive and interactive for users. Results GUI for all training data number -1 with normal early early diagnosis is shown in Figure 4.

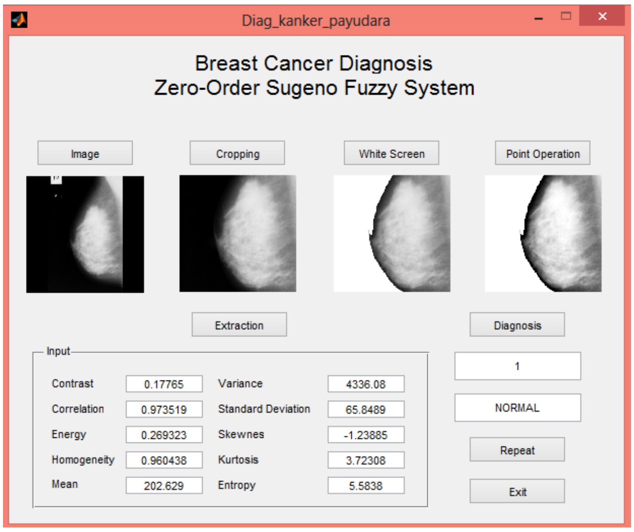

FIGURE 4. GUI DISPLAY RESULT OF TRAIN DATA 1

Figure 4 shows the classification results for the training data 1. In the column showing the image of the original image, the column cuts and a white background is an image that has been cut and removed her black background and then do the operation point on the operation point of the column. After the surgery performed extraction point in the image. Based on the extracted image is then calculated defuzzification value and classified the results. Based on Figure 4 shows that the results of data classification 1 is normal practice that has been in accordance with the initial diagnosis.

IV. CONCLUSION

The steps in constructing a zero-order Sugeno fuzzy system that starts with image processing to obtain extraction mammogram image, then fuzzification of data result of exctraction image. Based on training data used, will form 96 fuzzy rules in which the consequent determination of real constants do with generalized matrix inverse. Furthermore defuzzification process performed by the method of weight average. In the final stage, the system will be implemented fuzzy awoke with a GUI (Graphical User Interface) in order to see more attractive programs. Based on the level of accuracy obtained in this study it can be concluded that for the training data-order Sugeno fuzzy system is better in diagnosing breast cancer than using fuzzy system of mamdani. As for the test data is still needed improvements in order to improve accuracy.

Improvement and development that are likely to do in order to obtain better results of which add input variables besides extraction features such as age, weight, and quality of mammography tool that will affect the quality of the resulting image. It also adds the classification at the output, as is normal, stage 1, stage 2, stage 3 and stage 4. Furthermore, it can also make the selection of 10 extraction image is used as input to improve the accuracy and use other methods in determining the consequent parameters so that it can further optimize the results obtained.

Global Stability of SACR Epidemic Model for Hepatitis C on Injecting Drug Users

Dwi Lestari[1], Lidyana Candrawati[2]
[1,2]Mathematics Education Department, Yogyakarta State University
dwilestari.math@gmail.com; dwilestari@uny.ac.id ; lidyana.elcha@gmail.com

Abstract— This study aims to analyze SACR model of epidemics of hepatitis C on injecting drug users. This model is represented by a system of nonlinear differential equations based on model that written by Kretzschmar M, Wiessing L (2004). In this paper will be discussed detail about the global stability of the disease free equilibrium point. The analysis results obtained to equilibrium points that is disease free and endemic equilibrium point. The Disease-free equilibrium point is local asymptotically stable if the basic reproduction number is less than one, and it is global asymptotically stable if the basic reproduction number is less than or equal to one. It means that for a long period of time, the infected population will decrease or even disappear so that the virus no longer exists in the population. Meanwhile, for the basic reproduction number is more than one, the disease-free equilibrium point is unstable and the endemic equilibrium point is local asymptotically stable. This shows that for a certain period, the Hepatitis C virus will be persist. Furthermore, based on the simulation of this model, it is found that the higher the average frequency of the use of needles together in injecting drug users, the more of the proportion of acute infection, chronic carriers and recovered. While the proportion of susceptible decreased.

Keywords: *Hepatitis C, injecting drug users, the SACR model, equilibrium points, global stability.*

I. INTRODUCTION

Epidemic models commonly used in analyzing the spread of disease is a SIR model. Based on its characteristics, this model classifying the population into three subpopulations. They are susceptible (groups of individuals free infected disease), infected (groups of individuals infected disease), and recovered (group of individuals who have been cleared of the disease). In certain diseases, some infected individuals can develop into chronic, so they need for a developing model that is able to accommodate the characteristics of the disease, such as adding a group such as carrier subpopulation.

On carrier states, susceptible individuals can be infected by contact with acute infection individual and carrier individual. Acute infection individual in a period will be recovered totally by itself, or it can be developed into a carrier virus. [1]

One of the disease which can be analyzed with the model SACR is the spread of Hepatitis C. Generally, this model can be applied to the spread of Hepatitis C because of an individual with acute infection Hepatitis C virus can be develop into chronic Hepatitis or will recovery by itself (though in small percentage). In this study the spread of Hepatitis C is focused on injecting drug user community. This is because the percentage of the case is high.

Based on the World Health Organization (WHO) data in 2009 [2], it is estimated that seven million people in Indonesia suffer Hepatitis C virus and thousands of new infections occur annually, but 90% of people are not aware of that condition. The disease can be transmitted through blood contact between individuals, and the highest risk occurs when using injecting together among drug users community. In Indonesia, the prevalence of HCV among injecting drug users reached 77.3%. [3]

Some references that support this research are project research about epidemic model with carrier population by Maia Martcheva and Carlos Castillo-Chavez (2003) [4] entitled *Diseases with chronic stage in a population with varying size*. Research about *Modelling the transmission of hepatitis C in injecting drug users* has been done by M.Kretzschmar and L. Wiessing (2004) [5]. And Dontwi, et al (2010) [6] *Mathematical modeling of Hepatitis C Virus transmission among injecting drug users and the*

ISBN 978-602-74529-0-9

impact of vaccination. In this research will be discussed about stability analyzis of the disease free equilibrium point using a model that is developed by M. Kretzschmar and L. Wiessing (2004) [5].

II. MODEL FORMULATION

Individuals will be entered into the population because of their birth or their recruitment and leave the population through death or emigration. The total population is all individuals are susceptible, infected by hepatitis C virus or who have been recovered from hepatitis C. In this case, in susceptible individuals infected are injecting drug users. The rate of recruitment of new injecting drug users determine raising of susceptible individuals (injecting drug users) in the population. Individuals are easy to be infected with hepatitis C acute when contact with an infected individual acute or chronic. The infection rate is influenced by how often the contacts or share needles among injecting drug users. Individuals are more likely to use inject together will be more at risk to be infected with hepatitis C. Patients with hepatitis C are in the acute phase of approximately 6-10 weeks. Most people with acute infection will develop into chronic, whereas the part of them will recoverl by themself. Patients with acute hepatitis C will develop chronic liver within 15-20 years, or can also be liver cancer after 20-30 years, or it will die. Almost all of mortality from patients with hepatitis C-related complications of cirrhosis and liver cancer, so mortality due to hepatitis C virus infection is very small.

In this study, the human population at time *t* divided into four subpopulations. They are susceptible, acute infection, chronic carrier (chronically infected), and recovered (free of hepatitis C).

To simplify the model is given the following assumptions:

1. The population is constant and closed,
2. The population is homogeneous, it means that everyone has the same risk for infected the virus and the frequency of use inject together (non-sterile) is constant,
3. Individuals who haven’t been infected disease include susceptible class,
4. The mortality due to hepatitis C virus infection is ignored and it just happened natural mortality in each subpopulation.
5. Individuals who have recovered from hepatitis C, will not be infected again and become have immune to the virus Hepatitis C.

The variables and parameters which used in this study:

$S(t)$: The number of *susceptible* individuals
$A(t)$: The number of *acute infection* individuals
$C(t)$: The number of *chronic carrier* individuals
$R(t)$: The number of *recovered* individuals
$N(t)$: Total populations
B: The rate of recruitment
λ: The rate of infection
κ: Average frequency of use inject (needles) together
b_a: Probability transmission as a result of contact between susceptible individuals to acute infection individuals
b_c: Probability transmission as a result of contact between susceptible individuals with chronic individual carrier
μ: Natural mortality rate
σ_1: Individual transfer rate of acute infection becomes chronic individual carrier
σ_2: Individual transfer rate of chronic carrier into individual Recovered
ρ: The proportion of acute infection who become chronic carriers
$(1-\rho)$: The proportion of acute infection is completely cured

with $S(t), A(t), C(t), R(t) \geq 0$ *and* $B, \lambda, \kappa, b_a, b_c, \mu, \sigma_1, \sigma_2, \rho, (1-\rho) > 0$.

Based on the characteristics and the assumptions, the spread of hepatitis C can be described in the following flow chart:

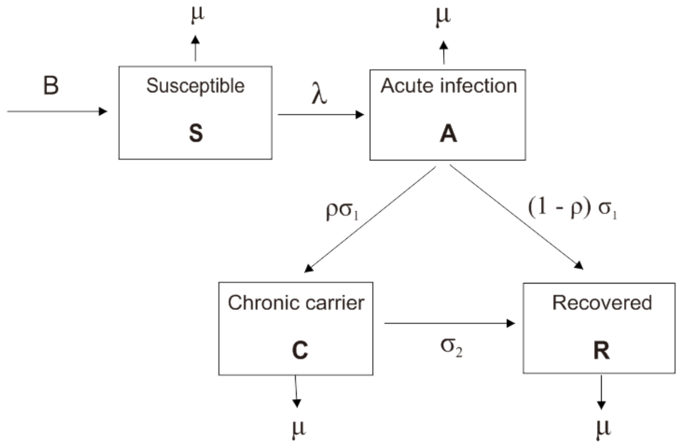

Figure 1. Flow diagram of the spread of hepatitis C in injecting drug users

Of the flow chart above, obtained by differential equations system is a model the spread of hepatitis C in injecting drug users. [5]

$$\frac{dS(t)}{dt} = B - \lambda S(t) - \mu S(t)$$
$$\frac{dA(t)}{dt} = \lambda S(t) - \sigma_1 A(t) - \mu A(t) \qquad (1)$$
$$\frac{dC(t)}{dt} = \rho\sigma_1 A(t) - \sigma_2 C(t) - \mu C(t)$$
$$\frac{dR(t)}{dt} = (1-\rho)\sigma_1 A(t) + \sigma_2 C(t) - \mu R(t)$$

with $\lambda(t) = \kappa\left(b_a \frac{A(t)}{N(t)} + b_c \frac{C(t)}{N(t)}\right)$ and $N = \frac{B}{\mu}$

Furthermore, to simplify the system, set up a proportion which compares the number of individuals in a subpopulation with the number of total population, we get

$$\frac{ds}{dt} = \mu - \lambda(t)s(t) - \mu s(t)$$
$$\frac{da}{dt} = \lambda(t)s(t) - \sigma_1 a(t) - \mu a(t) \qquad (2)$$
$$\frac{dc}{dt} = \rho\sigma_1 a(t) - \sigma_2 c(t) - \mu c(t)$$
$$\frac{dr}{dt} = (1-\rho)\sigma_1 a(t) + \sigma_2 c(t) - \mu r(t)$$

with $\lambda(t) = \kappa\big(b_a a(t) + b_c c(t)\big)$.

In this model use a parameter stating the expected value of a new case caused by infected individuals in a population of susceptible individuals. These parameters are the basic reproduction number (R_0). Based on the model (2) defined parameter

$$R_0 = \kappa\left(\frac{b_a}{(\sigma_1+\mu)} + b_c \frac{\rho\sigma_1}{(\sigma_2+\mu)(\sigma_1+\mu)}\right).$$

III. EQUILIBRIUM POINT MODEL ANALYSIS

These are equilibrium points of the system (2) are described in **theorem 1**.

Theorem 1.

(i) If $a = 0$ *then system (2) has an equilibrium point that is disease-free,* $E_0 = (s, a, c, r) = (1,0,0,0)$.

(ii) If $a \neq 0$ then system(2) has the endemic equilibrium point $E_1 = (\hat{s}, \hat{a}, \hat{c}, \hat{r})$.

Proof:

The *(s,a,c,r)* point is the equilibrium point system (2) if $\frac{ds}{dt} = \frac{da}{dt} = \frac{dc}{dt} = \frac{dr}{dt} = 0$ [7]. System (2) can be written as

$$\begin{aligned} &\mu - \lambda s - \mu s = 0 && (2a) \\ &\lambda s - \sigma_1 a - \mu a = 0 && (2b) \\ &\rho\sigma_1 a - \sigma_2 c - \mu c = 0 && (2c) \\ &(1-\rho)\sigma_1 a + \sigma_2 c - \mu r = 0 && (2d) \end{aligned}$$

with $\lambda(t) = \kappa(b_a a + b_c c)$.

(i) If $a = 0$, then from equation (2c) is obtained $c = 0$. If $a = 0$ dan $c = 0$ are substituted into the equation (2a) and (2d) obtained $s = 1$ dan $r = 0$. This proves that the disease-free equilibrium point is $E_0 = (1,0,0,0)$.

(ii) If $a \neq 0$ (which symbolized by $\hat{a}$), then the equation (2c) becomes $\rho\sigma_1\hat{a} - \sigma_2\hat{c} - \mu\hat{c} = 0$ or $\hat{c} = \frac{\rho\sigma_1}{(\sigma_2+\mu)}\hat{a}$. Furthermore, if the equation $\hat{c}$ is substituted into the equation (2b) obtained $\hat{s} = \frac{(\sigma_1-\mu)}{\kappa\left(b_a+b_c\frac{\rho\sigma_1}{(\sigma_2+\mu)}\right)}$. Consequently, from equation (2a) is obtained $\hat{a} = \frac{\mu\left(\kappa\left(b_a+b_c\frac{\rho\sigma_1}{(\sigma_2+\mu)}\right)-(\sigma_1+\mu)\right)}{\kappa\left(b_a+b_c\frac{\rho\sigma_1}{(\sigma_2+\mu)}\right)(\sigma_1+\mu)}$. Then from equation (2d) is obtained $\hat{r} = \left(\frac{(1-\rho)\sigma_2+\mu}{\mu(\sigma_2+\mu)}\right)\sigma_1\hat{a}$. So, this proves that the endemic equilibrium point is $E_1 = (\hat{s}, \hat{a}, \hat{c}, \hat{r})$ with

$$\hat{s} = \frac{(\sigma_1+\mu)}{\kappa\left(b_a + b_c\frac{\rho\sigma_1}{(\sigma_2+\mu)}\right)}; \quad \hat{a} = \frac{\mu\left(\kappa\left(b_a + b_c\frac{\rho\sigma_1}{(\sigma_2+\mu)}\right) - (\sigma_1+\mu)\right)}{\kappa\left(b_a + b_c\frac{\rho\sigma_1}{(\sigma_2+\mu)}\right)(\sigma_1+\mu)}$$

$$\hat{c} = \frac{\rho\sigma_1}{(\sigma_2+\mu)}\hat{a}; \quad \hat{r} = \frac{(\sigma_2+(1-\rho)\mu)\sigma_1}{\mu(\sigma_2+\mu)}\hat{a}.$$

IV. STABILITY ANALYSIS OF EQUILIBRIUM POINTS

In this section, will be described analysis of global stability of the equilibrium point of system (2). The stability of the equilibrium point system (2) is presented in Theorem 2, Theorem 3 and Theorem 4 as follow

Theorem 2.

(i) If $R_0 < 1$ then the disease-free equilibrium point $E_0 = (s,a,c,r) = (1,0,0,0)$ is local asymptotically stable and

(ii) If $R_0 > 1$ then the disease-free equilibrium point $E_0 = (s,a,c,r) = (1,0,0,0)$ is unstable.

Proof

The Jacobian matrix of the system (2) around the equilibrium point is $E_0 = (1,0,0,0)$ is

$$J(E_0) = \begin{bmatrix} -\kappa(b_a a + b_c c) - \mu & -\kappa b_a s & -\kappa b_c s & 0 \\ \kappa(b_a a + b_c c) & \kappa b_a s - \sigma_1 - \mu & \kappa b_c s & 0 \\ 0 & \rho\sigma_1 & -\sigma_2 - \mu & 0 \\ 0 & (1-\rho)\sigma_1 & \sigma_2 & -\mu \end{bmatrix} \qquad (3)$$

The characteristic equation of the (3) can be searched by specifying $det(J(E_0) - \gamma I) = 0$, with γ is eigenvalue and I is the identity matrix. Thus obtained:

$$(\gamma+\mu)^2\left(\gamma^2 + \left(-\kappa b_a + (\sigma_2+\mu) + (\sigma_1+\mu)\right)\gamma - \rho\sigma_1\kappa b_c - \kappa b_a(\sigma_2+\mu) + (\sigma_2+\mu)(\sigma_1+\mu)\right) = 0. \qquad (4)$$

The equation (4) can be written as

$$(\gamma+\mu)^2(\gamma^2 + q_1\gamma + q_2) = 0$$

with

$$q_1 = -\kappa b_a + (\sigma_2+\mu) + (\sigma_1+\mu)$$
$$q_2 = -\rho\sigma_1\kappa b_c - \kappa b_a(\sigma_2+\mu) + (\sigma_2+\mu)(\sigma_1+\mu).$$

Based on the equation (4), it is obtained eigenvalues$\gamma_1 = \gamma_2 = -\mu$. For other eigenvalues, Routh-Hurwitz criteria used to expand the type of stability of the characteristic equation [8]

$$\gamma^2 + q_1\gamma + q_2 = 0. \tag{5}$$

The equation$q_1 = -\kappa b_a + (\sigma_2 + \mu) + (\sigma_1 + \mu)$can be expressed as

$$q_1 = \frac{b_a(\sigma_1 + \mu)(\sigma_2 + \mu)(1-R_0) + (\sigma_2 + \mu)(b_a(\sigma_2 + \mu) + b_c\rho\sigma_1) + b_c\rho\sigma_1(\sigma_1 + \mu)}{b_a(\sigma_2 + \mu) + b_c\rho\sigma_1}$$

Furthermore, the equation $q_2 = -\rho\sigma_1\kappa b_c - \kappa b_a(\sigma_2 + \mu) + (\sigma_2 + \mu)(\sigma_1 + \mu)$ can be expressed as $q_2 = (R_0 + 1)(\sigma_1 + \mu)(\sigma_2 + \mu)$.

It is known that$R_0 < 1$, then$q_1 > 0$ and$q_2 > 0$. Based on Routh Hurwitz criteria, zero maker from the equation (5) will be negative if $\mathrm{q}_1 > 0$ and $\mathrm{q}_2 > 0$. This shows that all eigenvalues of equation (4) isnegative, so that the disease-free equilibrium point $\mathrm{E}_0 = (1,0,0,0)$is islocal asymptotically stable.

Meanwhile, if known$R_0 > 1$, then it is obtained$q_2 < 0$. The roots of the equation (5) will be different from that mark$\gamma_1 < 0$ and$\gamma_2 > 0$or the opposite. Thus, it can be said that if$R_0 > 1$, then the equation (4) has a positive eigenvalues. Therefore, the disease-free equilibrium point $E_0 = (s, a, c, r) = (1,0,0,0)$is unstable.

Theorem 3.
If $R_0 \le 1$ *then disease-free equilibrium point* $E_0 = (s, a, c, r) = (1,0,0,0)$ *is global asymptotically stable.*
Proof.

To express the global stability of the disease-free equilibrium point, it will be shown $s(t) \to 1$, $a(c) \to 0$, $c(t) \to 0$, $r(t) \to 0$ at time $t \to \infty$. Firstly, determine solutions of differential equations in system (2).

The second equation solution of the system (2) is

$$a(t) = e^{-(\sigma_1+\mu)t} \int e^{(\sigma_1+\mu)t}\lambda(t)s(t)\,dt + a_0e^{-(\sigma_1+\mu)t}$$

Because$0 \le s(t) \le 1$, then

$$\begin{aligned} a(t) &\le e^{-(\sigma_1+\mu)t} \int e^{(\sigma_1+\mu)t}\lambda(t)\,dt + a_0e^{-(\sigma_1+\mu)t} \\ &= \int_0^t e^{-(\sigma_1+\mu)(t-\tau)}\lambda(\tau)\,d\tau + a_0e^{-(\sigma_1+\mu)t} \end{aligned}$$

Furthermore, by taking lim sup for $t \to \infty$ [9], it is obtained

$$\begin{aligned} \limsup_{t\to\infty} a(t) &\le \limsup_{t\to\infty} \int_0^t e^{-(\sigma_1+\mu)\tau}\lambda(t-\tau)\,d\tau \\ &\le \limsup_{t\to\infty} \lambda(t) \int_0^\infty e^{-(\sigma_1+\mu)\tau}\,d\tau \\ &= \frac{1}{(\sigma_1 + \mu)} \limsup_{t\to\infty} \lambda \,(6) \end{aligned}$$

Then determined solutions to a third equation of the system (2) that

$$c(t) = \rho\sigma_1e^{-(\sigma_2+\mu)t} \int e^{(\sigma_2+\mu)t}a\,dt + c_0e^{-(\sigma_2+\mu)t}$$

Furthermore, by taking lim sup for$t \to \infty$, it is obtained

$$\begin{aligned} \limsup_{t\to\infty} c(t) &\le \rho\sigma_1 \limsup_{t\to\infty} \int_0^t e^{-(\sigma_2+\mu)\theta}a(t-\theta)\,d\theta \\ &\le \rho\sigma_1 \limsup_{t\to\infty} a\,(t) \int_0^\infty e^{-(\sigma_2+\mu)\theta}\,d\theta \\ &= \frac{\rho\sigma_1}{(\sigma_2 + \mu)} \limsup_{t\to\infty} a\,(t). \end{aligned} \tag{7}$$

Then inequality (6) is substituted into the inequality (7) is obtained

$$\limsup_{t\to\infty} c(t) \le \frac{\rho\sigma_1}{(\sigma_1 + \mu)(\sigma_2 + \mu)} \limsup_{t\to\infty} \lambda(t) \tag{8}$$

Then we wil discuss the rate of hepatitis C virus infection. It will be demonstrated that $\lim_{t\to\infty} \sup \lambda(t) = 0$, by taking lim sup for$t \to \infty$, then

$$\lim_{t\to\infty}\sup\lambda(t) = \lim_{t\to\infty}\sup\left(\kappa\left(b_a a(t) + b_c c(t)\right)\right).$$

Substitution inequality (6) and (8) into the above equation is obtained

$$\begin{aligned}\lim_{t\to\infty}\sup\lambda &\le \kappa b_a\frac{1}{(\sigma_1+\mu)}\lim_{t\to\infty}\sup\lambda(t) + \kappa b_c\frac{\rho\sigma_1}{(\sigma_1+\mu)(\sigma_2+\mu)}\lim_{t\to\infty}\sup\lambda(t)\\ &= \left(\frac{\kappa b_a}{(\sigma_1+\mu)} + \frac{\kappa b_c\rho\sigma_1}{(\sigma_1+\mu)(\sigma_2+\mu)}\right)\lim_{t\to\infty}\sup\lambda\\ &= R_0\lim_{t\to\infty}\sup\lambda.\end{aligned}$$

then

$$\lim_{t\to\infty}\sup\lambda \le R_0\lim_{t\to\infty}\sup\lambda$$

$$\lim_{t\to\infty}\sup\lambda - R_0\lim_{t\to\infty}\sup\lambda \le 0$$

$$\lim_{t\to\infty}\sup\lambda\,(1-R_0) \le 0.$$

as it is known$R_0 \le 1$, then $\lim_{t\to\infty}\sup\lambda = 0$.

Furthermore, with $\lim_{t\to\infty}\sup\lambda = 0$, Then based inequalities (5) and (8) were obtained $\lim_{t\to\infty}\sup a(t) = 0$ dan $\lim_{t\to\infty}\sup c(t) = 0$

And then determined the solution to fourth equations of the system (2) that is

$$r(t) = (1-\rho)\sigma_1\int_0^t e^{-\mu\omega}a(t-\omega)\,d\omega + \sigma_2\int_0^t e^{-\mu\omega}c(t-\omega)\,d\omega + r_0e^{-\mu t}$$

Furthermore, by taking lim sup for$t\to\infty$, it is obtained

$$\begin{aligned}\lim_{t\to\infty}\sup\ r(t) &\le (1-\rho)\sigma_1\lim_{t\to\infty}\sup\int_0^t e^{-\mu\omega}a(t-\omega)\,d\omega + \sigma_2\lim_{t\to\infty}\sup\int_0^t e^{-\mu\omega}c(t-\omega)\,d\omega\\ &\le \frac{(1-\rho)\sigma_1}{\mu}\lim_{t\to\infty}\sup\ a(t) + \frac{\sigma_2}{\mu}\lim_{t\to\infty}\sup c(t) \qquad (9)\end{aligned}$$

Because $\lim_{t\to\infty}\sup\ a(t) = \lim_{t\to\infty}\sup\ c(t) = 0$, then from inequality (9) is obtained $\lim_{t\to\infty}\sup\ r(t) = 0$. Thus obtained that $\lim_{t\to\infty}a(t) = 0$, $\lim_{t\to\infty}c(t) = 0$ and $\lim_{t\to\infty}r(t) = 0$.

It is known that$s(t) + a(t) + c(t) + r(t) = 1$, by taking the limit value $t\to\infty$, then obtained

$$\lim_{t\to\infty}\left(s(t) + a(t) + c(t) + r(t)\right) = \lim_{t\to\infty}1$$

$$\lim_{t\to\infty}s(t) + \lim_{t\to\infty}a(t) + \lim_{t\to\infty}c(t) + \lim_{t\to\infty}r(t) = 1$$

Because $\lim\limits_{t\to\infty}a\,(t) = 0, \lim_{t\to\infty}c(t) = 0$, and$\lim_{t\to\infty}r(t) = 0$ then$\lim_{t\to\infty}s(t) = 1.$Thus it is proved for$R_0 \le 1$then the disease-free equilibrium point $E_0 = (1,0,0,0)$ is global asymptotically stable.

Theorem 4

If $R_0 > 1$ then the endemic equilibrium point $E_1 = (\hat{s},\hat{a},\hat{c},\hat{r})$is local asymtotically stable.

Proof:

Jacobian matrix of the system (2) around the equilibrium point$E_1 = (\hat{s},\hat{a},\hat{c},\hat{r})$ is

$$J(E_1) = \begin{bmatrix} -\kappa(b_a\hat{a}+b_c\hat{c})-\mu & -\kappa b_a\hat{s} & -\kappa b_c\hat{s} & 0\\ \kappa(b_a\hat{a}+b_c\hat{c}) & \kappa b_a\hat{s}-\sigma_1-\mu & \kappa b_c\hat{s} & 0\\ 0 & \rho\sigma_1 & -\sigma_2-\mu & 0\\ 0 & (1-\rho)\sigma_1 & \sigma_2 & -\mu\end{bmatrix} \qquad (10)$$

Suppose

$$x = \kappa(b_a\hat{a}+b_c\hat{c}) = \kappa\left(b_a + \frac{b_c\rho\sigma_1}{(\sigma_2+\mu)}\right)\hat{a}\,; \quad y = \kappa b_a\hat{s} = \frac{\kappa b_a(\sigma_1+\mu)}{\kappa\left(b_a + b_c\frac{\rho\sigma_1}{(\sigma_2+\mu)}\right)}$$

$$z = \kappa b_c\hat{s} = \frac{\kappa b_c(\sigma_1+\mu)}{\kappa\left(b_a + b_c\frac{\rho\sigma_1}{(\sigma_2+\mu)}\right)}; \qquad m = (\sigma_1+\mu); \qquad n = (\sigma_2+\mu)$$

then the equation (10) can be expressed as

$$J(E_1) = \begin{bmatrix} -x-\mu & -y & -z & 0\\ x & y-m & z & 0\\ 0 & \rho\sigma_1 & -n & 0\\ 0 & (1-\rho)\sigma_1 & \sigma_2 & -\mu\end{bmatrix}$$

The characteristic equation of the equation (10) can be obtained by solving $det(J(E_2) - \gamma I) = 0$, with γ is an eigen value and I is the identity matrix. Thus, it is obtained:

$$(\mu + \gamma)\big(\gamma^3 + (n + x + \mu - y + m)\gamma^2 + (xn + \mu n - yn + mn + xm - \mu x + \mu m - z\rho\sigma_1)\gamma + (xnm - \mu yn + \mu mn - \rho\sigma_1 z\mu)\big) = 0$$

or can be expressed as

$$(\mu + \gamma)(\gamma^3 + k_1\gamma^2 + k_2 y + k_3) = 0 \qquad (11)$$

with

$$k_1 = n + x + \mu - y + m$$
$$k_2 = xn + \mu n - yn + mn + xm - \mu y + \mu m - z\rho\sigma_1$$
$$k_3 = xnm - \mu yn + \mu mn - \rho\sigma_1 z\mu$$

Based on the equation (11), it is obtained eigen value $\gamma_1 = -\mu$. For the others eigenvalues, will be used Routh-Hurwitz criteria to look at the roots of the characteristic equation $(\gamma^3 + k_1\gamma^2 + k_2 y + k_3)$. By substituting *x*, *y*, *z*, *m*, *n* into the equation k_1, k_2, and k_3, it is obtained:

$$k_1 = (\sigma_2 + \mu) + \mu R_0 + \frac{\kappa b_c \rho\sigma_1}{R_0(\sigma_2 + \mu)};$$

$$k_2 = \mu R_0(\sigma_2 + \mu) + \mu(R_0 - 1)(\sigma_1 + \mu) + \frac{\mu\kappa b_c \rho\sigma_1}{R_0(\sigma_2 + \mu)};$$

$$k_3 = \mu(R_0 - 1)(\sigma_1 + \mu)(\sigma_2 + \mu)$$

Based on the criteria of Routh-Hurwitz, zero maker of the equation$\gamma^3 + k_1\gamma^2 + k_2 y + k_3 = 0$ will be negatife if $k_1, k_2, k_3 > 0$ and $\Delta_2 = k_1 k_2 - k_0 k_3 > 0$. Because it was known $R_0 > 1$, then $k_1 > 0$, $k_2 > 0$, and $k_3 > 0$. Then,

$$\begin{aligned} \Delta_2 &= k_1 k_2 - k_0 k_3 \\ &= (\sigma_2 + \mu)\left(\mu R_0(\sigma_2 + \mu) + \frac{\mu\kappa b_c \rho\sigma_1}{R_0(\sigma_2 + \mu)}\right) \\ &\quad + \left(\mu R_0 + \frac{\kappa b_c \rho\sigma_1}{R_0(\sigma_2 + \mu)}\right)\left(\mu R_0(\sigma_2 + \mu) + \mu(R_0 - 1)(\sigma_1 + \mu) + \frac{\mu\kappa b_c \rho\sigma_1}{R_0(\sigma_2 + \mu)}\right) \end{aligned}$$

Because of $R_0 > 1$, then$\Delta_2 = k_1 k_2 - k_0 k_3 > 0$.

Thus, it is obtained all eigenvalues of equation (11) is negative, so it is proved that if $R_0 > 1$, then the endemic equilibrium point $E_1 = (\hat{s}, \hat{a}, \hat{c}, \hat{r})$is local asymptotically stable.

V. MODEL SIMULATION

In this section will discusses the numerical simulation of the model to provide a simulation of the spread of hepatitis C model in injecting drug users by using MAPLE 15. Given the values of the following parameters $b_a = 0{,}3, b_c = 0{,}03$ [5], $\mu = 0{,}056$, $\frac{B}{N} = 0{,}056$, $\sigma_1 = 5, \sigma_2 = 0{,}05, \rho = 0{,}8$ and some specific initial value.

To simulate the conditions $R_0 < 1$, the value is taken $\kappa = 3$ and given initial values $s(0) = 0{,}002$, $a(0) = 0{,}008$, $c(0) = 0{,}45$, $r(0) = 0{,}54$. It is obtained,

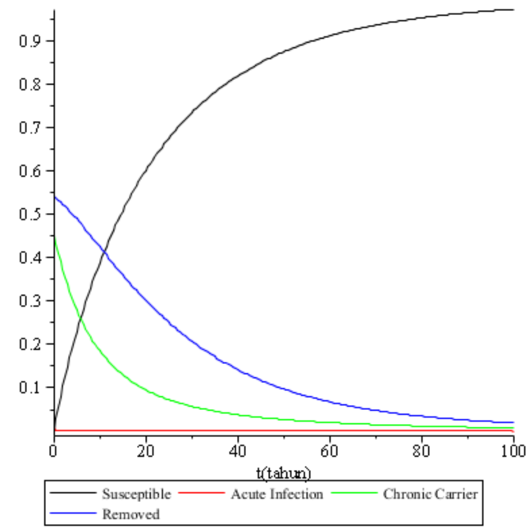

Figure 2. Simulation of the system (3.7) for$R_0 = 0{,}8497283259 < 1$

Furthermore, given also some initial values for each proportion of individuals susceptible, acute infection, chronic carrier as follows (0, 0.06, 0.015, 0.2), (0, 0.14, 0.25, 0.3), and (0, 0.49, 0.2, 0.1) to obtain a phase portrait of system solutions in the field of s, a, c. Based on these parameter values and initial values given phase portraits obtained in the field s, a, c that is shown in Figure 2.

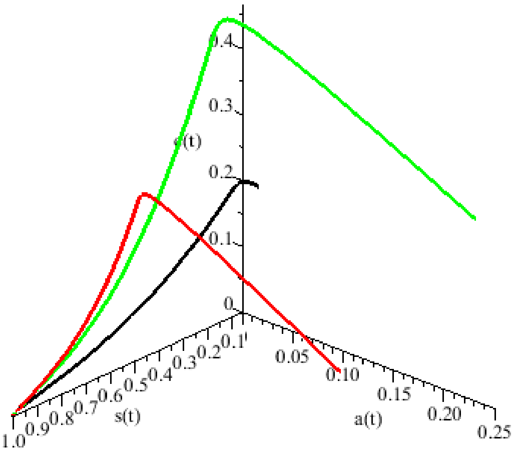

Figure3. Phase portrait in the fields,*a*,*c* for$R_0 = 0{,}8497283259 < 1$

Based on Figure 2 and Figure 3 shows that the proportion of susceptible individuals is increasing to the point 1 over time. As for the proportion of individuals acute infection, chronic (chronic carrier), and free (recovered) from Hepatitis C virus decreases towards zero. The decline in the proportion of individuals in acute infection and chronic carrier to the point of zero indicates that the proportion of individuals in acute infection and chronic carrier is die out (no infection). This simulation shows that some different initial values and when $R_0 < 1$ solution of the system (2) moves toward the equilibrium point E_0. So it can be said that when $R_0 < 1$, hepatitis C will disappear from the population.

Then, for $R_0 > 1$, given the initial value $s(0) = 0{,}8995$, $a(0) = 0{,}0005$, $c(0) = 0{,}05$, $r(0) = 0{,}05$ to obtain a phase portrait projection solutions proportion of susceptible individuals, acute infection, chronic carrier, recovered against time t as in Figure 4, Figure 5 and Figure 6.

The numerical value for E_1 when $\kappa = 6$ adalah $\hat{s} = 0{,}588423364$, $\hat{a} = 0{,}004558601980$, $\hat{c} = 0{,}1720227162$, $\hat{r} = 0{,}2349953177$. For $\kappa = 8$ obtain $\hat{s} = 0{,}4413175231$, $\hat{a} = 0{,}006187938827$, $\hat{c} = 0{,}2335071255$, $\hat{r} = 0{,}3189874126$. Meanwhile, for $\kappa = 10$ obtained $R_0 = 2{,}832427753$, $\hat{s} = 0{,}3530540184$, $\hat{a} = 0{,}007165540935$, $\hat{c} = 0{,}2703977711$, $\hat{r} = 0{,}3693826695$.

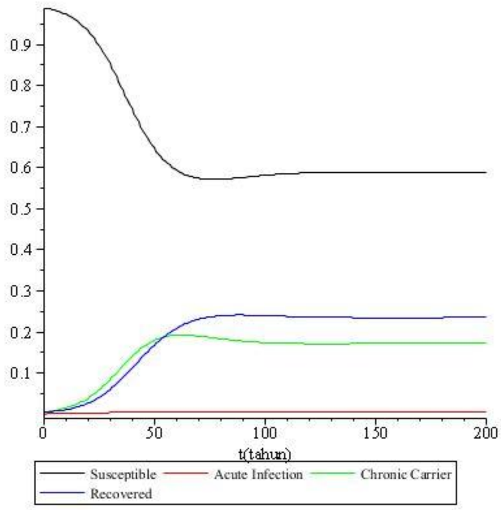

Figure 4.Simulation System (2) for$R_0 = 1{,}699456652$ with$\kappa = 6$

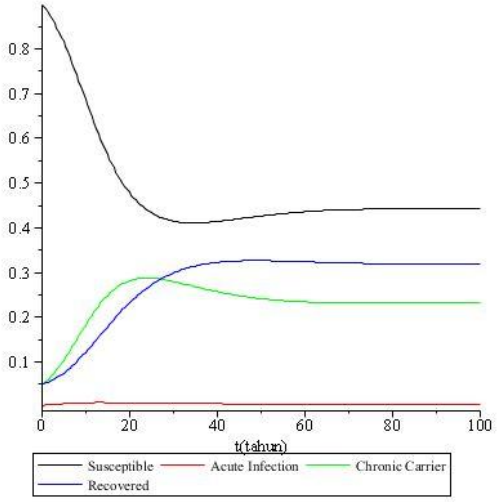

Figure 5.Simulation System (2) for$R_0 = 2{,}265942202$ with $\kappa = 8$

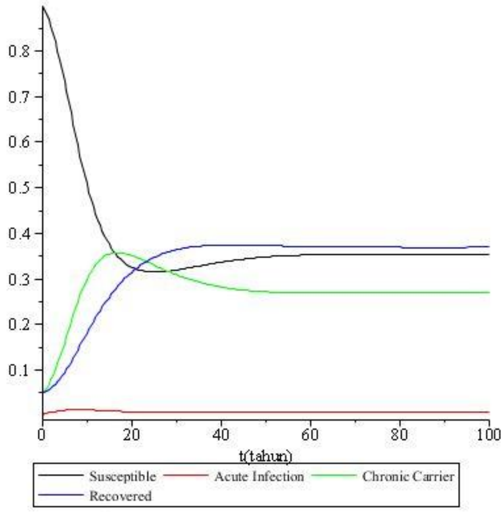

Figure 6.Simulation System (2) for$R_0 = 2{,}832427753$ with $\kappa = 10$

Furthermore, given some initial values for for each proportion of individuals susceptible, acute infection and chronic carrier are (0, 0.06, 0.015, 0.2), (0, 0.14, 0.25, 0.3), and (0, 0.49, 0.2, 0.1). To show the behavior solution of the system (2) around the endemic equilibrium point with parameter values $\kappa = 8$, can be seen in Figure 7.

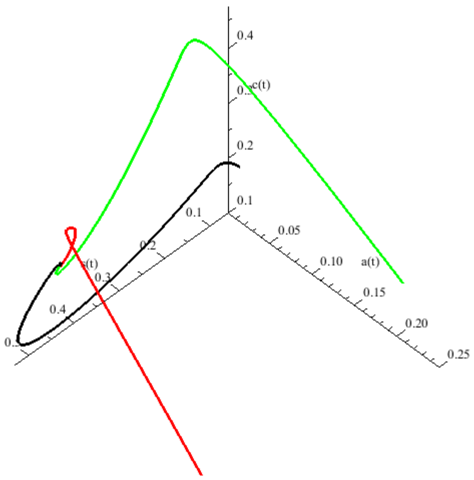

Figure 7. Phase portrait for $R_0 > 1$

Based on the simulation of Figure 4, Figure 5 and Figure 6, show that when the frequency of people using needles together (κ) is increase, the proportion of susceptible individuals decreases, while the proportion of acute infection, chronic carrier and recovered increase in proportion to the value of parameter κ. This means that if the average frequency of people using needles together is bigger, then the infection rate would be greater, which in turn resulted in the growing spread of Hepatitis C.

Based on the simulation of Figure 4, Figure 5, Figure 6 and Figure 7 shows that the proportion fluctuated. This is a result of contact individuals susceptible to hepatitis C patients with acute and chronic. When the proportion of susceptible individuals is dropped, the proportion of acute infection and chronic carrier increases and towards a point. Increasing the proportion of individuals in acute infection and chronic carrier, resulting in increased and the proportion of individuals recovered towards the equilibrium point E_1.

The solution of system (2) given initial values of different moving toward to endemic equilibrium pointE_1 and away from disease free equilibrium E_0. This means that the simulation results with the analytic results in Theorem 4 indicates that when $R_0 > 1$ the endemic equilibrium point E_1 is asymtotically stable and Theorema 2 (ii) which states that when $R_0 > 1$ the disease free equilibrium point E_0 is unstable.

VI. CONCLUSION

Based on the above discussion, it can be concluded that the model form of the spread of hepatitis C in injecting drug users is nonlinear differential equations system in first order. Furthermore, Based on model analysis, resulting the disease free equilibrium point and the endemic equilibrium pointThe spread of hepatitis C virus in injecting drug users model have the basic reproduction number R_0which is an indicator of the spread of disease. If $R_0 < 1$ then the hepatitis C virus does not attack the population or gradually disappeared, whereas if $R_0 > 1$ then the disease is endemic and is very likely to spread. In conditions of $R_0 < 1$, the disease-free equilibrium point is asymptotically stable and when $R_0 \leq 1$ is global asymtotically stable. Meanwhile, when$R_0 > 1$ the disease free equilibrium point is unstable and the endemic equilibrium point is local asymtotically stable.

The Greatest Solution of Inequality A O Kross X Less Than X Less Than B O Dot X By Using A Matrix Residuation Over An Idempotent Semiring

Eka Susilowati
Mathematics Education Departement, Universitas PGRI Adi Buana Surabaya
eka250@gmail.com

Abstract— *A complete idempotent semiring has a structure which is called a complete lattice. Because of the same structure as the complete lattice then inequality of the complete idempotent semiring can be solved a solution by using residuation theory. One of the inequality which is explained is* $A\otimes X \le B$ *where matrices A,X,B with entries in the complete idempotent semiring S. Furthermore, introduced dual product* $\odot$, *i.e. binary operation endowed in a complete idempotent semiring S and not included in the standard definition of complete idempotent semirings. A solution of inequality* $A\otimes X \le B$ *can be solved by using residuation theory. Because of the guarantee that for each isotone mapping in complete lattice always has a fixed point, then is also exist in the complete idempotent semiring. This of the characteristics is used in order to obtain the greatest solution of inequality* $A\otimes X \le X \le B\odot X$.

Keywords: complete lattice, complete idempotent semiring, dual Kleene Star, dual product, residuation theory

I. INTRODUCTION

An idempotent semirings S is a semiring which addition operation $\oplus$ is idempotent. The addition $\oplus$ and multiplication $\otimes$ have neutral elements are denoted ε and e. Idempotent semiring is said to be complete if it is closed for infinite sums and multiplication $\otimes$ distributes over infinite sums.

Because of idempotent property over its sums, idempotent semiring can be endowed ordered relation , denoted $\le$. A complete idempotent semiring has a same structure with complete lattice. Because of the same structure of its, an inequality of complete idempotent semiring can be had its solution with residuation theory.

Beside of scalar, the concept of residuation can be applied for a equality which is be explain is a inequality $A\otimes X \le B$ with matrices A, X, B with entries from a complete idempotent semiring S. A greatest solution of the inequality $A\otimes X \le B$ can be found with residuation theory. First, Baccelli (1992) research how to get the greateast solution of the inequality $A\otimes X \le B$ with matrices A ∈ $S^{n\times n}$ and X ∈ $S^{n\times 1}$. After that, the research is be continued about a greatest solution of the inequality $A\otimes X \le B$ with matrices A ∈ $S^{n\times p}$ and X ∈ $S^{p\times m}$.

As we know, the complete idempotent semiring has a property that its distributes $\otimes$ over infinite sums $\oplus$. Generally, multiplication $\otimes$ distribute over ∧ can't hold, because its just hold that a ⊗ (b ∧ c) j (a⊗b)∧ (a⊗c). The property is distribite multiplication ⊗ over ∧ in the complete idempotent semiring can be hold if its has nessesary condisition that element a has a invers, so that a ⊗ (b ∧ c) = (a ⊗ b) ∧ (a ⊗ c). With that the condition, can be defined new operation which has a property of distribute multiplication ⊗ over ∧. Hardouin introduce a duality of multiplication ⊗ is dual product which is $\odot$ distribute over ∧. Beside of the dual product in the complete idempotent semiring, it is given dual product in idempotent semiring for two matrices $A\in S^{p\times n}$ and $B\in S^{n\times q}$, is denoted $A\odot X$, is defined as $\left(A\odot X\right)_{ij} = \wedge_{k=1,2,\ldots,n}\left(a_{ik}\odot x_{kj}\right)$ with ∧ represents the greatest lower bound..

After that, about a fixed point equation in a complete lattice also can be applied in the complete idempotent semiring. If is given a complete idempotent semiring S and a mapping $f: S\mapsto S$ so its can be collected a nonempty set $\left\{x\in S \,\middle|\, f\left(x\right)=x\right\}$. Because of order relation in S, its also can be collected a nonempty set $\left\{x\in S \,\middle|\, f\left(x\right)\le x\right\}$ and $\left\{x\in S \,\middle|\, f\left(x\right)\ge x\right\}$. In case of matrix, also can be collected $\left\{X\in S^{n\times m} \,\middle|\, f\left(X\right)=X\right\}$, $\left\{X\in S^{n\times m} \,\middle|\, f\left(X\right)\le X\right\}$ and $\left\{X\in S^{n\times m} \,\middle|\, f\left(X\right)\ge X\right\}$ with f a isotone mapping. The research before, had be researched about the solution of inequality $A \otimes X \leq B$, is defined the isotone mapping $L_A : X \to A \otimes X$, so that the property of the isotone mapping L_A , can be collected a nonempty set $\left\{ X \in S^{n \times m} \left| L_A \left(X \right) = X \right. \right\}$ and $\left\{ X \in S^{n \times m} \left| L_A \left(X \right) \leq X \right. \right\}$.

The research is continued about how to find the least solution of an inequality $A \odot X \geq B$, with is defined a isoton mapping $\wedge_A : X \mapsto A \odot X$, so that the property of the isoton mapping $\wedge_A$ can be collected a nonempty set $\left\{ X \in S^{n \times m} \left| \wedge_A \left(X \right) = X \right. \right\}$ and $\left\{ X \in S^{n \times m} \left| \wedge_A \left(X \right) \geq X \right. \right\}$. With the guarantee of the matrix X which hold $L_A \left(X \right) \leq X$ and $\wedge_A \left(X \right) \geq X$ and also the property $X \geq A \otimes X \Leftrightarrow X \leq A \setminus X \Leftrightarrow X = A^* \otimes X \Leftrightarrow$ $X = A^* \setminus X$ dan $X \leq B \odot X \Leftrightarrow X \geq B \bullet X \Leftrightarrow X = B_* \odot X \Leftrightarrow X = B_* \bullet X$, so that can research how the characteristic of the solution X which hold a inequality $A \otimes X \leq X \leq B \odot X$.

II. RESEARCH METHOD

In the research, a researcher has use some step to find a goal. First, its is studied about semiring theory, especially about a definition and a property of complete idempotent semiring. After that, is be researched that there is the relationship between the complete idempotent semiring and complete lattice. Because of the relationship between them, has be understood residuation theory which hold in complete lattice, especially a lower semicontinous mapping and a upper semicontinous mapping, the definition and the property of residual mapping and dual residual mapping. Because of the same structure between complete idempotent semiring and complete lattice, the definition of the lower semicontinous mapping and the definition of the upper semicontinous mapping also hold in the complete idempotent semiring. Beside that, the property of the residuated mapping and the property of the dual residuated mapping also hold in the complete idempotent semiring. So that, residuation theory can be applied for find the greatest solution of the inequality $A \otimes X \leq B$ and the least solution of the inequality $A \odot X \geq B$ with matrices A, X, B over complete idempotent semiring.

After that, is defined closure mapping and its characteristics is used for find the least solution of the inequality $A \odot X \geq B$. The research is be continued to find the greatest solution of the inequality $A \otimes X \leq B$ with residuation theory. First, is researched the greatest of the inequality $A \otimes X \leq B$ with matrices $A \in S^{n \times n}$, $X \in S^{n \times 1}$. The research is be continued the greatest solution of the inequality $A \otimes X \leq B$ with matrices $A \in S^{n \times n}$, $X \in S^{n \times n}$ and the solution of the inequality $A \otimes X \leq B$ with matrices $A \in S^{n \times p}$, $X \in S^{p \times m}$.

Multiplication is endowed in idempotent semiring, distribute over $\wedge$, so is defined new operation is called dual product in idempotent semiring and dual product in matrix over idempotent semiring. The research is continued about the least solution of the inequality $A \odot X \geq B$, with defined dual residuated mapping

III. MATHEMATICAL BACKGROUND

III.1. RESIDUATION THEORY

Residution has propose for solving unique an equation $f(x) = b$ with inverting isotone mapping f from a complete idempotent semiring D in to another complete idempotent semiring E .

1. f not surjective $\Rightarrow$ $f(x) = b$ will have no solution for some value b .
2. f not injective $\Rightarrow$ $f(x) = b$ will have nonunique subsolution for some value b .

The solution $f(x) = b$ is to consider the subset subsolutions $f(x) = b$, that is value of x satisfying $f(x) \leq b$. These following step are used for solving subsolutions $f(x) = b$:

1. This subset of subsolution is nonempty.
2. Choose the upper bounds of the subset.
3. If the upper bounds of the subset exists, it remains to be checked whether the upper bound itself is the subsolution $f(x) = b$. The other words, the subset of subsolutions $f(x) = b$ has a maximum element , is denoted $f^{\#}(b)$, so we can get

$$f^{\#}(b) = \oplus_{\{x|f(x)\le b\}} x \text{ and } f(f^{\#}(b)) \le b$$

4. After we got the maximum element of the subset of subsolutions, we have could be checked whether its maximum element, in this case $f^{\#}(b)$ satisfying an equation $f(x)=b$. If yes, $f^{\#}(b)$ is the solution of the equation $f(x)=b$.

Beside to get the solution $f(x)=b$, for solving $f(x)=b$ can also get supersolutions $f(x)=b$, that is value of x satisfying $f(x)\ge b$. These following step are used for solving supersolutions $f(x)=b$:

1. This subset of supersolution is nonempty, so can be choosed the lower bounds of the subset of supersolutios $f(x)=b$.
2. If the lower bounds of the subset exists, it remains to be checked whether the lower bound itself is the supersolution $f(x)=b$. The other words, the subset of supersolutions $f(x)=b$ has a minimum element , is denoted $f^{b}(b)$, so we can get
$$f^{b}(b) = \oplus_{\{x|f(x)\ge b\}} x \text{ and } f(f^{b}(b)) \ge b$$
3. After we got the minimum element of the subset of supersolutions, we have could be checked whether its minimum element, in this case $f^{b}(b)$ satisfying an equation $f(x)=b$.
4. If yes, $f^{b}(b)$ is the solution of the equation $f(x)=b$.

Definition 3.1. *Let order set D and E with ordered sets $\le$. An isotone mapping f:D → E is said to be* ***residuated*** *if for all y ∈ E, the least upper bound of subset $\{x\in D | f(x)\le y\}$ is exist and is an element of that subset (that maximum element is exist), that maximum element is denoted $f^{\#}(y)$. All of the element x which hold the equality are called subsolutons of the equality f(x) = y.*

Definition 3.2. *Let order set D and E with ordered sets $\le$. An isotone mapping g:D → E is said to be* ***dually residuated*** *if for all y ∈ E, the greatest lower bound of subset $\{x\in D | g(x)\ge y\}$ is exist and is an element of that subset (that minimum element is exist), that minimum element is denoted $f^{b}(y)$. All of the element x which hold the equality are called supersolutons of the equality g(x) = y.*

Theorem 3.3. *If let f be an isotone mapping $f: E\to F$ with E, F are complete idempotent semirings, a bottom element of E is denoted ε_E, a top element of E is denoted T_E, the following statements are equivalent :*

1. *A mapping f is residuated.*
2. $f(\varepsilon_E)=\varepsilon_F$ *and* $f(\oplus_{x\in X} x) = \oplus_{x\in X} f(x)$ *for all* $X\subseteq E$ *(that f is lower – semicontinuous).*
3. $f(\mathrm{T}_E)=\mathrm{T}_F$ *and* $f^{\#}(\wedge_{y\in Y} y) = \wedge_{y\in Y} f^{\#}(y)$ *for all* $Y\subseteq F$ *(that* $f^{\#}$ *is upper – semicontinuous).*

Theorem 3.4. *If let g be an isotone mapping $g: E\to F$ with E, F are complete idempotent semirings, a bottom element of F is denoted ε_F, a top element of F is denoted T_F, the following statements are equivalent :*

1. *A mapping g is dually residuated.*
2. $g(\mathrm{T}_E)=\mathrm{T}_F$ *and* $g(\wedge_{x\in X} x) = \wedge_{x\in X} g(x)$ *for all* $X\subseteq E$ *(that g is upper – semicontinuous).*
3. $g(\varepsilon_E)=\varepsilon_F$ *and* $g^{b}(\oplus_{y\in Y} y) = \oplus_{y\in Y} g^{b}(y)$ *for all* $Y\subseteq F$ *(that* g^{b} *is lower – semicontinuous).*

III.2. CLOSURE MAPPING

This section, will be explain a closure mapping and that relationship with a residuated mapping and a dually residuated mapping

Definition 3.5. *Let an idempotent semiring S and an isotone mapping* $h: S \mapsto S$ *. If* $h \circ h = h \geq Id_S$ *h is a closure mapping. If* $h \circ h = h \leq Id_S$ *, h is a dual closure.mapping.*

Theorem 3.6 *Let semiring S. If a mapping* $h: S \mapsto S$ *is a residuated mapping, then the following statements are equivalent :*

.11

1. *h is a closure mapping*
2. $h^{\#}$ *is a dual closure mapping*
3. $h \circ h^{\#} = h^{\#}$
4. $h^{\#} \circ h = h$

IV. THE GREATEST SOLUTION OF AN INEQUALITY $A \otimes X \leq B$ WITH MATRIX A ∈ $S^{N \times P}$ AND B ∈ $S^{N \times M}$

For solving an inequality $A \otimes X \leq B$ with A ∈ $S^{n \times p}$ dan B ∈ $S^{n \times m}$ for using residuation theory. In this case for getting the solution of the inequality $A \otimes X \leq B$ with A ∈ $S^{n \times p}$ and B ∈ $S^{n \times m}$, that is

Given a complete semiring idempotent S, matrix A ∈ $S^{n \times p}$ dan B ∈ $S^{n \times m}$. Defined a mapping L_A $S^{n \times p} \to S^{n \times m}$, that is

$$L_A : X \mapsto A \otimes X \qquad (1)$$

Generally, the solution of the inequality $A \otimes X \leq B$ for A ∈ $S^{n \times p}$, X ∈ $S^{p \times m}$ and B ∈ $S^{n \times m}$ are $\left[L_A^{\#}(B)\right]_{ik} = \wedge_{j=1}^{n}\left(A_{ji} \setminus b_{jk}\right) = \left[A \setminus B\right]_{ik}$

Because of all B ∈ $S^{n \times m}$, there is exist a maximal element $L_A^{\#}(B)$ yang $A \otimes X \leq B$ then can be create a isotone mapping $L_A^{\#}$: $S^{n \times m} \to S^{p \times m}$. Furthetmore, a mapping $L_A^{\#}$ is defined for all X ∈ $S^{n \times m}$

$$L_A^{\#} : S^{n \times m} \to S^{p \times m}$$

$$X \mapsto A \setminus X$$

With $\left[A \setminus X\right]_{ik} = \wedge_{j=1}^{n}\left(A_{ji} \setminus x_{jk}\right)$ is called a residuated mapping L_A with A ∈ $S^{n \times p}$.

V. THE LEAST SOLUTION OF AN INEQUALITY $A \odot X \geq B$ WITH MATRIX A ∈ $S^{N \times P}$ AND B ∈ $S^{N \times M}$

V.1 Dual Product

Distributive multiplication ⊙ over ∧ isn't satisfied in a idempotent semiring, generally, is added necessary condition that the idempotent semiring is semifield. That is motivated definition ⊙ is called dual product.

Definition 5.1. *Let a complete idempotent semiring S. Dual product in S is denoted* ⊙ *is biner operation which is assumed have the following characteristics :*

1. *Operation* ⊙ *is assosiative.*
2. *(S,* ⊙ *) has a netral element e.*
3. *Operation* ⊙ *is distributive over* ∧ *for infinite element, that is u* $\forall a_i \in S, \left(\wedge_{i \in I} a_i\right) \odot b = \wedge_{i \in I}\left(a_i \odot b\right)$
4. *Ttop element* T *is as absorb element over* ⊙ *, that is* $\left(\forall a \in S, \mathrm{T} \odot a = a \odot \mathrm{T} = \mathrm{T}\right)$

Then, will let dual product definition for matrix :

Definition 5.2. *Let a complete idempotent semiring S. Matrix A* ∈ $S^{n \times p}$*,B* ∈ $S^{p \times m}$*, then* $A \odot B$ *is defined:*

$$\left(A \odot B\right)_{ij} = \wedge_{k=1,2,\ldots,p}\left(a_{ik} \odot b_{kj}\right)$$

For all $i = 1, 2, \ldots, n$ *and* $j = 1, 2, \ldots, m$.

V.2. The Least Solution of An Inequality $A \odot X \geq B$ **with A ∈ $S^{n \times p}$ and B ∈ $S^{n \times m}$**

Theorem 5.3. *Let a complete idempotent semiring S and matrix* $A \in S^{n \times p}$. *A mapping*

$$\wedge_A : S^{p \times m} \mapsto S^{n \times m}$$
$$X \mapsto A \odot X$$

Is a dually residuated mapping and that dual residual can be denoted

$$\wedge_A^b : S^{n \times m} \mapsto S^{p \times m}$$
$$X \mapsto A \bullet X$$

With the definition operation is

$$[A \bullet X]_{ij} = \oplus_{k=1}^{n} \left(A_{ki} \bullet x_{kj} \right) \qquad (2)$$

$\mathrm{T} \bullet x = \varepsilon, \varepsilon \bullet x = \mathrm{T}$, and $\varepsilon \bullet \varepsilon = \varepsilon$

VI. THE SOLUTION OF INEQUALITY $A \otimes X \leq X \leq B \odot X$

VI. 1 Fixed Point Equations and Inequality of Fixed Point.

Definiton 6.1. *Let a set A and function* $f : A \to A$. *An element* $a \in A$ *is called a* ***fixed point*** *of function* f *if* $f(a) = a$. *Furthermore,* a *can be called a solution of the fixed point equation* $x = f(x)$. *When the set* A *is endowed with a ordered relation* $\leq$, *can be defined* ***prefixed point*** *of* f , *that is* $a \in A$ *is called* ***prefixed points*** *of* f *if* $f(a) \leq a$. *Besides that, can also be defined a post-fixed point of* f , *that is* $a \in A$ *is called* ***post-fixed points*** *of* f *if* $f(a) \geq a$.

Because the complete idempotent semiring S is the ordered set with the ordered relation $\leq$ then it can be defined a fixed point equation of a isoton mapping $f : S \to S$, that is :

$$f(x) = x \qquad (3)$$

and fixed point inequality $f : S \to S$ has the following hold:

$$f(x) \leq x \qquad (4)$$
$$f(x) \geq x \qquad (5)$$

VI.2 Kleene Star

Definition 6.2. *Let a complete idempotent semirings S. Kleene star is a mapping.*

$$k : S \mapsto S, a \mapsto a* = \oplus_{i=0}^{\infty} a^i$$

With $a^{i+1} = a \otimes a^i$ *and* $a^0 = e$.

Kleene star can also be applied to a square matrix in the complete idempotent semiring.

Definition 6.3. *Let a complete idempotent semiring S. Kleene Star of matrix* $A \in S^{n \times n}$ *is defined by*

$$K : S^{n \times n} \mapsto S^{n \times n}, A \mapsto A* = \oplus_{i=0}^{\infty} A^i$$

with $A^0 = E$, *E an identity matrix and*

$$A^k = A \otimes A^{k-1}.$$

Propotition 6.4. *Let a complete idempotent semiring S. Matrix* $A \in S^{n \times n}$ *and* $X \in S^{n \times p}$. *A mapping* L_{A^*} : $S^{n \times p} \to S^{n \times p}$, $X \mapsto A^* \otimes X$ *is a closure mapping, so that is,*

$$A^* \otimes A^* \otimes X = A^* \otimes X$$

As a consequence,

$$X = A^* \otimes X \Leftrightarrow X \in \operatorname{Im} L_{A^*} \qquad (3)$$

Lemma 6.5. *Given a complete idempotent semiring S, matrices A* $\in S^{n\times n}$ *and X* $\in S^{n\times p}$
The following equivalences hold:

1. $X \le A \setminus X$
2. $X \ge A \otimes X$
3. $X = A^* \otimes X$
4. $X = A^* \setminus X$

VI.3. Dual Kleene Star

Definition Kleene star explain that Kleene Star is the sum of infinite ⊕ of an element in a complete idempotent semiring. The following duality of Kleene Star i.e. dual Kleene Star which is meet ∧ infinite. of an element in a complete idempotent semiring.

Definition 6.6. *Given a complete idempotent semiring S. Dual Kleene Star is a mapping*

$$l : S \mapsto S, b \mapsto b_* = \wedge_{i=0}^{\infty} b^{\odot i}$$

where $b^{\odot i+1} = b \odot b^{\odot i}$ *and* $b^{\odot 0} = e$

Selanjutnya, pendefinisian dual star dapat pula diaplikasikan dalam kasus ma-trik, sebagaimana dijelaskan mengenai dual star pada matrik.

Definisi 6.7. *Given a complete idempotent semiring S. Dual Kleene Star for matrix B* $\in S^{n\times n}$ *is defined by*

$$B_* = \wedge_{k=0}^{\infty} B^{\odot^k}$$

Where $B^{\odot i+1} = B \odot B^{\odot i}$ *and* $B^{\odot 0} = E$

Sifat 6.8. *Given matrix* $B \in S^{n\times n}$. *A mapping* $\wedge_{B_*}$ *is upper semicontinuous mapping and according to Defintioni 5.6., a mapping* $\wedge_{B_*} : S^{n\times p} \mapsto S^{n\times p}$, $X \mapsto B_* \odot X$ *is a dual closure mapping. So that,*

$$B_* \odot B_* \odot X = B_* \odot X \qquad (4)$$

As consequence is

$$X = B_* \odot X \Leftrightarrow X \in \mathrm{Im} \wedge_{B_*} \qquad (5)$$

Propotition 6.9. *Given a complete idempotent semiring S, matrices B* $\in S^{n\times n}$ *and X* $\in S^{n\times p}$*, then the following equivalences hold :*

1. $X \le B \odot X$
2. $X \ge B \bullet X$
3. $X = B_* \bullet X$
4. $X = B_* \odot X$

Proposisi 6.10. *Given a complete idempotent semiring S, matrices A, B* $\in S^{n\times n}$ *and X* $\in S^{n\times m}$. *The following equivalences hold :*

$$A \otimes X \le X \le B \odot X \Leftrightarrow X \in \mathrm{Im} L_{A^*} \cap \mathrm{Im} \wedge_{B_*}$$

Proposisi 6.11. *Given a complete idempotent semiring S, and matrices A, B, G* $\in S^{n\times n}$. *The greatest of solution is X which is hold :*

$$A \otimes X \le X \le B \odot X \text{ dan } X \le G$$

is

$$X = \left(\left(B_* \bullet A^*\right)^*\right) \setminus G$$

Proof :

1. Proved that $A \otimes X \le X \le B \odot X$ dan $X \le G \Rightarrow X \le \hat{X}$. According to Propotition 6.10, $A \otimes X \le X \le B \odot X \Leftrightarrow X \in \mathrm{Im} L_{A^*} \cap \mathrm{Im} \wedge_{B_*}$. That mean matrix X must hold $X = B_* \bullet (A^* \otimes X)$.

$$X = B_* \bullet (A^* \otimes X)$$
$$\Leftrightarrow X = (B_* \bullet A^*) \otimes X)$$
$$\Leftrightarrow X = ((B_* \bullet A^*)^*) \setminus X$$

Therefore, $A \otimes X \le X \le B \odot X$ and $X \le G \Rightarrow X = ((B_* \bullet A^*)^*) \setminus X$ and $X \le G$. Attention that Theorem 6.5, $X = ((B_* \bullet A^*)^*) \setminus X \Leftrightarrow (B_* \bullet A^*) \otimes X \le X$. Bacause of $(B_* \bullet A^*) \otimes X \le X$ and $X \le G$ then $X \le \hat{X} = ((B_* \bullet A^*)^*) \setminus G$.

2. Proved that $\hat{X} \le G, \hat{X} = A^* \otimes \hat{X}$.

First, will proved that $\hat{X} \in \operatorname{Im} L_{A^*}$ is equivalent $\hat{X} = A^* \otimes \hat{X} = A^* \setminus \hat{X}$. According to Lemma 6.5, $\hat{X}$ hold by

$$(B_* \bullet A^*) \otimes \hat{X} \le \hat{X} \le (B_* \bullet A^*) \setminus \hat{X} \qquad (9)$$

Because of an isotone mapping L_{A^*} and $\hat{X} \le (B_* \bullet A^*) \setminus \hat{X}$, then $A^* \otimes \hat{X} \le A^* \otimes ((B_* \bullet A^*) \setminus \hat{X})$. Therefore,

$$A^* \setminus \hat{X} \ge A^* \setminus ((B_* \bullet A^*) \setminus \hat{X})$$

Attention that

$$A^* \setminus ((B_* \bullet A^*) \setminus \hat{X}) = ((B_* \bullet A^*) \otimes A^*) \setminus \hat{X}$$
$$= (B_* \bullet (A^* \otimes A^*)) \setminus \hat{X}$$
$$= (B_* \bullet A^*) \setminus \hat{X}$$

So that, be got $A^* \setminus \hat{X} \ge (B_* \bullet A^*) \setminus \hat{X}$. According to inequality 9, $(B_* \bullet A^*) \setminus \hat{X} \ge \hat{X}$. Consequently, get inequality $A^* \setminus \hat{X} \ge (B_* \bullet A^*) \setminus \hat{X} \ge \hat{X}$. Thus $A^* \setminus \hat{X} \ge \hat{X}$. After that, $\hat{X} \ge A^* \setminus \hat{X}$ (because of $A^* \ge E$) then $A^* \setminus \hat{X} = \hat{X}$, i.e. $\hat{X} \in \operatorname{Im} L_{A^*}$.

The second, proved $\hat{X} \in \operatorname{Im} \wedge_{B_*}$, i.e. $\hat{X} = B_* \odot \hat{X} = B_* \bullet \hat{X}$. From the equation 9. Be got $\hat{X} \ge (B_* \bullet A^*) \otimes \hat{X} = B_* \bullet (A^* \otimes \hat{X}) = B_* \bullet \hat{X}$ (because of $\hat{X} = A^* \otimes \hat{X}$). The other side, $B_* \le E^{\odot}$. Because of $\wedge_{B_*}$ an isotone mapping, then $B_* \odot \hat{X} \le E^{\odot} \odot \hat{X}$. Consequently, can be got $\hat{X} \le B_* \bullet \hat{X}$. So that, $\hat{X} = B_* \bullet \hat{X} = B_* \odot \hat{X}$.

Third, because of inequality $(B_* \bullet A^*)^* \ge E$, then $(B_* \bullet A^*)^* \odot G \ge E \odot G$. Consequently, can be got $(B_* \bullet A^*)^* \setminus G \le G$. So that, be got $\hat{X} \le G$.

VII. KESIMPULAN DAN SARAN

VII.1 Conclusion

In this paper, can be concluded that the same structure beetwen a complete idempotent semiring and a complete lattice give more advantages for solving inequality of a complete idempotent semiring by using residuation theory. Given complete idempotent semiring S , then

1. Solution of inequality $A \otimes X \le B$ with matrices $A \in S^{n \times p}$ and $B \in S^{n \times m}$ is $\wedge_{j=1}^{n} (A_{ji} \setminus b_{jk}) = [A \setminus B]_{ik}$.
2. Solution of inequality $A \odot X \ge B$ with matrices $A \in S^{n \times p}$ and $B \in S^{n \times m}$ is $(A \bullet X)_{ij} = \oplus_{k=1}^{n} (A_{ki} \bullet x_{kj})$.
3. Solution of inequality $A \otimes X \le X \le B \odot X$ dan $X \le G$ dengan $A, B, G \in S^{n \times n}$ can be get with formula $\hat{X} = ((B_* \bullet A^*)^*) \setminus G$.

VII.2 Suggestion

1. In case that relation of Propotition 6.10 and Propotition 6.11, is necesarry explanation about the best approximation terbaik an element in G by another element in $\gamma^{b}_{L_{A^*}}$ but that is explained in this paper, yet. So that, can be added for completing the relationship beetwen Proposisi 6.10 and Proposisi 6.11 in this paper.
2. This research can be continued for solving inequality $A \otimes X \leq X \leq B \odot X$ and $X \leq G$, i. e the greatest solution where matrices $A, B, G \in IS^{n\times n}$ with a semiring IS is interval semiring.

***Abstract*—**Traffic jam often occurs while going to somewhere and interfere daily activities. Traffic jam happens because of the movement conflict at the intersection. Traffic is an important thing in controlling the intersection. The use of Welch -Powell algorithm to optimize the traffic light. The purpose of this research is to find out: (1) application of graph coloring on the intersection using the Welch -Powell algorithm to optimize the traffic light settings and, (2) finding out the calculation of waiting time results accord to coloring graph with the arrangements that have been adopted. The research method is including some steps that is data collection, data analysis and processing, manufacturing simulation, and conclusion. The data that used in this paper is primary data. Retrieval of data held in Matraman intersection, East Jakarta. The data is taken by the duration of the red light, yellow, and green when its turn on each the intersection .The obtained data then analyzed by several steps, that is (1) transforming the intersection into the form of graphs; (2) Coloring graph using Welch -Powell algorithm; and (3) calculating the duration of the settlement alternative traffic light and then calculate the level of effectiveness, subsequent manufacture of simulation. From this analyze we know that the results of the calculation is for the intersection. By this application, hope that can handle of the problem at the intersections traffic light and reduce traffic jam.

Keywords: *coloring graph, traffic light, welch-powell algorithm..*

I. INTRODUCTION

The operation of standard traffic lights which are currently deployed in many junctions, are based on predetermined timing schemes, which are fixed during the installation, and remain until further resetting. The timing is no more than a default setup to control what may be considered as normal traffic. Although every road junction by necessity requires different traffic light timing setup, many existing systems operate with an over simplified sequence. This has instigated various ideas and scenarios to solve the traffic problem.

Problem solving traffic light can be reviewed in the perspective of the graph, namely by representing the junction in the form of a graph. Vertex graph shows the direction of travel is allowed on the road X towards the Y, meanwhile the edge graph indicates the direction of travel that should not be done simultaneously. Subsequently finish with vertex coloring method using Welch - Powell algorithm.

This settlement will generate currents that can run simultaneously, but it also gained new alternative cycle duration. This new cycle duration will be compared with the cycle time of secondary data from the traffic light Matraman and is expected to be a solution for road users in order to speed up the waiting period when the red light is on.

II. BASED THEORY

A. Graph

An undirected graph G is given by an ordered pair G= (V, E), where V is a set of vertices, |V|= n, and $E \subset V\ x\ V$- a set of edges, |E|= m. Two Vertices u, v ∈ V are called adjacent if they are connected by an edge: {u, v} ∈ E. An edge and a vertex on this edges incident. The degree deg (v) of a vertex v is measured as the number of edge incident to the vertex v: deg (v) = | {e∈: v ∈e}|.

B. Vertex Coloring

Let G be a graph without loops. A k-coloring of G is an assignment of k colors to the vertices of G in such a way that adjacent vertices are assigned different colors. If G has a k-coloring, then G is said to be k-colorable. The chromatic number of G, denoted by$\chi(G)$, is the smallest k for which G is k-colorable.

The color on a vertices can be represented by numbers or can also be represented directly using the color for example red, green, blue, yellow and others. The main problem in the coloring of the vertices is the search for solutions which use a minimum number of colors. The minimum number of colors used to color the graph is called the chromatic number

One algorithm that gives a good solution to a vertex-coloring problem is the *Welch•-Powell algorithm*. It may not always give the best solution, but it will usually perform better than just coloring the vertices without a plan will.

The Welch-Powell algorithm consists of the following steps:

1. Find the valence for each vertex.
2. List the vertices in order of descending valence (you can break ties any way you wish).
3. Color the first vertex in the list (the vertex with the highest valence) with color 1.
4. Go down the list and color every vertex not connected to the colored vertices above the same color. Then cross out all colored vertices in the list.
5. Repeat the process on the uncolored vertices with a new color - always working in descending order of valence until all the vertices have been colored.

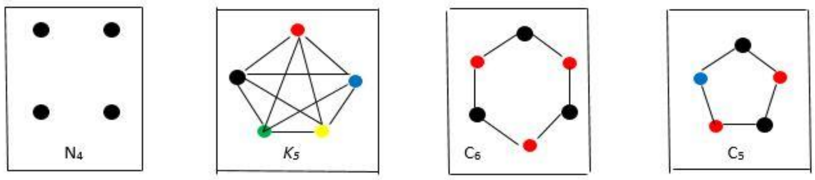

Figure 1. Example Chromatic Number

III. METHOD RESEARCH

To conduct the study must consider the procedures and steps that will be taken to initiate research that can be focused and performing well in terms of research reporting.

A. Method of Collecting Data

Research using several types of data collection methods, among others: the study of literature by collecting journals both national and international, dealing with Welch-Powell algorithm on graph coloring and traffic light settings, as well as field observations.

B. Method of Data Analysis

Qualitative methods used to identify and formulate the design principles Welch - Powell algorithm on graph coloring and setting the current total waiting time at traffic light intersections through qualitative descriptive analysis and content analysis. Literature study method is used to analyze matters concerning the concept of Welch - Powell algorithm on graph coloring and total waiting time at traffic light.

IV. RESULTS

A. Implementation of vertex coloring on traffic light Matraman

Traffic light available at a road intersection has several purposes, such as avoid obstacles because of differences in the flow path for the movement of vehicles, in order to facilitate pedestrians can cross safely, and reduce the rate of accidents caused by collisions due to differences in the flow path. But traffic light also has some problems that need to be resolved, one of the setting from duration of the red and green lights. This problem can be studied using the principle of vertex coloring settings.

For more details, here are the steps vertex coloring app on the traffic light at the intersection:

1. Transforming the crossroads along the current into the form of graphs. The vertex represents the current and the edge represents uncompatible currents, meaning that currents that should not be run simultaneously, which further vertices are interconnected.
2. Coloring each vertex in a graph using the Welch - Powell algorithm. In addition to knowing where the currents that could run concurrently, obtained also the amount of chromatic number that will be useful at a later stage.
3. Specifies an alternative to the settlement duration of green lights and red lights with a certain time cycle, how to divide one cycle consisting of a total duration of red and green light with chromatic number has been obtained from step 2 , the result of the division indicates the duration of the green light .

The following will describe one of case settlement arrangement that traffic light of Matraman intersection. Here is an illustration of the road at the intersection Matraman.

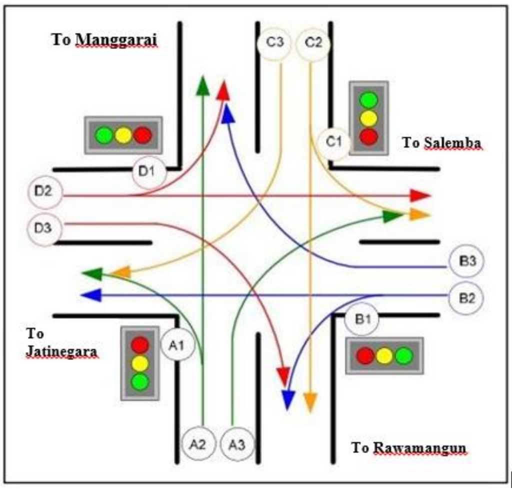

Figure 2. Illustration of Matraman traffic light

From the illustration Figure 2 by referring to the steps that have been described previously obtained results graph transformation as follows:

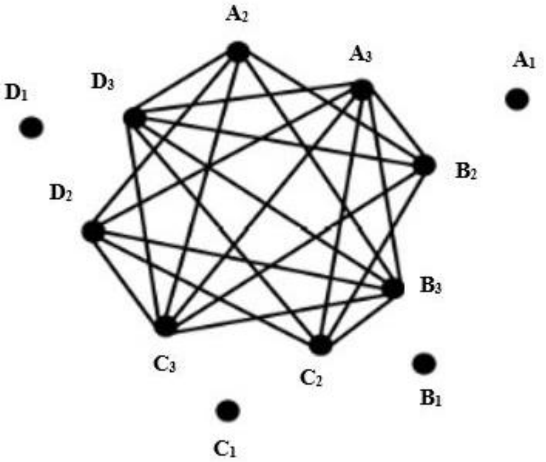

Figure 3. Graph of Matraman Traffic Light

From transformation of graph above, we know that the vertex A_1, B_1, C_1, D_1 are vertex foreign, it's mean that A_1, B_1, C_1, D_1 can simultaneously with other currents. So for the current stated by A_1, B_1, C_1, D_1

always apply the green light. Then, to the remaining vertex will be colored with Welch-Powell algorithm. Vertex coloring produced can be seen in Figure 4 below:

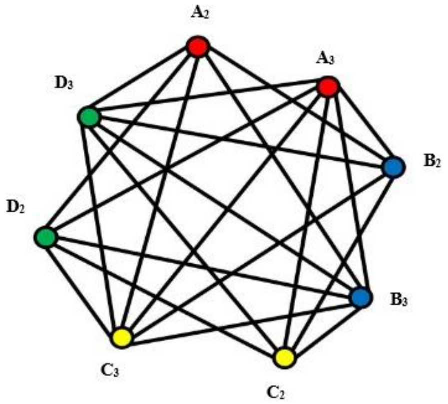

Figure 4. Result of Coloring Graph at Matraman Traffic Light

Obtained by the above coloring graph of chromatic number is 4 and the currents can be together as bellows:

Table 1. Vertex Colors Graph Matraman Traffic Light

Colors	Vertex
Red	A_2, A_3
Blue	B_2, B_3
Yellow	C_2, C_3
Green	D_2, D_3

From Table 1, can be formed partition of settings traffic light as bellows: 1) First partition, the current A_2 goes along with the current $A_{3,}$ 2) Second partition, the current B_2 goes along with the current B_3, 3) Third partition, the current C_2 goes along with the current C_3, 4) Fourth partition, the current D_2 goes along with the current $D_{3.}$

Table 2. Primary Data of Matraman Traffic Light

Intersections	Red	Yellow	Green	Total
Rawamangun	420	2	15	**437**
Jatinegara	244	2	85	**331**
Manggarai	320	2	42	**364**
Salemba	162	2	195	**359**
Total	**1146**	**8**	**337**	**1491**

Based on primary data obtained has found that intersection Matraman cycle time and the amount of chromatic number is 4. For alternative settlement of traffic lights can be seen below.

Table 3. Alternative settlement duration of traffic lights

Intersections	Traffic Light	Calculation	Results (second)
Rawamangun	Green Yellow Red	437/4 437-109.25-2	109.25 2 325.75
Jatinegara	Green Yellow Red	331/4 331-82.75-2	82.75 2 246.25
Manggarai	Green Yellow Red	364/4 364-91-2	91 2 268

Salemba	Green Yellow Red	359/4 359-89.75-2	89.75 2 267.25

from the above data, found that the results of new data as follows:

Table 4. New Data of Matraman Traffic Light

Intersections	**Red**	**Yellow**	**Green**
Rawamangun	325.75	2	109.25
Jatinegara	246.25	2	82.75
Manggarai	268	2	91
Salemba	267.25	2	89.75
Total	**1107.25**	**8**	**372.75**

Based on the duration of the red light and green light on traffic light Matraman. it can be seen that the new data the result of resolving cases Matraman traffic light settings by using welch-powell algorithm more effective than primary data. The following table is presented primary data and new data Matraman traffic light.

Table 4. Primary Data and New Data of Matraman Traffic Light

	Primary Data			**New Data**		
Intersections	**Red**	**Yellow**	**Green**	**Red**	**Yellow**	**Green**
Rawamangun	420	2	15	325.75	2	109.25
Jatinegara	244	2	85	246.25	2	82.75
Manggarai	320	2	42	268	2	91
Salemba	162	2	195	267.25	2	89.75
Total	**1146**	**8**	**337**	**1107.25**	**8**	**372.75**

The total duration of the green light from the primary data is 337 seconds, while the total duration of the vertex coloring green light was 372.75 seconds. The level of effectiveness that is

$$\frac{375.75 - 337}{337} x100\% = 11.49\%$$

The total duration of the red light from the primary data is 1146 seconds, while the total duration of the vertex coloring red light was 1107.25 seconds. The level of effectiveness that is

$$\frac{1146 - 1107.25}{1107.25} x100\% = 3.49\%$$

So for the case Matraman traffic light, green light duration will increase by 11.49% while the duration of the red light can be reduced by 3.49%

CONCLUSION

Based on the analysis and discussion can be drawn the conclusion that implementation of the intersection graph Welch - Powell algorithm for optimization of traffic light settings is by means (1) Transforming intersection along the current path to the form of graphs, (2) Coloring each vertex in the graph with Welch - Powell algorithm, (3) Determine the duration of the settlement alternative green light and red light, (4) Calculating the total duration of effectiveness level traffic light.

The Normality of Subgroups of n x n Matrices Over Integers Modulo Prime

Ibnu Hadi[1]
[1] Mathematics Department, Jakarta State University, Indonesia
ibnu_unj@yahoo.co.id, ibnu_hadi@unj.ac.id,

Abstract**—**This paper discusses about some properties of noncommutative finite group consists of n x n nonsingular matrices over integers modulo prime under matrix multiplication. Here we want to determined the normality of subgroups. Using Lagrange theorem, the subgroups of this noncommutative finite group is exist. We considered trivial and some nontrivial subgroups. The nontrivial subgroups which is considered here is matrices set with determinant one, upper triangular matrices and center of group. Start from 2 x 2 matrices, the set with only consist of identity element is normal subgroups. It can be happen because the noncommutative properties plays here. For 3 x 3 matrices, nontrivial subgroup is possible to be normal. In general, for group consist of n x n nonsingular matrices over integers modulo prime, not all of the subgroups is normal. Generally, subgroup consist only identity element of group is normal.

Keywords: *integers modulo prime, normality, subgroup*.

I. INTRODUCTION

On the previous paper, [7] got the order of group consists of n x n matrices over integers modulo prime numbers. In that paper, he give some open problems which is unsolved. On the other hand, as special case, [6] has discussed the normality of some subgroup from group of all nonsingular 3 x 3 matrices over integers modulo prime. Now, in this paper, by general order of matrices n x n and any prime number, we want to know the normality of some subgroups in noncommutative finite group. This is important because we work under one example of noncommutative groups. Usually, by commutative property of commutative group, we can easy to check the normality of the subgroup. But it can be different when the commutative property of group is dropped. Our motivation is to ensure that in noncommutative group it is possible to define normal subgroup. Hopefully, after the normality of subgroup is defined, we can extend the problem for this group using another concept in group theory such the quotient group, ring and etc.

In this paper, we start solving the normality from simple case for 2 x 2 matrices over integers modulo prime and continues to general form of n x n matrices. This is a good step to emphasize the existences of normal subgroup in general. By considered some subgroup of 2 x 2, we will get the pattern to define normal subgroup. After that, we expand for 3 x 3 matrices and n x n matrices. Note that the subgroup only considered for the set of matrices with determinant one, upper triangular matrice, and center of group. It is possible to check for any subgroup because in group, many various way to define th subgroup. We choose these subgroup because it is more simple than any other subgroup.

II. DISCUSSION

Let $Gl_{\mathrm{n}}\left(Z_p\right)=\left\{\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix} \middle| a_{11},\ldots,a_{nn}\in Z_p, \det\left(\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}\right)\neq 0\right\}$ is a set of n x n nonsingular matrices over integers modulo prime p. Under matrix multiplication this set form a group. For $n=2$ and $p=2$, we get

$$Gl_2(Z_2)=\left\{\begin{bmatrix} a & b \\ c & d\end{bmatrix}\middle| a,b,c,d\in Z_2, ad-bc\neq 0\right\}$$
$$=\left\{\begin{bmatrix} 1 & 0 \\ 0 & 1\end{bmatrix},\begin{bmatrix} 0 & 1 \\ 1 & 0\end{bmatrix},\begin{bmatrix} 1 & 0 \\ 1 & 1\end{bmatrix},\begin{bmatrix} 1 & 1 \\ 1 & 0\end{bmatrix},\begin{bmatrix} 1 & 1 \\ 0 & 1\end{bmatrix},\begin{bmatrix} 0 & 1 \\ 1 & 1\end{bmatrix}\right\}$$

is a noncommutative finite group under matrix multiplication where order $Gl_2(Z_2)$ is 6 ($o(Gl_2(Z_2))=6$) . Let $A=\begin{bmatrix} 1 & 0 \\ 0 & 1\end{bmatrix}$, $B=\begin{bmatrix} 0 & 1 \\ 1 & 0\end{bmatrix}$, $C=\begin{bmatrix} 1 & 0 \\ 1 & 1\end{bmatrix}$, $D=\begin{bmatrix} 1 & 1 \\ 1 & 0\end{bmatrix}$, $E=\begin{bmatrix} 1 & 1 \\ 0 & 1\end{bmatrix}$, $F=\begin{bmatrix} 0 & 1 \\ 1 & 1\end{bmatrix}$ where A is identity element, then we have tabel operation below

Table 1. Matrix operation under $Gl_2(Z_2)$

*	**A**	**B**	**C**	**D**	**E**	**F**
A	A	B	C	D	E	F
B	B	A	D	C	F	E
C	C	F	A	E	D	B
D	D	E	B	F	C	A
E	E	D	F	B	A	C
F	F	C	E	A	B	D

Now, let see the definition from [8]

Definition. If H is a subgroup of G, $a\in G$, then $Ha=\{ha \mid h\in H\}$ and $aH=\{ah \mid h\in H\}$. Ha and aH are called right coset and left coset, respectively, of H in G.

It is clear that $H_A=\{A\}$ and $H_{Gl_2(Z_2)}=Gl_2(Z_2)$ are trivial subgroups of $Gl_2(Z_2)$ which have $o(H_A)=1$ and $o\left(H_{Gl_2(Z_2)}\right)=o(Gl_2(Z_2))=6$, then $H_Aa=aH_A$ for all $a\in Gl_2(Z_2)$. But, there exist $B,C\in H_{Gl_2(Z_2)}=G$ such that $BC=D\in H_{Gl_2(Z_2)}a$ and $CB=F\in aH_{Gl_2(Z_2)}$ where $BC=D\neq F=CB$. So $H_{Gl_2(Z_2)}a=aH_{Gl_2(Z_2)}$ is not hold in general for $a\in Gl_2(Z_2)$. Before we continue, from [9] let consider Lagrange Theore below.

Lagrange's Theorem. If G is a finite group and H is a subgroup of G, then the order of H divides the order of G.

By this theorem, it is clear that $o(H_A)\Big|_{o(Gl_2(Z_2))}$ and $o\left(H_{Gl_2(Z_2)}\right)\Big|_{o(Gl_2(Z_2))}$. Furthermore, we can find another subgroup H of $Gl_2(Z_2)$ such that $o(H)\Big|_{o(Gl_2(Z_2))}$. In our case, $o(H)$ can be 2 or 3. From the table 1, we can construct $H_1=\{A,B\}$ is a subgroup of $Gl_2(Z_2)$ where $o(H)_1=2$. Now we check $H_1a=aH_1$ for all $a\in Gl_2(Z_2)$. Again, we get in H_1a for $a=C\in Gl_2(Z_2)$ and $B\in H_1$, $H_1a\neq aH_1$. And for subgroups $H_2=\{A,C\}$, $H_3=\{A,E\}$, $H_4=\{A,D,F\}$ it can be shown that $H_2a\neq aH_2$, $H_3a\neq aH_3$, and $H_4a\neq aH_4$ for some $a\in Gl_2(Z_2)$. So far, in $Gl_2(Z_2)$ we only have one subgroup such that right coset is similar with left coset. Furthermore, by definition below we will define normal subgroup in [9].

Definition. $N \lhd G$ (N is normal subgroup in G) if and only if every left coset of N in is a right coset in G.

By this definition, we can conclude that the only normal subgroup in $Gl_2(Z_2)$ is $H_A = \{A\}$. If we classify all of subgroups of $Gl_2(Z_2)$, we can characterize become subgroup with determinant one is $H_A = \{A\}$, upper triangular matrix is $H_3 = \{A, E\}$. For any group G, let define center of group by $Z(G) = \{z \in Gx | zx = xz \text{ for all } x \in G\}$. It is clear for $Z(Gl_2(Z_2)) = \{E\}$. So far, we already check for $n = 2$, $p = 2$, the only normal subgroup is trivial subgroup consist only identity element.

From [5], we get order of $Gl_2(Z_p)$ is $p^4 - \left((2p-1)^2 + (p-1)^3\right)$. The problem is not easy if we want to find some normal subgroup for any prime p in $Gl_2(Z_p)$. Fortunately, by Lagrange's Theorem, at least one of subgroup in $Gl_2(Z_p)$ i.e trivial subgroups consist only identity element. How about group consist of 3 x 3 matrices over integers modulo prime? By [6], we get the order of $Gl_3(Z_p)$, is $(p-1)^3 p^3 (p+1)\left(p^2 + p + 1\right)$. From this, if we define $H = \left\{ \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \middle| a_{ij} \in Z_p, \left| \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \right| = 1 \right\}$, then $H \lhd G$. Moreover, [6] got $Z(Gl_3(Z_p)) = \left\{ z \in Gl_3(Z_p) \middle| zx = xz \text{ for all } x \in Gl_3(Z_p) \right\} \lhd Gl_3(Z_p)$. In addition, if we consider all of diagonal matrices in $Gl_3(Z_p)$, in set notation $D_3(Z_p) = \left\{ \begin{bmatrix} s & 0 & 0 \\ 0 & t & 0 \\ 0 & 0 & u \end{bmatrix} \middle| s, t, u \in Z_p \right\}$ is not normal in $Gl_3(Z_p)$ except if $p = 2$. We can say that $D_3(Z_p)$ is special upper triangular matrices in $Gl_3(Z_p)$. So we can get another normal subgroup which is nontrivial subgroup.

Let get back to $Gl_n(Z_p)$, and define $H_1(Gl_n(Z_p))$ as a set of all nonsingular n x n matrices over Z_p whose determinant is one. It can be easily shown that $H_1(Gl_n(Z_p))$ is subgroup of $Gl_n(Z_p)$. Let $A, B \in H_1(Gl_n(Z_p))$, then $A \equiv B \bmod H_1(Gl_n(Z_p))$ if and only if $\left|AB^{-1}\right| = 1$ if only if $|A| = |B|$. Then, $H_1(Gl_n(Z_p)) \lhd Gl_n(Z_p)$ for if $A \in Gl_n(Z_p)$ and $K \in H_1(Gl_n(Z_p))$ then $\left|AKA^{-1}\right| = 1$ and hence $AKA^{-1} \in H_1(Gl_n(Z_p))$ which shows that $AH_1(Gl_n(Z_p))A^{-1} \subseteq H_1(Gl_n(Z_p))$.

Let define $Gl_{\mathrm{n},u}\left(Z_p\right)=\left\{\left.\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ 0 & a_{22} & \cdots & a_{2n} \\ 0 & 0 & \ddots & \vdots \\ 0 & 0 & \cdots & a_{nn} \end{bmatrix}\right\| a_{11},\ldots,a_{nn}\in Z_p\right\}$ as a set of all upper triangular matrices in $Gl_n\left(Z_p\right)$. Then for $A,B\in Gl_{\mathrm{n},u}\left(Z_p\right)$, $AB\in Gl_{\mathrm{n},u}\left(Z_p\right)$, assosiative properties hold and $I_n\in Gl_{\mathrm{n},u}\left(Z_p\right)$. It is clear that $a_{ii}, i=1,2,\cdots,n$ is all not zero so that every element in $Gl_{n,u}\left(Z_p\right)$ is invertible. So form a subgroup of $Gl_n\left(Z_p\right)$. For all $X\in Gl_n\left(Z_p\right)$, $A\in Gl_{\mathrm{n},u}\left(Z_p\right)$, then $XAX^{-1}\in Gl_{\mathrm{n},u}\left(Z_p\right)$. This is obvious from [1] that the multiplication of any matrix with upper triangular matrix is upper triangular matrix too. But in general, we cannot say $Gl_{n,u}\left(Z_p\right)\lhd Gl_n\left(Z_p\right)$ because there exist $X\in Gl_n\left(Z_p\right)$ and $A\in Gl_{\mathrm{n},u}\left(Z_p\right)$ such that $XGl_{\mathrm{n},u}\left(Z_p\right)\neq Gl_{\mathrm{n},u}\left(Z_p\right)X$. Here noncommutative properties of matrix set plays. On the other hand, if we define $Z\left(Gl_n\left(Z_p\right)\right)=\left\{z\in Gl_n\left(Z_p\right)\middle| zx=xz \text{ for all } \mathrm{x}\in Gl_n\left(Z_p\right)\right\}$, by our concept, center of group is always normal subgroup. Some problem wthat is not solved is how to define order of $H_1\left(Gl_n\left(Z_p\right)\right)$, $Gl_{n,u}\left(Z_p\right)$, and $Z\left(Gl_n\left(Z_p\right)\right)$.

III. Conclusion

Basicly, noncommutative finite group is interesting to learned. The normality of subgroup of group consist of n x n nonsingular matrices over integers modulo prime cannot determine directly. It is depends on the number of integer n and prime number p. The problem rise up when we want to know the order of these subgroups. Our sugestion is determine the order at the first then we check the normality of subgroup. After that it is possible to define any group such that quotient of group.

Abstract— Let G =(V(G),E(G)) be any graph of order n = |V(G)| and measure k = |$E(G)$|, W = { w_1, w_2, ..., w_k} be an order set of vertices and y a vertex in G. The adjacency representation of y with respect to W is the ordered k-tuple $r(y|W) = (d(y, w_1), d(y, w_2), ..., d(y, w_k))$, where $d(u, v)$ represents the adjacency distance between the vertices u and v. The set W is called an adjacency resolving set of G if every two vertices u and v in G satisfy $r(u|W) \neq r(v|W)$. A minimum adjacency resolving set for G is an adjacency metric basis of G. Adjacency metric dimension for G, $\dim_A(G)$, is the cardinality of vertices in an adjacency metric basis for G. In this paper, we study and determine the *adjacency metric dimension* of graphs with pendant points. A pendant point is every vertex of an empty graph, $H=\overline{K_m} \cong mK_1, m \geq 1$ that joining two end-vertices s_i, s_h of edge $e_j = s_is_h$ of G in $G\Diamond H.$ An Edge-corona graph $G\Diamond H$ is a graph formed by taking G and k = |$E(G)$| copies of H then joining two end-vertices s_i, s_h of edge $e_j = s_is_h$ of G to every vertex in the j^{th}-copy of H. So, if we choose an emphty graph, $\overline{K_m} \cong mK_1, m \geq 1$ as H of an edge-corona graph $G\Diamond H,$ we obtain a graph with pendant points.

Keywords: *adjacency distance, adjacency resolving set, adjacency metric dimension, edge-corona graph, pendant point*

I. INTRODUCTION

This section presents about some definitions and known results that are using for prove the main theorem of this research. We begin with, G = (V(G),E(G)) is a simple, finite and connected graph with a set of vertices V(G) and a set of edges E(G), of cardinality n and k, respectively. Two adjacent vertices u and v will be write $u \sim v$ and two vertex u and v that is not adjacent with $u \not\sim v.$ The distance between two vertices u and v in G, $d(u,v)$ is the lenght of shortest path joining u and v. The adjacency distance between u and v denoted by $d_A(u,v)$, and defines by [4], $d_A(u, v_i) = \begin{cases} 0 & if\ u = v_i, \\ 1 & if\ u \sim v_i, \\ 2 & if\ u \not\sim v_i. \end{cases}$ Let $W = \{w_1, w_2, ..., w_k) \subseteq V(G)$ be an order set of vertices and y a vertex in G. The adjacency representation of y with respect to W is the ordered k-tuple $r_A(y|W) = (d_A(y, w_1), d_A(y, w_2), ..., d_A(y, w_k))$. W is called adjacency resolving set of G, if a pair of distinct vertices in G have different adjacency representation.. A minimum adjacency resolving set for G is an adjacency metric basis of G. Adjacency metric dimension for G, $\dim_A(G)$, is the cardinality of vertices in an adjacency metric basis for G.

Farthest before concept about adjacency metric dimension has introduced by Jannesari and Omoomi [4], Harary and Melter [2] have been introduced about resolving set in 1976 and independently, Slater [5] introduce this concept in 1975. This concept is a basic concept that must be known when a research results metric dimension of graphs. To prove that set W is resolving set of a graph G, we only present that every vertex in $V(G)\backslash W$ has distinct representation, because vertex y in W is unix vertex with $d(y, y) = 0$.

The following results have proved by Jannesari and Omoomi that used in this reasearch.

Proposition 1.1. [4] *If a graph G is connected, then* $\dim_A(G) \geq \dim(G)$.
Proposition 1.2. [4] *If G is a graph of order n, then*

(i) $\dim_A(G) = 1$ *if and only if* $G = \{P_1, P_2, P_3, \overline{P_2}, \overline{P_3}\}$.

(ii) $\dim_A(G) = n-1$ *if and only if* $G = K_n$ *or* $G = \overline{K_n}$.

In this paper, as G, we use P_n, C_n, K_n and $K_{1,n}$. Motivated by results in [1] and [3], we study and determine the adjacency metric dimension of graphs with pendant points (edge-corona of graphs $G \Diamond H$ when $H = K_1$ and $H = mK_1$ for $m \geq 2$). $G \Diamond H$ is a graph formed by taking G and $k = |E(G)|$ copies of H then joining two end-vertices s_i, s_h of edge $e_j = s_i s_h$ of G to every vertex in the j^{th}-copy of H [6].

II. RESULTS

In the following, we present some useful results on the adjacency metric dimension of graphs with pendant points.

Theorem 2.1. *Let G be a connected graph of order* $n \geq 2$ *and measure* $k \geq 2$. *Then* $\dim_A(G \Diamond K_1) = 2$ *if and only if* $G = \{P_2, P_3, C_3\}$.

Proof. 1). If $G = P_2$ then $G \Diamond K_1 \cong K_3$, so by Proposition 1.2.(ii) we obtain $\dim_A(P_2 \Diamond K_1) = 2$. If $G = P_3$ then $G \Diamond K_1 \cong P_3 \Diamond K_1$. Because $P_3 \Diamond K_1 \notin \{P_1, P_2, P_3, \overline{P_2}, \overline{P_3}\}$, according to Preposition 1.2 (i). $\dim_A(G \Diamond K_1) \geq 2.$ Let $V(P_3) = \{x_1, x_2, x_3\}$ is set vertices of $P_3 \Diamond K_1$ and a_j is a pendant point of $e_j = x_i x_{i+1} \in E(P_3), 1 \leq i = j \leq 2.$ Let $B = \{a_1, a_2\} \subseteq V(P_3 \Diamond K_1).$ Adjacency representations all of vertices from $V(G \Diamond K_1) \backslash B$ are $r_A(x_1|B) = (1,2)$, $r_A(x_2|B) = (1,1)$ and $(x_3|B) = (2,1)$. These adjacency representations are unix. So, $\dim_A(G \Diamond K_1) \leq 2.$ Moreover, if $G = C_3$ then by Preposition 1.2 (i)., we obtain $\dim_A(C_3 \Diamond K_1) \geq 2.$ Let $V(C_3) = \{x_1 = x_4, x_2, x_3\}$ and a_j is a pendant point of edge $e_j = x_i x_{i+1} \in E(C_3),\ 1 \leq i = j \leq 3.$ Let $B = \{a_1, a_2\} \subseteq V(C_3 \Diamond K_1).$
Adjacency representations all of vertices $V(C_3 \Diamond K_1) \backslash B$ are $r_A(x_1|B) = (1,2)$, $r_A(x_2|B) = (1,1)$ and $(x_3|B) = (2,1)$ and $(a_3|B) = (2,2)$. All of these adjacency representations are distinct, as consequence $\dim(C_3 \Diamond K_1) \leq 2.$

2). Now, we will show that if $\dim_A(G \Diamond K_1) = 2.$ then $G = \{P_2, P_3, K_3\}$.

Let $G \Diamond K_1$ be a graph with $\dim_A(G \Diamond K_1) = 2.$ According to definition of edge-corona graph [6], G must have at least an edge, so G is P_2. If G be a graph of order 3 and connected, then certainly G is P_3 or K_3.☐

Theorem 2.2. *Let G be a connected graph of order* $n \geq 4$ *and measure* $k \geq 1$. *Then*

$$\dim_A(G \Diamond K_1) = \begin{cases} k & ,if\ G = K_{1,n}, P_4\ and\ P_5 \\ k-1 & , \qquad otherwise \end{cases}$$

Proof. 1). (A) For $G = K_{1,n}$, let c is a vertex in $V(K_{1,n})$ with degree $|V(K_{1,n})| - 1$, x_i is i^{th}–vertex of $V(K_{1,n}) \backslash \{c\}$ and $a_j,\ 1 \leq j \leq k = n-1$ is a pendant point of edge $e_j = cx_j \in E(K_{1,n}).$

(a).Firstly, we show that $\dim_A(K_{1,n} \Diamond K_1) \leq k.$ Let $W = \{a_j \mid 1 \leq j \leq k = n-1\} \subseteq V(K_{1,n} \Diamond K_1) \backslash \{c\}.$
Representations of all vertices from $V(K_{1,n} \Diamond K_1) \backslash B$ are

$r_A(c\mid B)=(\underbrace{1,1,...,1}_{k\ term})$ and $r_A(x_i\mid B)=(\underbrace{2,...,2,\ \underset{i^{th}-term}{1}\ ,2,...,2}_{k\ term}).$

All of this adjacency representations are distict.

(b). Now, we present that $\dim_A(K_{1,n}\Diamond K_1)\geq k.$ Assume that adjacency basis of $K_{1,n}\Diamond K_1$ is B with $|B|<k$. Then, there exist at least two distinct vertices $u,v\in V(K_{1,n}\Diamond K_1)\setminus(B\bigcup\{c\})$ such that adjacency representation of a vertex u is the same as adjacency representation of a vertex v, that is $r_A(u\mid B)=(\underbrace{2,2,...,2}_{k\ term})=r_A(v\mid B).$

(B). For $G = P_4$ and P_5, we will proof that (i). $\dim_A(P_4\Diamond K_1) = 3$ and (ii). $\dim_A(P_5\Diamond K_1) = 4$ as follows: Let $V(P_4) = \{x_i\mid 1\leq i\leq 4\}$, $V(P_5) = \{x_i\mid 1\leq i\leq 5\}$, a_j is a pendant point of edge $e_j = x_ix_{i+1}\in E(P_4),\ 1\leq i = j\leq 3$ and b_j is a pendant point of edge $e_j = x_ix_{i+1}\in E(P_5),$ $1\leq i = j\leq 4.$

(i). According to Theorem 2.1, $\dim_A(P_4\Diamond K_1)\geq 3$ and $\dim_A(P_5\Diamond K_1)\geq 3$, but any set of three elemen is not resolving set of $P_5\Diamond K_1$. Because a basis element of $P_5\Diamond K_1$ is not element of $V(P_5)$ then without lost of generality take any three distinct vertices $b_1,b_2,b_3\in V(P_5\Diamond K_1)$ and set $W = \{b_1,b_2,b_3\}.$ Then Adjacency representations all of vertices in $V(P_5\Diamond K_1)\setminus W = \{a_4,x_i\mid 1\leq i\leq 5\}$ with respect to W are

$$r_A(x_1\mid W)=(1,2,2),\ r_A(x_2\mid W)=(1,2,1),\ r_A(x_3\mid W)=(2,1,1),$$
$$r_A(x_4\mid W)=(2,1,2),\ r_A(x_5\mid W)=(2,2,2),\ \text{and}\ r_A(a_4\mid W)=(2,2,2).$$

Because $r_A(x_5\mid W)=r_A(a_4\mid W)$ then W is not resolving set of $P_5\Diamond K_1$. So $\dim_A(P_5\Diamond K_1)\geq 4.$

(ii). Now, we present that $\dim_A(P_4\Diamond K_1)\leq 3$ and $\dim_A(P_5\Diamond K_1)\leq 4.$ Let $W_1 = \{a_1,a_2,a_3\}$ and $W_2 = \{b_1,b_2,b_3,b_4\}.$ Adjacency representations of all vertices from $V(P_4\Diamond K_1)-W_1$ with respect to W_1 and $V(P_5\Diamond K_1)-W_5$ with respect to W_2 are

$$r_A(x_1\mid W)=(1,2,2),\ r_A(x_2\mid W)=(1,1,2),\ r_A(x_3\mid W)=(2,1,1),\ r_A(x_1\mid W)=(2,2,1),$$

and

$$r_A(x_1\mid W)=(1,2,2,2),\ r_A(x_2\mid W)=(1,2,1,2),\ r_A(x_3\mid W)=(2,1,1,2),$$
$$r_A(x_4\mid W)=(2,1,2,1),\ r_A(x_5\mid W)=(2,2,2,1).$$

brespectively. All of these adjacency representations are distinct, so $\dim(P_4\Diamond K_1)\leq 3$ and $\dim(P_5\Diamond K_1)\leq 4.$

2) I. For $G = C_n$, here we show that $\dim(C_n\Diamond K_1)=k-1.$ (a) Let $V(C_n)=\{x_1=x_{n+1},x_2,...,x_n\}$ and $E(C_n)=\{x_ix_{i+1}\mid 1\leq i\leq n\}.$ Then $C_n\Diamond K_1$ have $V(C_n\Diamond K_1)=V(C_n)\bigcup\ \{a_i\mid 1\leq i\leq k\},$ $E(C_n\Diamond K_1)=\ E(C_n)\bigcup\{x_ia_i\mid 1\leq i\leq n=k\}\bigcup\{x_{i+1}a_i\mid 1\leq i\leq n=k\}.$ Let $B = \{a_i\mid 1\leq i\leq$ $\leq k-1\}\subseteq V(C_n\Diamond K_1).$ Adjacency representations of vertices from $V(C_n\Diamond K_1)\setminus B$ with respect to B are

$$r_A(a_k\mid B)=(\underbrace{2,2,...,2}_{k-1\ term}),\ r_A(x_1\mid B)=(\underbrace{1,2,...,2}_{k\ term}),\ r_A(x_n\mid B)=(\underbrace{2,2,...,1}_{k\ term}),$$
$$r_A(x_i\mid B)=(\underbrace{2,...,2,\ \underset{i^{th}-term}{1}\ \ \underset{(i+1)^{th}\ term}{1}\ ,2,...,2}_{k\ term}),\ \ 2\leq i\leq k-3$$

All of these adjacency representation are distinct, so $\dim_A(C_n\Diamond K_1)\leq k-1.$

(b). Now, we present that $\dim_A(C_n\Diamond K_1)\geq k-1$. Assume that adjacency basis of $C_n\Diamond K_1$ is $B\subset A=\bigcup_{i=1}^{k}\{a_i\}$, with $|B|<k-1$. Then, there exist at least two distinct vertices $a_i, a_j \in A\setminus B$ such that adjacency representation of vertex a_i is the same as adjacency representation of vertex a_j, that is $r_A(a_i\mid B)=(2,2,...,2)=r_A(a_j\mid B)$. It is a contradiction.

II. For $G = K_n$, here we will show that $\dim(K_n\Diamond K_1)=k-1$. (a) Let a_j is a pendant point of edge e_j, $V(K_n)=\{y_1,y_2,...,y_n\}$ and $E(K_n)=\{e_j=y_iy_h \mid 1\leq i<h\leq n\}$. Then $K_n\Diamond K_1$ has $V(K_n\Diamond K_1)=V(K_n)\bigcup\{a_j\mid 1\leq j\leq k\}$, $E(K_n\Diamond K_1) = E(K_n) \bigcup \{y_ia_j \mid 1\leq i<h\leq n\} \bigcup\{y_ha_j \mid 1\leq h<i\leq n\}$. Let $B=\{a_j\mid 1\leq j\leq k-1\}\subseteq V(K_n\Diamond K_1)$. Adjacency representations of all vertices from $V(K_n\Diamond K_1)\setminus B$ with respect to B are

$$r_A(a_k\mid B)=(\underbrace{2,2,...,2}_{k-1\ term}),\ r_A(x_1\mid B)=(\underbrace{1,2,...,2}_{k-1\ term}),\ r_A(x_n\mid B)=(\underbrace{2,2,...,1}_{k-1\ term}),$$

$$r_A(x_i\mid B)=(\underbrace{2,...,2,\ \underbrace{1}_{i^{th}-term}\ \underbrace{1}_{(i+1)^{th}-term},2,...,2}_{k-1\ term}),\quad 2\leq i\leq k-3$$

All of these adjacency representations are distinct, so $\dim_A(K_n\Diamond K_1)\leq k-1$.

(b). Now, we present that $\dim_A(K_n\Diamond K_1)\geq k-1$. Let $B\subset A=\bigcup_{j=1}^{k}\{a_j\}$, with $|B|<k-1$ be an adjacency resolving set for $K_n\Diamond K_1$. Then, there are at least two distinct vertices that is $a_s, a_t\in A\setminus B$ such that adjacency representation of vertex a_s is the same as adjacency representation of vertex a_t, that is $r_A(a_s\mid B)=(\underbrace{2,2,...,2}_{k-1\ term})=r_A(a_t\mid B)$. It is a contradiction.

III. For $G=P_n$, $n\geq 6$, and $k\geq 5$. Let $V(P_n)=\{x_i\mid 1\leq i\leq n\}$ and $E(P_n)=\{e_i=x_ix_{i+1}\mid 1\leq i\leq n-1\}$ be the set of vertices and the set of edges of P_n respectively. The pendant point of e_i be denote by a_j, $1\leq j\leq k$. There exist two cases:

Case1: When, $n=2m+1$, for $m\in N$. We will show that $W=\{a_1,a_k,a_2,a_{k-1},...,a_{(k/2)+2},a_{(k/2)}\}$ is an adjacency resolving set for $P_n\Diamond K_1$. Adjacency representations of all vertices from $V(P_n\Diamond K_1)$ \W are

$$r_A(a_{(k/2)+1}\mid W)=(\underbrace{2,2,...,2}_{k-1\ term}),$$

$$r_A(x_1\mid W)=(\underbrace{1,2,2,...,2}_{k-1\ term}),$$

$$r_A(x_2\mid W)=(\underbrace{1,2,1,2,2,2,...,2}_{k-1\ term}),$$

$$r_A(x_3\mid W)=(\underbrace{2,2,1,2,1,2,2,2,...,2}_{k-1\ term}),$$

$$\vdots$$

$$r_A(x_m\mid W)=(\underbrace{2,2,...,2,1,2,1}_{k-1\ term}),$$

$$r_A(x_{m+1} \mid W) = (\underbrace{2,2,...,2,2,2,1}_{k-1\ term}),$$
$$r_A(x_{m+2} \mid W) = (\underbrace{2,2,...,2,2,1,2}_{k-1\ term}),$$
$$r_A(x_{m+3} \mid W) = (\underbrace{2,2,...,2,2,1,2,1,2}_{k-1\ term}),$$
$$\vdots$$
$$r_A(x_{n-1} \mid W) = (\underbrace{2,1,2,1,2,2,...,2}_{k-1\ term}),$$
$$r_A(x_n \mid W) = (\underbrace{2,1,2,2,2,...,2}_{k-1\ term}),$$

All of these adjacency representations are different. W is an adjacency resolving set of $P_n \Diamond K_1$ with minimum cardinality, such that W is an adjacency basis of $P_n \Diamond K_1$. Because, assume that $|W| < k$-1. Then, there are two vertices of $P_n \Diamond K_1$ with the same adjacency representation , that is $a_{(k/2)}$ and $a_{(k/2)+1}$ with $r_A(a_{(k/2)}) = (2,2,...,2) = r_A(a_{(k/2)+1})$. Therefore $\dim_A(P_n \Diamond K_1) = k-1$.

Case 2: When, $n = 2m$, for $m \in N$. We will show that $B = \{a_1, a_k, a_2, a_{k-1},..., a_{(k/2)-1}, a_{(k/2)+1}\}$ is an adjacency resolving set of $P_n \Diamond K_1$. Adjacency representations of all vertices from $V(P_n \Diamond K_1) \setminus B$ are

$$r_A(a_{((k-1)/2)+1} \mid B) = (\underbrace{2,2,...,2}_{k-1\ term}),$$
$$r_A(x_1 \mid B) = (\underbrace{1,2,2,...,2}_{k-1\ term}),$$
$$r_A(x_2 \mid B) = (\underbrace{1,2,1,2,2,2,...,2}_{k-1\ term}),$$
$$r_A(x_3 \mid B) = (\underbrace{2,2,1,2,1,2,2,2,...,2}_{k-1\ term}),$$
$$\vdots$$
$$r_A(x_m \mid B) = (\underbrace{2,2,...,2,2,1,2}_{k-1\ term}),$$
$$r_A(x_{m+1} \mid B) = (\underbrace{2,2,...,2,2,2,1}_{k-1\ term}),$$
$$r_A(x_{m+2} \mid B) = (\underbrace{2,2,...,2,2,1,2,1}_{k-1\ term}),$$
$$r_A(x_{m+3} \mid B) = (\underbrace{2,2,...,2,2,1,2,1,2,2}_{k-1\ term}),$$
$$\vdots$$
$$r_A(x_{n-1} \mid B) = (\underbrace{2,1,2,1,2,2,...,2}_{k-1\ term}),$$
$$r_A(x_n \mid B) = (\underbrace{2,1,2,2,2,...,2}_{k-1\ term}).$$

These adjacency representations are distinct. Further, W is a basis adjacency for $P_n \lozenge K_1$. If it is not, assume that cardinality of B, $|B| < k$-1. Then, there are a pair vertices of $P_n \lozenge K_1$ that is $a_{((k-1)/2)}$ and $a_{((k-1)/2)+1}$ with $r_A(a_{((k-1)/2)}) = (2,2,...,2) = r_A(a_{((k-1)/2)+1})$, that cause B is not resolving set for $P_n \lozenge K_1$, a contradicition. Therefore $\dim_A(P_n \lozenge K_1) = k-1$. □

Theorem 2.3. *Let G be a connected graph of order n and measure k. If* $\overline{K_m}$ = mK_1 *is complement of complete graph with* $m \geq 2$ *then* $\dim_A(G \lozenge mK_1) = mk-1$.

Proof. Let x_{1j}, x_{2j} are 1^{th}-endvertex and 2^{nd}-endvertex of j^{th}-edge $e_j = x_{1j}x_{2j} \in E(G)$, and a_j, $1 \leq j \leq k$ is a pendant point of edge $e_j = x_{1j}x_{2j} \in E(G)$. Let $d(u, v)$ is an adjacency distance between two vertices u and v in $G \lozenge K_1$. For every $j \in \{1,2,...,k\}$, every pair.of vertices a, $b \in (\overline{K_m})_j$ satisfy $d_A(a,x) = d_A(b,x)$ for all $x \in V(G \lozenge mK_1) - \{a,b\}$. Moreover, ($\overline{K_m}$) is an adjacency distance similar equivalence class in a connected graph $G \lozenge mK_1$. By observation 1., we obtain $\dim_A(G \lozenge mK_1) \geq mk-1$. Next, we will show that $\dim_A(G \lozenge mK_1) \leq mk-1$. Without lost of generality, choose B = { a_{11}, a_{21}, ..., a_{m1}, a_{12}, a_{22}, ..., a_{m2}, ..., a_{1k}, a_{2k}, ..., $a_{(m-1)k}$} be an adjacency basis of $G \lozenge mK_1$. Adjacency representation of the other vertices in $G \lozenge mK_1$ are

$$r_A(a_{mk}|B) = (\underbrace{2,2,...,2}_{mk-1\ term}),$$

$$r_A(x_{11}|B) = (\underbrace{1,1,...,1}_{m\ term}, \underbrace{2,2,...,2}_{m(k-1)\ term})$$

$$r_A(x_{21}|B) = (\underbrace{1,1,...,1}_{m\, term}, \underbrace{1,1,...,1}_{m\, term}, \underbrace{2,2,...,2}_{m(k-2)})$$

$$r_A(x_{2k}|B) = (\underbrace{2,2,...,2}_{m(k-1)\ term}, \underbrace{1,1,...,1}_{m\, term})$$

$$r_A(x_{1j}|B) = (2,2,...,2, \underbrace{1,1,...,1}_{m\ (j-1)^{th}-term} \underbrace{1,1,...,1}_{m\ (j^{th})-term}, 2,2,...,2), \quad 2 \leq j \leq k. \ r_A(x_{2j}|B) =$$

$$(2,2,...,2, \underbrace{2,2,...,2}_{m\ (j-1)^{th}-term} \underbrace{1,1,...,1}_{m\ (j^{th})-term}, 2,2,...,2), \quad 2 \leq j \leq k.$$

All of these adjacency representations of all vertices $x \in V(G)$ with respect to B are distinct. Then, B is an adjacency resolving set for $G \lozenge mK_1$. So, $\dim_A(G \lozenge mK_1) \leq mk-1$. □

Abstract—The unpredictable extreme rainfall can cause flood. Prediction to this extreme rainfall needs to do, so that the efforts to cope flood can be effective. One of the methods that can predict the extreme rainfall is the Spatial Extreme Value (SEV) with the Max-Stable Process (MSP) approach. One of the important purpose in the Spatial Extreme Value (SEV) is the calculation of return level (the predicted extreme value). The calculation of return level depends on parameter estimation in that method. This research disscusses about parameter estimation of the Spatial Extreme Value (SEV) Max-Stable Process especially Smith Model. Parameter estimation is done by using the methods of Maximum Composite Likelihood Estimation (MCLE) dan Maximum Pairwise Likelihood Estimation (MPLE). If the result of estimation using this method is not closed form, it must be continued by using numerical iteration method. The iteration method used in this research is the Broyden-Fletcher Goldfarb-Shanno (BFGS) Quasi Newton, that fastly to be convergence than other methods. The result of parameter estimation will be applied in the rainfall data of Ngawi Regency which is the Regency with the largest rice production in East Java Province (the provice with the largest rice farm in Indonesia).

Keywords : *BFGS Quasi Newton, Smith Model, Max-Stable Process, likelihood estimation, precipitation extreme, return level.*

I. INTRODUCTION

Lamongan Regency is a regency which has the largest rice farm in East Java. Amongan Regency is also included the area which is often attacked by flood. The unpredictable extreme rainfallis the cause of this disaster. Based on the reason, the extreme rainfall prediction needs to be done in Lamongan Regency.

One method to predict extreme rainfall value is *Spatial Extreme Value* (SEV). SEV Method handles the case of extreme happening (like the extreme raifall) by considering dependency between happening in a region and another region[1]. The value of these extreme happenings are counted in a distribution *Generalized Extreme Value* (GEV), it is distribution which considering the shape of tail of data distribution [2]. SEV can be approached by *Max-Stable Process* (MSP) [3]. MSP uses *Block Maxima* (BM) method in choosingthe extreme values of all cases data.

The main goal of SEV is to acquire *return level (prediction value of extreme happening)*. *Return level*can be acquired when a number of parameter estimators are known. Parameter estimation method which is mostly proposed by the previous researchers are *Maximum Composite Likelihood Estimation* (MCLE) and *Maximum PairwiseLikelihood Estimation* (MPLE) by [4], [5], [6].

This research estimates parameter toward *Max-Stable Process* (MSP), which involves one of its model, it is *Smith*Model. If the result of parameter estimation is not *close form,* so that it must be continued by using numerical iteration method, in research, it will be used iteration method of *Broyden-Fletcher Goldfarb-Shanno* (BFGS) *Quasi Newto,* by considering that iteration in this method is faster to reach convergency than the other methods [7].

II. REFERENCE OVERVIEW

A. Extreme Value Theory (EVT)

Extreme Value Theory (EVT) is a theory which studies about the probability of extreme happenings by focusing on the tail behavior of a distribution [2]. The tail behavior which declines slowly (the fat tail shape) indicates the existance of probability of extreme happenings. The fatter the tail of distribution is, the bigger the brobability of extreme value to appear. [8] and [9] explains that there are two methods of defining extreme value. They are BM and*Peak Over Threshold* (POT).

Extreme Value theory involves a distribution for generalizing extreme data into distribution of GEV[10]. X~GEV(μ, α, ξ) has the form of *Probability Density Function* (PDF)

$$f(X;\mu,\sigma,\xi) = \begin{cases} \frac{1}{\sigma}\left[1+\xi\frac{(X-\mu)}{\sigma}\right]^{-\frac{1}{\xi}-1}\exp\left(-\left[1+\xi\frac{(X-\mu)}{\sigma}\right]^{-1/\xi}\right), & \xi \neq 0 \\ \frac{1}{\sigma}\exp\left(-\frac{X-\mu}{\sigma}\right)\exp\left(-\exp\left[-\frac{(X-\mu)}{\sigma}\right]\right), & \xi = 0 \end{cases} \quad (2)$$

X is variable of observation, μ is parameter of location, σ is parameter of scale, $\sigma > 0$, and ξ is parameter of shape. Parameter ξ indicates tail behavior of GEV. Based on parameter ξ, GEV distribution follows Gumbel distribution when $\xi = 0$, follows Frechet distribution when $\xi > 0$, and follows Weibull distribution when $\xi < 0$.

B. Block Maxima (BM)

BM is extreme value identification method based on the formation of period blocks. The data of observation are devided into certain blocks. Based on the formed blocks, it is choosen the maximum value of observation of each block. The choosen maximum value of each block belongs to extreme sample. Extreme value which is taken using BM method follows GEV distribution [8].

C. Spatial Extreme Value (SEV)

There are many data of observation connected with natural happening, they are the data from a happening in a small area in the larger area. Based on the data, it is possible that there is dependency between one spot to another spot in one area of happening. The nearer the distance (h) between locations, it is possible that there is dependency which is more stronger. The distance between locations (s) to-j and to-k can be counted by using distance measurement with equation of

$$h_{j,k} = \| s_j - s_k \| \quad (3)$$

D. Max-Stable Process (MSP)

MSP is stocastical process, the enlargement of distribution of *multivariate extreme value* to the infinity dimension. $\{Z(s)\}_{s\epsilon R^d}$ is said *max-stable* if a constant$a_n(s) > 0$ and $b_n(s) \in$ R, so

$$Z(s) = \lim_{n\to+\infty}\frac{\max_{i=1}^{n}\{x_i(s)\}-b_n(s)}{a_n(s)},\ n\to\infty, s\in R^d \quad (4)$$

$x_i(s)$ distributes identical independent random [6].

Z(s) is said *max-stable*if and only follows distribution of GEF which constitutes distribution for extreme happening data. Frechet distribution has the fattest shape of tail compared with Gumbel dan Weibull distribution. So, if $a_n(s) = n$, $b_n(s) = 0$, $Z(s) = 0$, $Z(s)$ can be generalized into Frechet unit.

$$F(X) = \exp(-\frac{1}{Z}),\ Z > 0 \quad (5)$$

[9] mentions that Z constitutes the form of transformation of X, with transformation function of

$$Z = \left(1 + \xi \frac{X-\mu}{\sigma}\right)_+^{1/\xi} \tag{6}$$

whereas $a_+ = \max(0; a)$.

E. Model Smith

CDF Model of *Smith* is

$$F(Z_j, Z_k)=exp\left\{-\frac{1}{Z_j}\Phi\left(\frac{a(h)}{2}+\frac{1}{a(h)}log\left[\frac{Z_k}{Z_j}\right]\right)-\frac{1}{z_k}\Phi\left(\frac{a(h)}{2}+\frac{1}{a(h)}log\left[\frac{Z_j}{Z_k}\right]\right)\right\} \tag{9}$$

Z_j is variable Z locationto-j, Z_k is variable Z locationto-k,Φ is CDF bivariat normal standart, $a(\boldsymbol{h_{j,k}})$ is $\sqrt{\boldsymbol{h_{j,k}}^T \boldsymbol{\Sigma_{j,k}}^{-1} \boldsymbol{h_{j,k}}}$, and $\boldsymbol{\Sigma_{j,k}}$ is matrix covarian of location variable to-j and to-k.

F. Koefisien Ekstremal

Extremal coeficient constitutes coeficient used to see dependency level between one variable with another variable. Extremal coeficient of *Smith* Model MSP has the range of value $1 \le \theta(\boldsymbol{h_{j,k}}) \le 2$. The more approaching the value of $\Theta(\boldsymbol{h_{j,k}})$ to 1 indicates the more dependent between the two variables. Extremal coeficient of *Smith* MSP Model is [11]

$$\Theta(\boldsymbol{h_{j,k}}) = 2\Phi\left(\sqrt{\boldsymbol{h_{j,k}}^T \boldsymbol{\Sigma_{j,k}}^{-1} \boldsymbol{h_{j,k}}}/2\right) \tag{10}$$

G. Takeuchi Information Criterion (TIC)

The result of parameter estimation *of Smith* produces the value of $\boldsymbol{\beta}$ which is used to form *trend surface* model. *Trend surface model* is linear model which combines coordinate variable of one spot or location, it constitutes *lon* (*longitude*) variable and *lat* (*latitude*) variable, parameter of $\boldsymbol{\beta}$. Moreover the best *trend surface* model of a number of combination is used for estimating *return level.* Determination of the best *trend surface* model is done by counting the value of TIC. Model with the least TIC value constitutes the best model [12].

$$\text{TIC} = -2\, lp(\boldsymbol{\beta}) + 2\ \text{tr}\ [\ \text{H}(\boldsymbol{\beta})^{-1}\ \text{J}(\boldsymbol{\beta})] \tag{11}$$

With :

$l_p(\boldsymbol{\beta})$ = function *ln pairwise likelihood* $\sum_{j=1}^{m-1}\sum_{k=j+1}^{m} ln\, f(Z_j, Z_k; \boldsymbol{\beta})$

$H(\boldsymbol{\beta})^{-1}$ = $-\ lim_{n\to\infty} n^{-1}\frac{\partial^2 l_p(\boldsymbol{\beta})}{\partial\boldsymbol{\beta}\,\partial\boldsymbol{\beta}^{\mathrm{T}}}$

$J(\boldsymbol{\beta})$ = $cov\left[n^{-1/2}\frac{\partial l_p(\boldsymbol{\beta})}{\partial\boldsymbol{\beta}}\right]$

H. Return Level

Return level is maximum value which can be achieved in certain period. *Return level* value constitutes the extreme value of prediction. *Return level* for a location (s) is [8]

$$z_p(s) = \hat{\mu}(s) - \frac{\hat{\sigma}(s)}{\hat{\xi}(s)}\left(1 - \left[-\ln\left(1-\frac{1}{\mathrm{T}}\right)\right]^{-\hat{\xi}(s)}\right) \tag{12}$$

T is the number of blocks in one interval of the predicted period. The achieved probability of $z_p(s)$ is $p = \mathrm{P}(\mathrm{X} > z_p) = \frac{1}{T}$.

I. Maximum Likelihood Estimation (MLE)

The function of *likelihood* $L(\boldsymbol{\Theta})$ for independent random sample *X* having measurement of *n* from PDF $f(X;\boldsymbol{\Theta})$ is

$$L(\boldsymbol{\Theta}) = \prod_{i=1}^{n} f(X;\boldsymbol{\Theta}) = f(x_1;\boldsymbol{\Theta})\ f(x_2;\boldsymbol{\Theta}) \ldots\ f(x_n;\boldsymbol{\Theta}) \tag{13}$$

Estimator of parameter of $\boldsymbol{\Theta}$ ($\boldsymbol{\Theta}$ in this research is parameter of $\boldsymbol{\mu}$, $\boldsymbol{\sigma}$, and $\boldsymbol{\xi}$) is acquired from counting the first deferential of the function and equalizes it with zero.

$$\frac{\partial\, ln\, L(\boldsymbol{\Theta})}{\partial \boldsymbol{\Theta}} = 0 \tag{14}$$

if and only if

$$\frac{\partial L(\boldsymbol{\Theta})}{\partial \boldsymbol{\Theta}} = 0 \tag{15}$$

So, it can be acquired the maximum estimator of $\boldsymbol{\Theta}$ more easily by the counting in $ln\ L(\boldsymbol{\Theta})$ [13].

J. Maximum Composite Likelihood Estimation (MCLE)

MCLE method can siplify the counting substantially and produce the expected estimators, they have the characters unbias, consintent, and normal [14]. The same as *Maximum Pairwise Likelihood Estimation* (MPLE), this method basically changes the use of higher dimension PDF into lower dimension PDF. MPLE involves 2 dimensions (2 variables), mean while MCLE involves PDF of variables which are considered independent. This *likelihood* methodis also called the independent *likelihood* method. The function of *compositelikelihood* with *m* location variables and parameter$\boldsymbol{\beta}$ ($\boldsymbol{\beta}$ in this research is parameters $\boldsymbol{\beta}_{\mu}, \boldsymbol{\beta}_{\sigma}, \boldsymbol{\beta}_{\xi}$) can be written as [15] :

$$Lc(\boldsymbol{\beta}) = \prod_{i=1}^{n} L_i(\boldsymbol{\beta})^{w_n} \tag{16}$$

with w_m is nonnegatif optional weighting, so if w_m= 1, the function of *composite likelihood* will be

$$Lc(\boldsymbol{\beta}) = \prod_{i=1}^{n} L_i(\boldsymbol{\beta}) \tag{17}$$

with

$$L(\boldsymbol{\beta}) = \prod_{j=1}^{m} f(\boldsymbol{\beta}) \tag{18}$$

K. Maximum Pairwise Likelihood Estimation (MPLE)

MPLE is parameter estimation method using the function of density *pairwise* or in pair of two variables. MPLE method replaces the function ($L(\boldsymbol{\beta})$) in MLE with the function of *pairwise likelihood* $L_p(\boldsymbol{\beta})$.

$$L_p(\boldsymbol{\beta}) = \prod_{i=1}^{n} \prod_{j=1}^{m-1} \prod_{k=j+1}^{m} f\left(x_{ji}, x_{ki}; \boldsymbol{\beta}\right) \tag{19}$$

$f\left(x_{ji}, x_{ki}; \boldsymbol{\beta}\right)$ constitutes PDF bivariat with parameter $\boldsymbol{\beta}$ and i = 1, 2, … n is observation on each variable [9].

L. Broyden-Fletcher Goldfarb-Shanno (BFGS) Quasi Newton

Numerical iterasion method BFGS *Quasi Newton* constitutes the improvement of *Newton Iteration Method*. This Method is introduced by [16], [17], [18], and [19]. The equation of iteration method BFGS*Quasi Newton*is :

$$\underset{\sim}{\boldsymbol{\theta}}^{(k+1)} = \underset{\sim}{\boldsymbol{\theta}}^{(k)} + \alpha^{(k)} S^{(k)} \tag{20}$$

$\underset{\sim}{\boldsymbol{\theta}}^{(k)}$ = initial value
$H\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right)^{-1}$ = invers of Hessian matrix
$g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right)$ = matrix which elements contain the first deferential of $\underset{\sim}{\boldsymbol{\theta}}^{(k)}$.

whereas $\alpha^{(k)}$ constitutes the function for minimizing *error.*

$$\alpha^{(k)} = \arg\min\left[f\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)} + \alpha^{(k)} S^{(k)}\right)\right] \tag{21}$$

$$S^{(k)} = -(H^{(k)}) g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right) \tag{22}$$

Then counting the change $\Delta\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right) = \alpha^{(k)} S^{(k)}$ and

$$\Delta g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right) = g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k+1)}\right) - g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right) \tag{23}$$

so will be acquired the equation of

$$H^{(k+1)} = H^{(k)} + \left(1 + \frac{\Delta g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right)^T H^{(k)} \Delta g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right)}{\Delta g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right)^T \Delta \underset{\sim}{\boldsymbol{\theta}}^{(k)}}\right) \frac{\Delta \underset{\sim}{\boldsymbol{\theta}}^{(k)} \Delta \underset{\sim}{\boldsymbol{\theta}}^{(k)T}}{\Delta \underset{\sim}{\boldsymbol{\theta}}^{(k)T} \Delta g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right)} - \frac{H^{(k)} \Delta g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right) \Delta \underset{\sim}{\boldsymbol{\theta}}^{(k)T} + \left(H^{(k)} \Delta g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right) \Delta \underset{\sim}{\boldsymbol{\theta}}^{(k)T}\right)^T}{\Delta g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right)^T \Delta \underset{\sim}{\boldsymbol{\theta}}^{(k)}} \tag{24}$$

$H^{(k)}$ is simetricaland nonsingular matrix. $H^{(0)}$ is choosen by identical matrix which renewed by (24) in the next iteration [20]. Iteration is done until $|\underset{\sim}{\boldsymbol{\theta}}^{(k+1)} - \underset{\sim}{\boldsymbol{\theta}}^{(k)}| \le e$ with *e* is the very small figure [21].

M. Anderson DarlingTest

Anderson Darling Test is a test used to find out whether a date follows certain distribution. GEV distribution testing toward two extremes can be done by using Anderson Darling test with the following procedure [22] :

1. Hypothesis formulation :
   H_0 : $F(x) = F^*(x)$ (Data followstheoritical distribution $F^*(x)$)
   H_1 : $F(x) \neq F^*(x)$ (Data doesn't followtheoritical distribution $F^*(x)$)

   In the case of rainfall, theoritical distribution used is GEV distribution
2. Statistics test

$$AD = -n - \frac{1}{n}\sum_{i=1}^{n}(2i-1)\left(ln(x_i) + ln(1-(x_{n+1-i}))\right) \tag{25}$$

   $F(X)$ is CDF of sample data
   $F^*(X)$ is theoritica CDF
3. Criterion of tes
   Ignore H_0 if AD>critical value of AD tabel, or *p-value* < *α*.

N. Rainfal

Rainfall isthe altitude of rainwater compiledin a rainmeteron theflat place, not to absorb, not to permiate, and not toflow. Extreme raifall is rainfall which has intensity of >100 milimeter per day. Rainfall with intensity of > 50 milimeter per day constitutes heavy rainfall. Based on the classification of monthly average rainfall distribution pattern inall Indonesia areaconsists of 342 Zone of Season patterns,

ISBN 978-602-74529-0-9

and 65 Non Zone of Season. Zone of Season is an area which average rain pattern has clear limit climatologically between dry season period and rainy season period. Oneregency or city may consist of some Zone of Season. Non Zone of Season is areas which doesn't have the clear limit climatologically between rainy season periodand dry season [23].

III. DISCUSSION

Calculation of *retun level* needs a number of estimator namely $\hat{\mu}(s)$, $\hat{\sigma}(s)$, and $\hat{\xi}(s)$ which values have been counted first through a Trend Surface Model. Trend Surface Model

$$\mu(x) = \beta 0,\ +\beta 1,\mu lon(s) + \beta 2,\mu lat(s)$$
$$\sigma(x) = \beta 0,\sigma + \beta 1,\sigma lon(s) + \beta 2,\sigma lat(s)$$
$$\xi(x) = \beta 0,\xi$$

in its calculation needs the values of parameter β (β_0, β_1, β_2) which must be estimated first from Smith Model. Estimation process of Smith Model's parameter it self needs the values of estimator $\mu(x)$, $\sigma(x)$, and $\xi(x)$ which is acquired by doingestimation to GEV distribution parameter.

A. GEV Distribution Parameter Estimation

1. Arranging the function of likelihood of PDF GEV

$$L(\mu,\sigma,\xi) = \prod_{i=1}^{n} f(x_i)$$
$$= \left(\frac{1}{\sigma}\right)^n \prod_{i=1}^{n} \left\{ \left[1+\xi \frac{x_i-\mu}{\sigma}\right]^{-\frac{1}{\xi}-1} \right\} \exp\left(-\sum_{i=1}^{n}\left[1+\xi\frac{x_i-\mu}{\sigma}\right]^{-\frac{1}{\xi}}\right).$$

2. Function of *likelihood* is carried out in the form of ln

$$\ell(\mu,\sigma,\xi) = -n\ln\sigma - \left(1+\frac{1}{\xi}\right)\sum_{i=1}^{n}\ln\left[1+\xi\frac{x_i-\mu}{\sigma}\right] - \sum_{i=1}^{n}\left[1+\xi\frac{x_i-\mu}{\sigma}\right]^{-\frac{1}{\xi}}$$

3. Derivation of function of *likelihood* toward parameter needs to be estimated
   a. *Derivation toward parameterμ*

$$\frac{\partial\ell(\mu,\sigma,\xi)}{\partial\mu} = \left(\frac{1+\xi}{\sigma}\right)\sum_{i=1}^{n}\left[1+\xi\left(\frac{x_i-\mu}{\sigma}\right)\right]^{-1} - \frac{1}{\sigma}\sum_{i=1}^{n}\left[1+\xi\left(\frac{x_i-\mu}{\sigma}\right)\right]^{-\frac{1}{\xi}-1} = 0$$

   b. Derivation toward parameter σ

$$\frac{\partial\ell(\mu,\sigma,\xi)}{\partial\sigma} = -\frac{n}{\sigma} + (1+\xi)\sum_{i=1}^{n}\left(\frac{x_i-\mu}{\sigma^2}\right)\left(1+\xi\left(\frac{x_i-\mu}{\sigma}\right)\right)^{-1}$$
$$-\sum_{i=1}^{n}\left(\frac{x_i-\mu}{\sigma^2}\right)\left[1+\xi\left(\frac{x_i-\mu}{\sigma}\right)\right]^{-\frac{1}{\xi}-1} = 0$$

   c. Derivation toward parameter ξ

$$\frac{\partial \ell(\mu,\sigma,\xi)}{\partial \xi}=\frac{1}{\xi^2}\sum_{i=1}^{n}\ln\left[1+\xi\left(\frac{x_i-\mu}{\sigma}\right)\right]-\left(\frac{1}{\xi}+1\right)\sum_{i=1}^{n}\left[1+\xi\left(\frac{x_i-\mu}{\sigma}\right)\right]^{-1}\left(\frac{x_i-\mu}{\sigma}\right)$$

$$-\sum_{i=1}^{n}\left[1+\xi\left(\frac{x_i-\mu}{\sigma}\right)\right]^{-\frac{1}{\xi}}\left[\frac{1}{\xi^2}\sum_{i=1}^{n}\ln\left[1+\xi\left(\frac{x_i-\mu}{\sigma}\right)\right]-\frac{1}{\xi}\sum_{i=1}^{n}\frac{\left(\frac{x_i-\mu}{\sigma}\right)}{1+\xi\left(\frac{x_i-\mu}{\sigma}\right)}\right]=0$$

Estimation using MLE gives a result in the form of equation which is not *closed form.* This equation can not be used to arrange function which can estimate parameter. Based on this reason, the estimation of parameter must be continued by using numerical iteration. Numerical iteration used in this research is BFGS Quasi Newton.

B. Smith Model Parameter Estimation using MCLE

Function of *composite like lihood* with *m* variables

$$Lc(\boldsymbol{\beta}) = \prod_{i=1}^{n} L_i(\boldsymbol{\beta})$$

with $L(\boldsymbol{\beta}) = \prod_{j=1}^{m} f(\boldsymbol{\beta})$, indicatesthat as many as *m* variables MCLE involvolves PDF of variables which is considered as independent, never theless, this *likelihood* method is also called independent *likelihood* method.

In the case of spatial, variable of rainfallas many as *m* locationis considered as mutual dependent, related to appropriate with how far is it the distance between locations. Variable of rainfall on as many as *m* locations considered as variable *m* variable rain fall which is dependent. It is not appropriate with MCLE method which involves *m* involved variables which is independent. Never theless, Smith Model parameter estimation is not appropriate to use MCLE method.

C. Smith Model Parameter Estimation Using MPLE

1. Arranging PDF Smith Model based on CDF Smith Model

$$F(Z_j,Z_k) = exp\left\{-\frac{1}{Z_j}\Phi\left(\frac{a(h)}{2}+\frac{1}{a(h)}log\left[\frac{Z_k}{Z_j}\right]\right)-\frac{1}{z_k}\Phi\left(\frac{a(h)}{2}+\frac{1}{a(h)}log\left[\frac{Z_j}{Z_k}\right]\right)\right\}$$

If

$$w=\frac{a}{2}+\frac{1}{a}\log\left(\frac{z_k}{z_j}\right)$$

$$v=\frac{a}{2}+\frac{1}{a}\log\left(\frac{z_j}{z_k}\right)$$

$j = 1, 2, \ldots, m-1$ end $k = 2, 3, \ldots, m$

CDF Smith Model can be written as

$$F(\mathrm{Z}_j,\mathrm{Z}_k)=\exp\left(-\frac{\Phi w}{Z_j}-\frac{\Phi)}{Z_k}\right)$$

$$f(z_j, z_k) = \frac{\partial^2}{\partial z_j \partial z_k} F(z_j, z_k)$$

$$= \exp\left(-\frac{\Phi w}{z_j} - \frac{\Phi v}{z_k}\right) \times \left\{\left(\frac{\Phi w}{z_j^2} + \frac{\varphi w}{a z_j^2} - \frac{\varphi v}{a z_j z_k}\right)\right.$$

$$\left. \times \left(\frac{\Phi v}{z_k^2} + \frac{\varphi v}{a z_k^2} - \frac{\varphi w}{a z_j z_k}\right) + \left(\frac{v \varphi w}{a^2 z_j^2 z_k} + \frac{w \varphi v}{a^2 z_j z_k^2}\right)\right\}$$

2. Arranging the function of *pairwise likelihood* of PDFSmith Model

$$L_p(\boldsymbol{\beta}) = \sum_{j=1}^{M-1} \sum_{k=j+1}^{M} f(z_j, z_k)$$

$$= \sum_{j=1}^{M-1} \sum_{k=j+1}^{M} \left(\exp\left(-\frac{\Phi w}{z_j} - \frac{\Phi v}{z_k}\right) \times \left\{\left(\frac{\Phi w}{z_j^2} + \frac{\varphi w}{a z_j^2} - \frac{\varphi v}{a z_j z_k}\right)\right.\right.$$

$$\left.\left. \times \left(\frac{\Phi v}{z_k^2} + \frac{\varphi \mathrm{v}}{a z_k^2} - \frac{\varphi \mathrm{w}}{a z_j z_k}\right) + \left(\frac{v \varphi w}{a^2 z_j^2 z_k} + \frac{w \varphi v}{a^2 z_j z_k^2}\right)\right\}\right)$$

Based on this function, there haven't been parameter $\boldsymbol{\beta}$ which will be estimated. Nevertheless, parameter $\boldsymbol{\beta}$ is appeared by elaborating upon variable Z with its function of transformation.

$$Z = \left(1 + \xi \frac{X - \mu}{\sigma}\right)^{1/\xi}$$

In this stage estimation involves variabel X, so it must be formed a function of pairwise using fungction of this variables by using equation of

$$f(X_j, X_k) = f_{Z_j, Z_k}\left[g^{-1}(X_j, X_k)\right] \left|J(X_j, X_k)\right|$$

$$\left|J(X_j, X_k)\right| = \frac{1}{\sigma_j \sigma_k} \left(1 + \frac{\xi_j (X_j - \mu_j)}{\sigma_j}\right)_+^{1/\xi_j - 1} \times \left(1 + \frac{\xi_k (X_k - \mu_k)}{\sigma_k}\right)_+^{1/\xi_k - 1}$$

Resulting

$$
\begin{aligned}
f(X_j, X_k) = & \left(\exp\left(-\frac{\Phi w}{\left(1+\frac{\xi_j (X_j-\mu_j)}{\sigma_j}\right)_+^{1/\xi_j}} - \frac{\Phi v}{\left(1+\frac{\xi_k (X_k-\mu_k)}{\sigma_k}\right)_+^{1/\xi_k}} \right) \right. \\
& \times \left(\frac{\Phi w}{\left(1+\frac{\xi_j (X_j-\mu_j)}{\sigma_j}\right)_+^{2/\xi_j}} + \frac{\varphi w}{a\left(1+\frac{\xi_j (X_j-\mu_j)}{\sigma_j}\right)_+^{2/\xi_j}} - \frac{\varphi v}{a\left(1+\frac{\xi_j (X_j-\mu_j)}{\sigma_j}\right)_+^{1/\xi_j}\left(1+\frac{\xi_k (X_k-\mu_k)}{\sigma_k}\right)_+^{1/\xi_k}} \right) \\
& \times \left(\frac{\Phi v}{\left(1+\frac{\xi_k (X_k-\mu_k)}{\sigma_k}\right)_+^{2/\xi_k}} + \frac{\varphi \mathrm{v}}{a\left(1+\frac{\xi_k (X_k-\mu_k)}{\sigma_k}\right)_+^{2/\xi_k}} - \frac{\varphi \mathrm{w}}{a\left(1+\frac{\xi_j (X_j-\mu_j)}{\sigma_j}\right)_+^{1/\xi_j}\left(1+\frac{\xi_k (X_k-\mu_k)}{\sigma_k}\right)_+^{1/\xi_k}} \right) \\
& \left. + \left(\frac{v\varphi w}{a^2\left(1+\frac{\xi_j (X_j-\mu_j)}{\sigma_j}\right)_+^{2/\xi_j}\left(1+\frac{\xi_k (X_k-\mu_k)}{\sigma_k}\right)_+^{1/\xi_k}} + \frac{w\varphi v}{a^2\left(1+\frac{\xi_j (X_j-\mu_j)}{\sigma_j}\right)_+^{1/\xi_j}\left(1+\frac{\xi_k (X_k-\mu_k)}{\sigma_k}\right)_+^{2/\xi_k}} \right) \right) \\
& \times \left(\frac{1}{\sigma_j \sigma_k} \left(1+\frac{\xi_j (X_j-\mu_j)}{\sigma_j}\right)_+^{1/\xi_j - 1} \times \left(1+\frac{\xi_k (X_k-\mu_k)}{\sigma_k}\right)_+^{1/\xi_k - 1} \right)
\end{aligned}
$$

$$
\begin{aligned}
L_p(\boldsymbol{\beta}) = & \sum_{j=1}^{M-1} \sum_{k=j+1}^{M} \left(\exp\left(-\frac{\Phi w}{\left(1+\frac{\xi_j (X_j-\mu_j)}{\sigma_j}\right)_+^{1/\xi_j}} - \frac{\Phi v}{\left(1+\frac{\xi_k (X_k-\mu_k)}{\sigma_k}\right)_+^{1/\xi_k}} \right) \right. \\
& \times \left\{ \left(\left(\frac{\Phi w}{\left(1+\frac{\xi_j (X_j-\mu_j)}{\sigma_j}\right)_+^{2/\xi_j}} + \frac{\varphi w}{a\left(1+\frac{\xi_j (X_j-\mu_j)}{\sigma_j}\right)_+^{2/\xi_j}} - \frac{\varphi v}{a\left(1+\frac{\xi_j (X_j-\mu_j)}{\sigma_j}\right)_+^{1/\xi_j}\left(1+\frac{\xi_k (X_k-\mu_k)}{\sigma_k}\right)_+^{1/\xi_k}} \right) \right) \right\} \\
& \times \left(\frac{\Phi v}{\left(1+\frac{\xi_k (X_k-\mu_k)}{\sigma_k}\right)_+^{2/\xi_k}} + \frac{\varphi \mathrm{v}}{a\left(1+\frac{\xi_k (X_k-\mu_k)}{\sigma_k}\right)_+^{2/\xi_k}} - \frac{\varphi \mathrm{w}}{a\left(1+\frac{\xi_j (X_j-\mu_j)}{\sigma_j}\right)_+^{1/\xi_j}\left(1+\frac{\xi_k (X_k-\mu_k)}{\sigma_k}\right)_+^{1/\xi_k}} \right) \\
& \left. + \left(\frac{v\varphi w}{a^2\left(1+\frac{\xi_j (X_j-\mu_j)}{\sigma_j}\right)_+^{2/\xi_j}\left(1+\frac{\xi_k (X_k-\mu_k)}{\sigma_k}\right)_+^{1/\xi_k}} + \frac{w\varphi v}{a^2\left(1+\frac{\xi_j (X_j-\mu_j)}{\sigma_j}\right)_+^{1/\xi_j}\left(1+\frac{\xi_k (X_k-\mu_k)}{\sigma_k}\right)_+^{2/\xi_k}} \right) \right) \\
& \times \left(\frac{1}{\sigma_j \sigma_k} \left(1+\frac{\xi_j (X_j-\mu_j)}{\sigma_j}\right)_+^{1/\xi_j - 1} \times \left(1+\frac{\xi_k (X_k-\mu_k)}{\sigma_k}\right)_+^{1/\xi_k - 1} \right)
\end{aligned}
$$

3. Function of *pairwise likelihood* is carried out into the form of ln

$$\ln\left[L_p(\boldsymbol{\beta})\right]=\ln\left[\begin{array}{l}\sum_{j=1}^{M-1}\sum_{k=j+1}^{M}\left(\exp\left(-\frac{\Phi w}{\left(1+\frac{\xi_j(X_j-\mu_j)}{\sigma_j}\right)_+^{1/\xi_j}}-\frac{\Phi v}{\left(1+\frac{\xi_k(X_k-\mu_k)}{\sigma_k}\right)_+^{1/\xi_k}}\right)\right.\\ \times\left\{\left(\left(\frac{\Phi w}{\left(1+\frac{\xi_j(X_j-\mu_j)}{\sigma_j}\right)_+^{2/\xi_j}}+\frac{\varphi w}{a\left(1+\frac{\xi_j(X_j-\mu_j)}{\sigma_j}\right)_+^{2/\xi_j}}-\frac{\varphi v}{a\left(1+\frac{\xi_j(X_j-\mu_j)}{\sigma_j}\right)_+^{1/\xi_j}\left(1+\frac{\xi_k(X_k-\mu_k)}{\sigma_k}\right)_+^{1/\xi_k}}\right)\right\}\right)\\ \times\left(\frac{\Phi v}{\left(1+\frac{\xi_k(X_k-\mu_k)}{\sigma_k}\right)_+^{2/\xi_k}}+\frac{\varphi \mathrm{v}}{a\left(1+\frac{\xi_k(X_k-\mu_k)}{\sigma_k}\right)_+^{2/\xi_k}}-\frac{\varphi \mathrm{w}}{a\left(1+\frac{\xi_j(X_j-\mu_j)}{\sigma_j}\right)_+^{1/\xi_j}\left(1+\frac{\xi_k(X_k-\mu_k)}{\sigma_k}\right)_+^{1/\xi_k}}\right)\\ +\left(\frac{v\varphi w}{a^2\left(1+\frac{\xi_j(X_j-\mu_j)}{\sigma_j}\right)_+^{2/\xi_j}\left(1+\frac{\xi_k(X_k-\mu_k)}{\sigma_k}\right)_+^{1/\xi_k}}+\frac{w\varphi v}{a^2\left(1+\frac{\xi_j(X_j-\mu_j)}{\sigma_j}\right)_+^{1/\xi_j}\left(1+\frac{\xi_k(X_k-\mu_k)}{\sigma_k}\right)_+^{2/\xi_k}}\right)\Bigg)\Bigg)\\ \times\left(\frac{1}{\sigma_j\sigma_k}\left(1+\frac{\xi_j(X_j-\mu_j)}{\sigma_j}\right)_+^{1/\xi_j-1}\times\left(1+\frac{\xi_k(X_k-\mu_k)}{\sigma_k}\right)_+^{1/\xi_k-1}\right)\end{array}\right]$$

$$\mu = d^T\beta_\mu = [1 \quad d1 \quad d2]\begin{bmatrix}\beta_{0,\mu}\\ \beta_{1,\mu}\\ \beta_{2,\mu}\end{bmatrix}$$

$$\sigma = d^T\beta_\sigma = [1 \quad d1 \quad d2]\begin{bmatrix}\beta_{0,\sigma}\\ \beta_{1,\sigma}\\ \beta_{2,\sigma}\end{bmatrix}$$

$$\xi = \beta_{0,\sigma}$$

The last MPLE estimation process is derivation of function ln *pairwise likelihood* toward $\beta_\mu, \beta_\sigma, \beta_\xi$..

D. Quasi Newton BFGS Iteration Algorithm

1. Determininginitial value $\underset{\sim}{\boldsymbol{\theta}}^{(0)}$ which can be filled with matrix in size of *m with* all its member is zero
2. Determining $\alpha^{(k)} = \arg\min\left[f\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)} + \alpha^{(k)} S^{(k)}\right)\right]$
3. Determining matrix $\boldsymbol{H}^{(k+1)}$

$$H^{(k+1)} = H^{(k)} + \left(1 + \frac{\Delta g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right)^{T} H^{(k)} \Delta g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right)}{\Delta g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right)^{T} \Delta \underset{\sim}{\boldsymbol{\theta}}^{(k)}}\right) \frac{\Delta \underset{\sim}{\boldsymbol{\theta}}^{(k)} \Delta \underset{\sim}{\boldsymbol{\theta}}^{(k)T}}{\Delta \underset{\sim}{\boldsymbol{\theta}}^{(k)T} \Delta g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right)}$$
$$- \frac{H^{(k)} \Delta g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right) \Delta \underset{\sim}{\boldsymbol{\theta}}^{(k)T} + \left(H^{(k)} \Delta g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right) \Delta \underset{\sim}{\boldsymbol{\theta}}^{(k)T}\right)^{T}}{\Delta g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right)^{T} \Delta \underset{\sim}{\boldsymbol{\theta}}^{(k)}}$$

with

$H^{(0)} = I$ (matrix identity in size of m)

$\Delta g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right) = g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k+1)}\right) - g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right)$

4. Determining $g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right)$namelymatrixwhich elementscontainingthe first derivation of $\underset{\sim}{\boldsymbol{\theta}}^{(k)}$
5. Determining $S^{(k)} = -(H^{(k)}) g\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right)$
6. Doing numerical iteration by using equation
$$\underset{\sim}{\boldsymbol{\theta}}^{(k+1)} = \underset{\sim}{\boldsymbol{\theta}}^{(k)} + \alpha^{(k)} S^{(k)}$$
7. Calculating $\Delta\left(\underset{\sim}{\boldsymbol{\theta}}^{(k)}\right) = \underset{\sim}{\boldsymbol{\theta}}^{(k+1)} - \underset{\sim}{\boldsymbol{\theta}}^{(k)}$
8. Back to the process number 2 up to the process number 7

Iteration is started from k = 1 and finished if $|\underset{\sim}{\boldsymbol{\theta}}^{(k+1)} - \underset{\sim}{\boldsymbol{\theta}}^{(k)}| \le e$ with e is very small value.

***Abstract*—** In the present years, climate change due to global warming, resulting in the change of seasons in Indonesia is high variability and unpredictable. Many methods that can be used to predict rainfall pattern, such as parametric regression and ARIMA. However, the model obtained through parametrics statistical approach only concerned to information of samples, therefore, it is poor to interpret the parameters of the rainfall pattern. This study proposes a bayesian nonparametric regression with Gaussian Regression Process approach for rainfall forecasting in the City of Makassar, Indonesia. Based on the value of Root Mean Square Error Prediction (RMSEP), the best covariance function that can be used to forecast is quadratic exponential.

Keywords: *quadratic exponential, rainfall forecasting, regression gaussian process, RMSEP*

I. INTRODUCTION

In the latitude and longitude, the characteristics of equatorial and monsoonal circulations in Indonesia are very different. These natural conditions resulting the rainfall in Indonesia are very unstable, complex, and have high variability. This climate change, due to global warming, also have resulted irregular change of seasons in various regions in Indonesia including the city of Makassar. This natural phenomenon causes that the currently rainfall is very difficult to predict accurately with traditional forecasting methods. Even in climatology, rainfall in Indonesia has become one of the most difficult factor to be predicted accurately.

Along with the development of modern technology, technology of rainfall forecasting has also developed rapidly, ranging from deterministic approach to the stochastic approach (Sutikno et al, 2010). The deterministic approach conducts through an analysis based on physical laws expressed in mathematical forms by using the classical statistics approaches such as (ARIMA), Fourier analysis, analysis of Kalman Filter and other methods. These forecasting methods are widely used to identify the relationship between rainfall and temperature, air pressure, wind velocity, air humidity, and solar radiation intensity (Pramudia *et al*, 2008).

Besides those approaches, some researchers concerning to climate and weather have also developed a model of rainfall prediction based on nonparametric models and based on neural networks (Estiningtyas and Kharmila 2008, Subarna 2009, Warsito and Sri, 2007). Nevertheless, the parameter estimations of model and their inferences only concern to the information from the samples obtained and ignore the prior information from researchers or field workers. According to Casella and Berger (2002), this classical approach has drawbacks in term of interpretation of the confidence interval of a parameter model. The significance of the confidence interval of a model parameter can not be based on the real level setting up before building the model.

To overcome the problem, a predictive model that can be used is Nonparametric Bayesian approach i.e. Gaussian Process Regression (GPR). The advantage of nonparametric models lies in the flexibility form of the model, in particular there are no assumptions on the parametric form (Eubank, 1999; Takezawa, 2006). Bayesian models can accommodate the researchers' prior information. Prior information is usually quantified into distribution form the parameters or the functions (Box and George, 1973).

Some researchers had used the Gaussian process regression approach to develop a model from the cases faced. Williams and Rassmusen, *et al* (2006) used the Gaussian process regression to obtain a model on the robot arm motions. In addition, Chen, *et al* (2007) used the Gaussian process regression to develop a calibration model on the spectroscopic data. Therefore, this study proposes the use of Gaussian processes regression to forecast the rainfall in the city of Makassar, Indonesia. The results of this study are expected to be able to generate a good estimation value of Gaussian Process Regression model parameter so that it produces an accurate rainfall forecasting.

II. MATERIAL AND METHOD

This study uses data of 120 observations obtained each month for last 10 years, from January 2006 to December 2015. The data are obtained from Indonesian Agency for Meteorology, Climatology, and Geophysics of province of South Sulawesi. The data used consist of one dependent variable that is the amount of rainfall (Y), and four independent variables namely; air humidity (X1), air temperature (X2), air pressure (X3), and wind velocity (X4).

The definitions of each variable used in this forecasting include; (1) rainfall is defined as the amount of water that falls on the flat land surface on certain period measured in height unit (mm) none of evaporation over horizontal surface, runoff and infiltration, (2) air humidity is the amount of water vapor content or water vapor concentration in the air measured in percentage (%), (3) air temperature is the level or degree of heat from the activity of molecules in the atmosphere or the size of kinetic energy average from the movement of molecules in the atmosphere measured in Celsius unit (^{0}C), (4) the air pressure is the pressure appeared by weight of air layer or pressure working to move air mass in each certain area unit measured in millibar (mb), and (5) wind velocity is the speed of air moving horizontally at a height of two meters above the ground measured in knot.

In analyzing the data, researcher conducts several procedure stages: the first, identify distribution patterns of Gaussian of variables used in the study, the second, make Gaussian process regression model with a review and an assignment of covariance function that will be used, the third, validate the result model of stage 2 with the criteria of Root Mean Square Error Prediction (RMSEP), and the fourth, make a prediction of the amount of monthly rainfall in 2016.

III. RESEARCH RESULTS

A. Graphic Desciption of Each Variable

Figure 1 is a graph of the dynamics of monthly rainfall from 2006 to 2015. One millimeter of rainfall means that one square meter area on the flat land accommodates as high as one millimeter of water or as much as one liter of water. Rainfall intensities are the amount of rainfall in certain time period.

Big intensity means heavy rain and this condition is very dangerous because the impact can cause flood, landslide, and drawback effect to the plants. Short-term rainfall is stated in per hour intensity called as rainfall intensity (mm/hr). The rainfall intensity average is in ½ hour. The amount of rainfall intensities are different due to rainfall durations or occurrence frequencies. Varieties of time distribution of a rainfall records can give signs of the increasing or decreasing of tendency. For the monthly rainfall occurring based on the graph, there is no repeated frequency in a year, so that it does not make a seasonal distribution. It shows that the diversity of the amount of annual rainfall is quite high. In addition, standard deviation reaches 273.1243 mm. The highest monthly amount of rainfall occurs in January of 2013 reaching 982 mm.

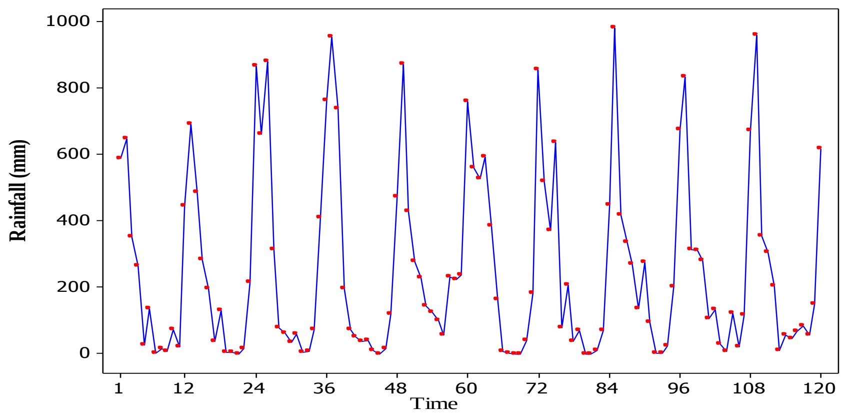

FIGURE 1. GRAPH OF THE MONTHLY RAINFALL IN THE CITY OF MAKASSAR IN 2006-2015

Furthermore, the dynamics of air humidity are presented in Fig. 2., which is the graph of the dynamics of air humidity are from 2006 to 2015. It can be seen that the air humidity each month at the early year tends to be high, while on August and September tend to decrease. The increasing and decreasing of air humidity is relatively low because the city of Makassar is in the equatorial area having tropics climate. Generally, the annual air humidity is in the range 67% to 97%. It states that the tendency of the temperature is above of the temperature average i.e. 79%.

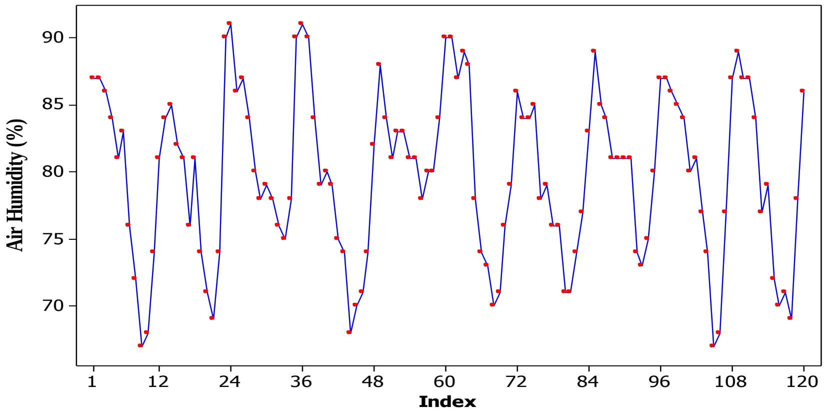

FIGURE 2. GRAPH OF THE AIR HUMIDITY IN THE CITY OF MAKASSAR IN 2006-2015

The dynamics of the air temperature average from 2006 to 2015 is revealed in Fig. 3. It shows that the annual air temperature average is erratic each month, but the annual air temperature average is generally in the range of 26.3 ^{0}C to 29 .4 ^{0}C. It states that the tendency of the temperature is above the average i.e. 27.78 ^{0}C.

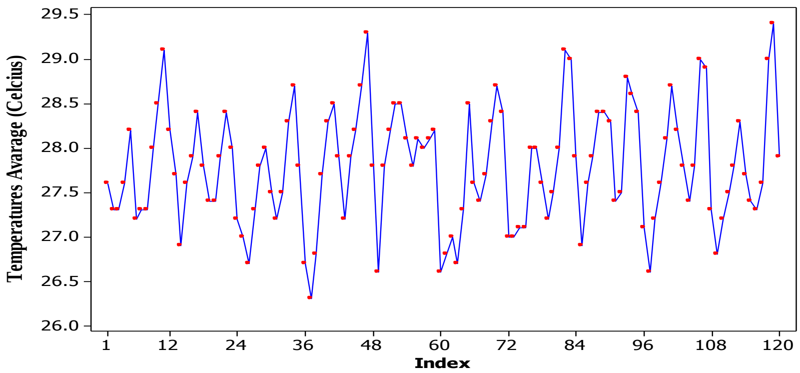

FIGURE 3. GRAPH OF THE AIR TEMPERATURE AVERAGE IN THE CITY OF MAKASSAR IN 2006-2015

The dynamic of air pressure from 2006 to 2015 is shown in Fig. 4. It shows that the dynamics of air pressure is in addictive pattern. The kinds of data has increased every year from the early 2012, but the annual air pressures are generally in the range of 1008 mb to 1013 mb. It reveals that the tendency of air pressure is above the air pressure average reaching 1010.72 mb.

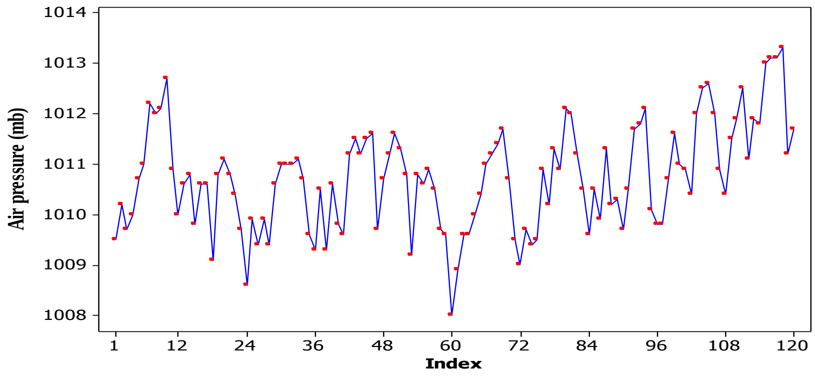

FIGURE 4. GRAPH OF THE AIR PRESSURE IN THE CITY OF MAKASSAR IN 2006-2015

Figure 6 is a graph of the dynamics of the wind velocity from 2006 to 2015. The dynamics of wind velocity tends to be almost the same from 2011 to 2015, unless the early 2014 the wind velocity is increasing. But the annual wind velocity are generally in the range from 2 knots to 7 knots. It shows that the tendency of the wind velocity is above the average air pressure i.e. 4.5 knots.

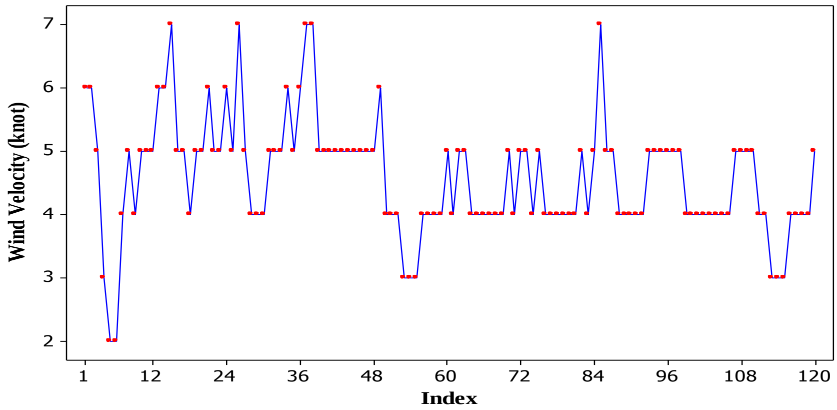

FIGURE 5. GRAPH OF THE WIND VELOCITY IN THE CITY OF MAKASSAR IN 2006-2015

B. Selection of Covariance Function

A crucial aspect of modeling Gaussian process regression is selection of covariance function. This study uses a Quadratic Exponential covariance function. Hyper-parameter values are estimated by using marginal maximum likelihood method. Table 1 shows the estimated value of the hyper-parameters of covariance function.

The covariance functions examined in this study are: (1) the function of Quadratic Exponential Covariance with distance measurements of Automatic Relevance Determination (QE-ARD), (2) the Linear covariance function with the Automatic Relevance Determination parameters (Linear-ARD), (3) the Linear covariance function with single hyper-parameter (Linear-1), and (4) Quadratic Exponential covariance function with the Isotropic distance measurement (QE-Iso).

The covariance function is conducted with concerning to the value resulted on RMSEP. After the covariance functions above are attempted to be used in the Gaussian process regression modeling, the results are shown at Table 1. It can be concluded that the covariance function, which is relevant to smallest value RMSEP, is obtained when the Gaussian process regression model uses quadratic exponential covariance function (QE-ARD), which is 137.0867. Furthermore, the covariance function will be used to predict the amount of rainfall in 2016.

TABEL 1. ESTIMATION VALUE OF HYPER-PARAMETER OF COVARIANCE FUNCTION AND RMSEP

Covariance Function	Hyper-parameter	Parameter Estimation	RMSEP
Quadratic exponential (QE- ARD)	Length scale 1 Length variance 2 Signal variance Error variance	11.285 10.185 8074.285 16034.730	137.087
Linear ARD	Bias parameter Controller 1 Bias parameter Controller 2 Error variance	10.215 10.305 20798.480	142.357
Linear-1	Bias parameter Controller Error variance	10.225 20798.48	142.327
quadratic exponential-Iso	Length scale Signal variance Error variance	8981.035 11.445 16227.670	139.857

C. Rainfall Forecasting in 2016

Before performing a prediction of the amount of monthly rainfall during 2016, the first stage is making predictions of the air humidity, the air temperature average, the air pressure, and the wind velocity during 12 months in 2016. In this case, the method used is the moving average with the period 3. The result of the prediction is shown at Table 2.

The prediction about air pressure is revealed at Table 2, the highest values is on September and October in 2016 with 1011.6 mb and the lowest value is in February 2016 reaching 1009.1 mb, the highest monthly temperature average is 28.7 ^{0}C falling in September 2016 and the lowest temperature average is in October 2016 with 26.6 ^{0}C. Based on the prediction, the highest value of air humidity is in August 2016 with 91% and the lowest value -which reached 71%- is in October 2016, while the highest value of the wind velocity based on the prediction is in May 2016 reaching 7 knots and the lowest value is in January 2016 reaching 2 knots.

TABEL 2. ESTIMATION VALUE OF HYPER-PARAMETER OF COVARIANCE FUNCTION AND RMSEP

Month	Air humidity (%)	Temperature average (^{0}C)	Air pressure (mb)	Wind velocity (knot)
January	83	27.2	1011.0	2
February	81	27.8	1009.1	4
March	90	28.0	1009.7	5
April	86	27.0	1009.9	5
May	87	26.7	1009.4	7
June	78	27.2	1011.0	5
July	75	28.3	1011.1	5
August	91	26.7	1009.3	6
September	79	27.7	1010.6	5
October	71	28.7	1011.6	5
November	88	26.6	1011.2	6
December	83	28.5	1009.2	3

The prediction results of air pressure, temperature average, humidity and wind velocity in 2016 will be the input for the interest amount of rainfall prediction in 2016 by using a Gaussian process regression model. Prediction of rainfall for 12 months using Gaussian process regression model shows at Table 3. Table 3 shows that the highest amount of rainfall prediction on the February reaching 787.2 mm with diversity 881 mm and the lowest in July 2016 reaching 38.3 mm with diversity 6 mm.

TABEL 3. ESTIMATION VALUE OF HYPER-PARAMETER OF COVARIANCE FUNCTION AND RMSEP

Month	Rainfall	Standard deviation
January	626.2	137
February	787.2	881
March	110.4	251
April	455.9	662
May	287.2	130
June	62.0	35
July	38.3	6

August	747.7	764
September	151.8	197
October	39.6	16
November	700.6	873
December	544.5	114

IV. DECISSION

Nowadays, the rainfall forecasting has also developed rapidly beginning from the deterministic approach to the stochastic approach. Gaussian process regression is one of methods that can be used to do that. This method is classified in category of non-parametric Bayesian regression model where the model specification connecting between dependent variable and independent variables is not needed to be set in advance. The data are allowed to "speak to themselves" to form the relevant structure models. Gaussian process regression using stochastic approach assumes that the amount of rainfall is random. Based on the value of Root Mean Square Error Prediction (RMSEP), the best covariance function which can be used to predict is Quadratic Exponential Automatic Relevance Determination parameters (QE-ARD) with RMSEP i.e. 137.0867. The prediction of the highest amount of rainfall is on February reaching 787.2 mm with 881 mm and the lowest amount of rainfall is in July 2016 i.e. 38.3 mm with 6 mm. Compared to other classical methods that are not able to accommodate the initial information and not to impose the modeling, Gaussian process regression approach is relatively good to be used.

Least Squares Estimator for β in Multiple Regression Estimation

Tubagus Pamungkas
Pend Matematika Unrika Batam
Batam, Indonesia
tubagus@unrika.ac.id

***Abstract*—**Regression analysis has been developed to study the pattern and measure the statistical relationship between two or more variables . Mechanical analysis that attempts to explain the relations between two or more variables or more specifically the relationship between variables containing causation is called regression analysis . The procedure is based on the analysis of joint probability distribution variables. If this relationship can be expressed in a mathematical equation , it can be used in everyday purposes , for example to make predictions , fortune telling , and so on

Overall regression test with paramater (parametric regression) and regression without parameter (semiparametric regression) in advance will be discussed for parametric regression parameters $\boldsymbol{\beta_1}$, $\boldsymbol{\beta_2}$, …, $\boldsymbol{\beta_{m-1}}$, $\boldsymbol{\beta_m}$ which is an element β in a model y = Xβ + ε. in this case will assume that y distribution Nn (Xβ, σ2I), where X notated n x (m+1) from rank m+1 < n.

Least Square approach to estimation of the β in the fixed model, for the parameter $\beta_0, \beta_1, \beta_2, \ldots \ldots \beta_m$, estimators that minimize the sum of squares of deviations of the n observed y from their predicted values $\hat{y}$.

Keywords: *regression, estimator, least square.*

I. INTRODUCTION

In everyday life there are things that can be solved using mathematics, statistics is one way to collect data, process, analyze and conclude. Regression analysis is a technique to look at the correlation between two or more variables and then estimation become a model that can be an equation that can connect the dependent variable of the independent variable. Many paper non-parametric regression estimation for efficiency in production on the independent variables in certain procedures to explain the factors that may affect the performance of the dependent variable. The regression model that handles these situations requires a set of equations (one single equation alone is not enough) that need to be solved simultaneously and this model is known as econometric models. In addition, conventional approaches to inference used in this paper is invalid because an elaborate serial correlation, unknown among the estimated efficiencies. Authors first describe a decent data for models like this.

The mathematical equations that allow to forecast the values of a dependent variable of one or more independent variables called the regression equation. The term is derived from the results of observations made Sir Francis Galton (1822 - 1911) that compares the height of a boy with his father's height. Galton states that the height of the boys from the father high on several generations later tended to "regressed" close to the average population.

Watson (1937) uses a regression of leaf area to estimate the average extent in a factory. The procedure is to weigh the whole leaves of the plant. For a small sample of the leaves, broad and weight of each leaf has been set. On average regression on the weight of the leaves, the core of the application is that the weight of the leaves can be found quickly but the determination is time consuming.

II. DISCUSSION

The muptiple linear regression model can be expressed as $y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots . + \beta_m x_m + \mathcal{E}$ The$\beta_0, \beta_1, \beta_2, \ldots . \beta_m$ can be estimated by the least square approximation as long as the model is linear in the $\beta_0, \beta_1, \beta_2, \ldots . \beta_m$

We have n observation, with this equation

$$y_1 = \beta_0 + \beta_1 x_{11} + \beta_2 x_{12} + \beta_3 x_{13} + \cdots + \beta_m x_{1m} + \varepsilon_1$$

$$y_2 = \beta_0 + \beta_1 x_{21} + \beta_2 x_{22} + \beta_3 x_{23} + \cdots + \beta_m x_{2m} + \varepsilon_2$$

$$y_3 = \beta_0 + \beta_1 x_{31} + \beta_2 x_{32} + \beta_3 x_{33} + \cdots + \beta_m x_{3m} + \varepsilon_3$$

$$\vdots$$

$$y_{n-1} = \beta_0 + \beta_1 x_{(n-1)1} + \beta_2 x_{(n-1)2} + \beta_3 x_{(n-1)3} + \cdots + \beta_m x_{(n-1)m} + \varepsilon_{(n-1)})$$

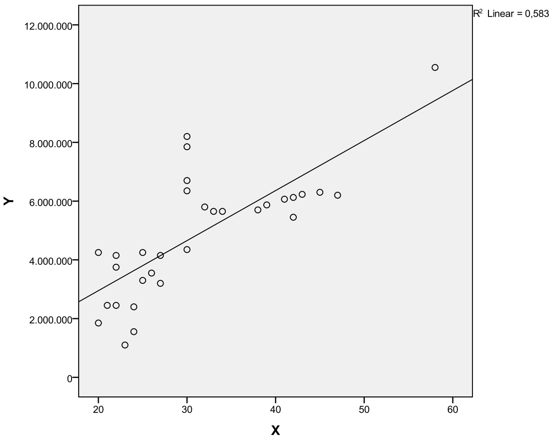
$$y_n = \beta_0 + \beta_1 x_{n1} + \beta_2 x_{n2} + \beta_3 x_{n3} + \cdots + \beta_m x_{nm} + \varepsilon_n$$

We can show thats equation in matrix formula $y = X\beta + \varepsilon$

With $y = \begin{pmatrix} y_1 \\ y_2 \\ y_3 \\ \vdots \\ y_{n-1} \\ y_n \end{pmatrix}$, $\mathcal{E} = \begin{pmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \varepsilon_3 \\ \vdots \\ \varepsilon_{n-1} \\ \varepsilon_n \end{pmatrix}$and than $X = \begin{pmatrix} 1 & x_{11} & x_{12} & \cdots & x_{1m} \\ 1 & x_{21} & x_{22} & \cdots & x_{2m} \\ 1 & x_{31} & x_{32} & \cdots & x_{3m} \\ \vdots & \vdots & \vdots & \cdots & \vdots \\ 1 & x_{n1} & x_{n2} & \cdots & x_{nm} \end{pmatrix}$

Estimator of β

For the all of parameter $\beta_0, \beta_1, \beta_2, \ldots . \beta_m$ and for minimize the sum of square of deviations in an observation we can predict value of $\hat{y}$ with $\hat{\beta}_0, \hat{\beta}_1, \hat{\beta}_2, \ldots ., \hat{\beta}_m$ so we can use equation $y_1 = \beta_0 + \beta_1 x_{11} + \beta_2 x_{12} + \beta_3 x_{13} + \cdots + \beta_m x_{1m} + \varepsilon_1$ until $y_n = \beta_0 + \beta_1 x_{n1} + \beta_2 x_{n2} + \beta_3 x_{n3} + \cdots + \beta_m x_{nm} + \varepsilon_n$ with the equation $\hat{y}_i = \hat{\beta}_0 + \hat{\beta}_1 x_{i1} + \hat{\beta}_2 x_{i2} + \hat{\beta}_3 x_{i3} + \cdots + \hat{\beta}_m x_{im}$



the linear line $\hat{y}$ shows the distribution of the dots indicate y, so it can be seen that $\hat{y} = \varepsilon + y$ in other words $\varepsilon = \hat{y} - y$ withdrawal procedure known regression line is the least squares method (ordinary least squares) or better known with the term OLS. This method choose a regression line to make the sum of squared vertical distances of the points through which the straight line as small as possible, whereby if the multiple linear regression model of the population is $y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots . + \beta_m x_m + \mathcal{E}$ where as the estimation model of multiple linear regression is $\hat{y}_i = \hat{\beta}_0 + \hat{\beta}_1 x_{i1} + \hat{\beta}_2 x_{i2} + \hat{\beta}_3 x_{i3} + \cdots + \hat{\beta}_m x_{im}$ so meaning OLS estimates on multiple linear regression there are:

Population regression equation : $y = X\hat{\beta} + \varepsilon$

Residual (estimate of random error) : $\varepsilon = y - X\hat{\beta}$

Sum of Squares Error (SSE) : $\hat{\varepsilon}'\hat{\varepsilon} = (y - X\hat{\beta})'(y - X\hat{\beta})$

$= y'y - 2\hat{\beta}'y + \hat{\beta}'X'X\hat{\beta}$

minimize SSE : $\frac{\partial(\hat{\varepsilon}'\hat{\varepsilon})}{\partial\hat{\beta}} = -2X'y + 2X'X\hat{\beta} = 0$

Estimator OLS : $\hat{\beta} = (X'X)^{-1}X'y$

Least square estimation for $\hat{\beta}$

From estimation OLS $\hat{\beta} = (X'X)^{-1}X'y$ if $E(y) = X\beta$ then $\hat{\beta}$ is an unbiased estimator for β so we can show that $E(\hat{\beta}) = E((X'X)^{-1}X'y)$

$E(\hat{\beta}) = (X'X)^{-1}X'E(y)$=β

III. CONCLUSION

Linear regression estimates were made to improve the accuracy by using additional variables that correlated with. When y_i the relationship between x_i and y_i tested, it was found that although the relationship may be a linear approach, the line is not via the point of origin. These results suggest an estimate based on a linear regression of the y_i from x_i better than the ratio of two variables.

Estimated regression is consistent, in simple terms when the sample consists of all units of the population $\bar{x} = \bar{X}$ and reduce the regression estimates $\bar{Y}$. As will be shown, in general regression estimates are biased, but the ratio of the bias is to the standard error becomes smaller when large samples.

With an appropriate choose of β , regression estimates included as special cases on average per unit and the estimated ratio, when β taken equal to zero, y_i reducing $\hat{y}$ but if $\beta = \frac{\bar{y}}{\bar{x}}$, so $\hat{y} = \bar{y} + \beta(\bar{X} - \bar{x}) = \bar{y} + \frac{\bar{y}}{\bar{x}}(\bar{X} - \bar{x}) = \hat{\bar{Y}}$

Email: yanita3010@gmail.com

Abstract—This article discuss about presentation group $\langle a, b; a^p, b^q, aba^{-1}b^{-1}\rangle$ and $\langle t; t^{pq}\rangle$. It is shown that these presentations are isomorphism and there is process to compute generator of second homotopy module from $\pi_2(\langle a, b; a^p, b^q, aba^{-1}b^{-1}\rangle)$ to $\pi_2(\langle t; t^{pq}\rangle)$. This computation using Tietze transformation and operation on picture.

Keywords: *presentation group, second homotopy module, generator, Tietze transformation*

I. INTRODUCTION

Group are very often described as quotient group of free group: $G = F/N$. If F is free with base $\boldsymbol{x}$ and N is normal closure in F of a set $\boldsymbol{r}$, we say that the pair $\langle \boldsymbol{x}; \boldsymbol{r}\rangle$ is a *presentation*,. Set $\boldsymbol{x}$ is *defining generator* of G and set $\boldsymbol{r}$ is *defining relations*. The element of $\boldsymbol{r}$ will be called relator.
A presentation $\langle \boldsymbol{x}; \boldsymbol{r}\rangle$ is finitely generated if $\boldsymbol{x}$ is finite, and is finitely related if $\boldsymbol{r}$ is finite. A presentation $\langle \boldsymbol{x}; \boldsymbol{r}\rangle$ is finite if both of $\boldsymbol{x}$ and $\boldsymbol{r}$ are finite, in this case $\langle \boldsymbol{x}; \boldsymbol{r}\rangle$ is finitely presented. There are some alterations one can make to a presentation which result in presentations of a group isomorphic to the original. These are called Tietze transformations. Let $\mathcal{P} = \langle \boldsymbol{x}; \boldsymbol{r}\rangle$ so we have *first fundamental group* $(\pi_1(\mathcal{P}))$ and *second homotopy module* $((\pi_2(\mathcal{P}))$ of presentation group. Therefore this article discuss about second homotopy module. The element of second homotopy module is equivalence class of spherical picture.

II. PRELIMINARIES

We review some definitions and results that we will use to solve the main result of this article.

Definition 2.1 (Definition of Tietze Transformation) ([3], [5]) *Let* $\mathcal{P}_1 = \langle \boldsymbol{x}\,; \boldsymbol{r}\rangle$ *and* $\mathcal{P}_2 = \langle \boldsymbol{y}\,; \boldsymbol{s}\rangle$ *be two presentations of the group* G.

(*T1*) *If the word S is derivable from* $\boldsymbol{r}$, *then add S to the list of relators;* $\langle \boldsymbol{x}\,; \boldsymbol{r}\rangle \to \langle \boldsymbol{x}\,; S, \boldsymbol{r}\rangle$

(*T2*) *If the word S is derivable from* $\boldsymbol{r}$, *remove S from the list relators;* $\langle \boldsymbol{x}\,; S, \boldsymbol{r}\rangle \to \langle \boldsymbol{x}\,; \boldsymbol{r}\rangle$

(*T3*) *If R is word in the* $\boldsymbol{x}$, *and y is some symbol not in the generating set, add y to the generating set and add word* $y^{-1}R \in \boldsymbol{r}$, $y \in \boldsymbol{x}$ *to the relator set.*

(*T4*) *If there is a relator of the form* $y^{-1}R \in \boldsymbol{r}$, $y \in \boldsymbol{x}$ *with y not appearing in R, delete this relator and delete y from the generating set, replacing all order occurences of y in the relator words with* R.

Theorem 2.2 ([5]) *Suppose that the groups presented by the two presentations* $\langle \boldsymbol{x}; \boldsymbol{r}\rangle$ *and* $\langle \boldsymbol{y}; \boldsymbol{s}\rangle$ *are isomorphic. Then there is a sequence of Tietze transformations leading from one of these to the other. If these presentations are both finite the sequence can be taken to be a finite number of single step.*

Definition 2.3 ([6]) *A picture* $\mathbb{P}$ *over* $\mathcal{P}$ *is a geometric configuration consisting of of the following:*

a. *A disc D^2 with basepoint O on ∂D^2.*
b. *Disjoint discs $\Delta_1, \Delta_2, \dots, \Delta_n$ in the interior of D^2. Each Δ_i has a basepoint O_i on $\partial\Delta_i$.*
c. *A finite number of disjoint arcs $\alpha_1, \alpha_2, \dots, \alpha_m$ where each arc lies in the closure of $D^2 - \bigcup_{i=1}^{n}\Delta_i$ and is either simple closed curve having trivial intersection with $\partial D^2 \cup (\bigcup_{i=1}^{n}\partial\Delta_i)$, or is a simple non-closed curve which join two points of $\partial D^2 \cup (\bigcup_{i=1}^{n}\partial\Delta_i)$, neither point being a basepoint. Each arc has a normal orientation, indicated by a short arrow meeting with the arc transversely and is labelled by an element of $\boldsymbol{x} \cup \boldsymbol{x}^{-1}$.*
d. If we travel around $\partial\Delta_i$ once in clockwise direction starting from O_i and read off the labels on arcs encountered (if we cross an arc, labelled x say, in the direction of its normal orientation, then we read x^{-1}), then we obtain a word which belongs to $\boldsymbol{r} \cup \boldsymbol{r}^{-1}$. We call this word the label of Δ_i.

Definition 2.4 ([6]) *A picture $\mathbb{P}$ over $\mathcal{P} = \langle \boldsymbol{x}; \boldsymbol{r}\rangle$ is a spherical picture if all arcs in $\mathbb{P}$ do not touch the boundary disc.*

Two spherical pictures $\mathbb{P}_1$ and $\mathbb{P}_2$ are said to be *equivalent* if either: (a) both are spherical and one can be transformed to the other by a finite number of operation deletion and insertion floating circle, deletion and insertion folding pair and bridge move; or (b) both are not spherical and one can be transformed to the other by a finite number of operation deletion and insertion floating circle, deletion and insertion semicircle, deletion and insertion folding pair and bridge move. Base on [1], A set $\boldsymbol{P}$ of spherical picture over $\mathcal{P} = \langle \boldsymbol{x}; \boldsymbol{r}\rangle$ is called a set of generator $\pi_2(\mathcal{P})$ if $\{[\mathrm{P}]:\mathrm{P} \in \boldsymbol{P}\}$ generate $\mathbb{Z}G$ $-$module. Base on [2], set generator $\boldsymbol{P}$ is generator iff each spherical picture over $\mathbb{P}$ can be transformated to empty picture by using operation on picture.

III. THE MAIN RESULT

We consider presentation group $\langle a, b; a^p, b^q, aba^{-1}b^{-1}\rangle$ and $\langle t; t^{pq}\rangle$. It is shown that these presentation are isomorphic using Tiestze transformation.

Note that, if p and q nonzero integer, there are integer m and n such that $mp + nq = \gcd(p, q)$. Since p and q are prime relative, so $\gcd(p, q) = 1 = mp + \_nq$..

Tietze transformation of $\langle a, b; a^p, b^q, aba^{-1}b^{-1}\rangle$ to $\langle t; t^{pq}\rangle$.

$\langle a, b; a^p, b^q, aba^{-1}b^{-1}\rangle$

$\xrightarrow{T3} \langle a, b, t; a^p, b^q, aba^{-1}b^{-1}, t = a^n b^m\rangle$

Add generator t in to set of generator with relation $t = a^n b^m$.

$\xrightarrow{T1} \langle a, b, t; a^p, b^q, aba^{-1}b^{-1}, t = a^n b^m, t^{pq}\rangle$

Add t^{pq} in to set of relation, since derived from $t = a^n b^m$, $a^p = 1$, and $b^q = 1$, that is $t^{pq} = (a^n b^m)^{pq} = a^{npq} b^{mpq} = 1$.

$\xrightarrow{T1} \langle a, b, t; a^p, b^q, aba^{-1}b^{-1}, t = a^n b^m, t^{pq}, a = t^q\rangle$

Add relator $a = t^q$ since derived from :

$$\begin{aligned} t^q &= (a^n b^m)^q \\ &= a^{nq} b^{mq} \\ &= a^{nq} \text{ since } b^q = 1 \\ &= a^{1-mp} \text{ since } mp + nq = 1 \\ &= aa^{-mp} = a \text{ since } a^p = 1 \end{aligned}$$

$\xrightarrow{T1} \langle a, b, t; a^p, b^q, aba^{-1}b^{-1}, t = a^n b^m, t^{pq}, a = t^q, b = t^p\rangle$

Add relator $b = t^p$ since derived from:

$$\begin{aligned} t^p &= (a^n b^m)^p \\ &= a^{np} b^{mp} \\ &= b^{mp} \text{ since } a^p = 1 \\ &= b^{1-mq} \text{ since } mp + nq = 1 \\ &= bb^{-mq} \\ &= b \text{ since } b^q = 1 \end{aligned}$$

$\xrightarrow{T2} \langle a, b, t; a^p, b^q, t = a^n b^m, t^{pq}, a = t^q, b = t^p \rangle$

Delete $aba^{-1}b^{-1}$ from set of relations, since $a = t^q$ and $b = t^p$, so we have $1 = t^q t^p t^{-q} t^{-p} = aba^{-1}b^{-1}$.

$\xrightarrow{T2} \langle a, b, t; b^q, t = a^n b^m, t^{pq}, a = t^q, b = t^p \rangle$

Delete a^p from set of relations, since t^{pq} and $a = t^q$ so we have $a^p = (t^q)^p = t^{pq} = 1$.

$\xrightarrow{T2} \langle a, b, t; t = a^n b^m, t^{pq}, a = t^q, b = t^p \rangle$

Delete b^q from set of relations, since t^{pq} and $b = t^p$ so we have $b^q = (t^p)^q = t^{pq} = 1$.

$\xrightarrow{T2} \langle a, b, t; t^{pq}, a = t^q, b = t^p \rangle$

Delete relator $t = a^n b^m$ since derived from $a = t^q, b = t^p$ and $t^{pq} = 1$, that is :
$t = t^{mp+nq} = t^{mp} t^{nq} = a^n b^m$

$\xrightarrow{T4} \langle b, t; t^{pq}, b = t^p \rangle$

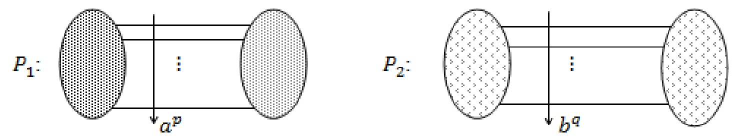
Delete generator a from set of generators

$\xrightarrow{T4} \langle t; t^{pq} \rangle$

Delete generator b from set of generators

So we have $\langle a, b; a^p, b^q, aba^{-1}b^{-1} \rangle \cong \langle t; t^{pq} \rangle$.

Base on [2] we have generators of $\pi_2(\langle a, b; a^p, b^q, aba^{-1}b^{-1} \rangle)$ are spherical picture containing discs a^p, b^q, a^p and $aba^{-1}b^{-1}$; and spherical picture containing discs b^q and disc $aba^{-1}b^{-1}$. We say that generators are P_1, P_2, P_3 dan P_4 , respectively, i. e:



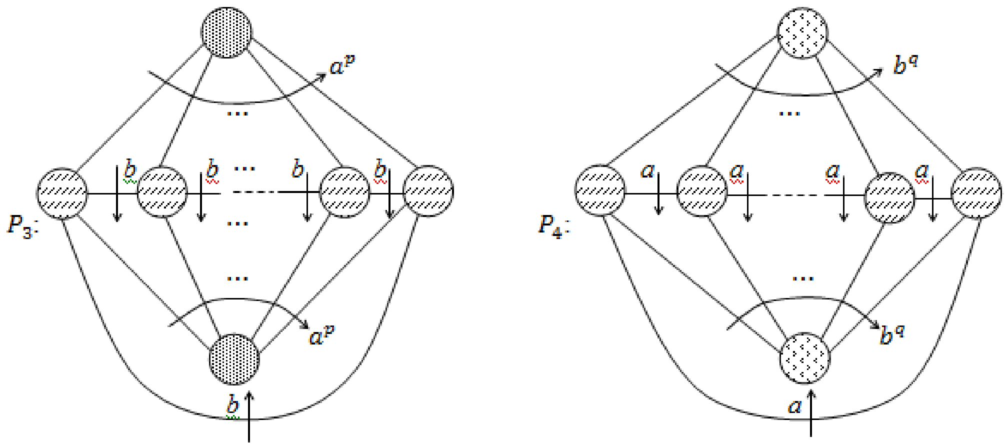


Figure 1: The generator of $\pi_2(\langle a, b; a^p, b^q, aba^{-1}b^{-1} \rangle)$

Whereas generator of $\pi_2(\langle t; t^{pq} \rangle)$ is spherical picture containing disc t^{pq}, that is

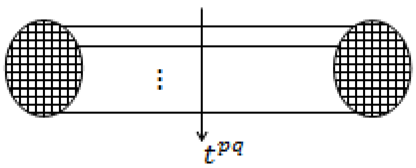

Figure 2: The generator of $\pi_2(\langle t; t^{pq} \rangle)$

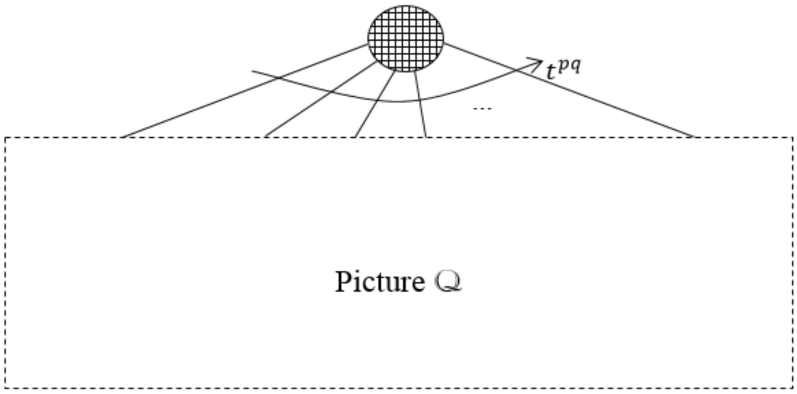
Furthermore, we use Theorem 1, Theorem 2, Corrolari 1 and Corrolari 2 on [7] to compute generator of second homotopy module of each presentation, i.e:

ISBN 978-602-74529-0-9

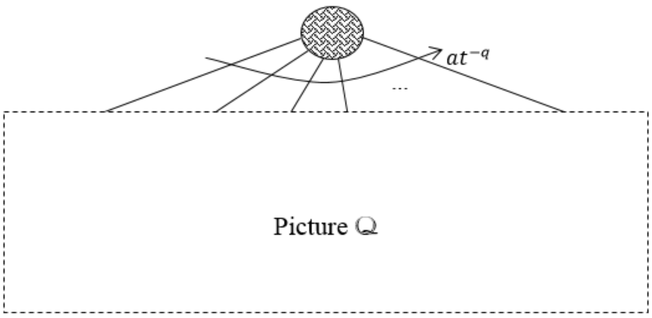
1. $\xrightarrow{T3} \langle a, b, t; a^p, b^q, aba^{-1}b^{-1}, t = a^n b^m \rangle$
   Generators of $\pi_2(\langle a, b, t; a^p, b^q, aba^{-1}b^{-1}, t = a^n b^m \rangle)$ equal to generator of $\pi_2(\langle a, b; a^p, b^q, aba^{-1}b^{-1} \rangle)$, that is, P_1, P_2, P_3 dan P_4.

2. $\xrightarrow{T1} \langle a, b, t; a^p, b^q, aba^{-1}b^{-1}, t = a^n b^m, t^{pq} \rangle$
   Generators of $\pi_2(\langle a, b, t; a^p, b^q, aba^{-1}b^{-1}, t = a^n b^m, t^{pq} \rangle)$ are P_1, P_2, P_3, P_4 and P_5 , which P_5 is generator containing disc t^{pq},



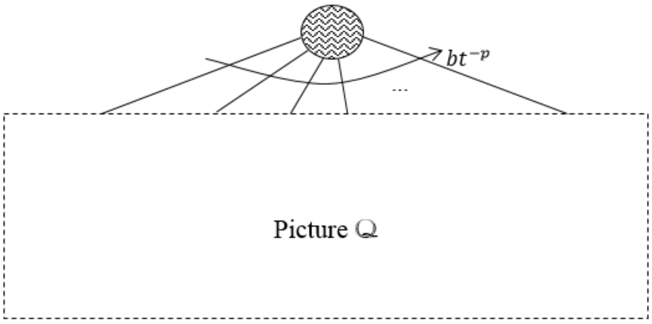
and $\mathbb{Q}$ is picture containing discs $a^n b^m$, a^p, b^p and $aba^{-1}b^{-1}$.

3. $\xrightarrow{T1} \langle a, b, t; a^p, b^q, aba^{-1}b^{-1}, t = a^n b^m, t^{pq}, a = t^q \rangle$
   Generators of $\pi_2(\langle a, b, t; a^p, b^q, aba^{-1}b^{-1}, t = a^n b^m, t^{pq}, a = t^q \rangle)$ are P_1, P_2, P_3, P_4, P_5 dan P_6, which P_6 is generator containing disc at^{-q}, that is



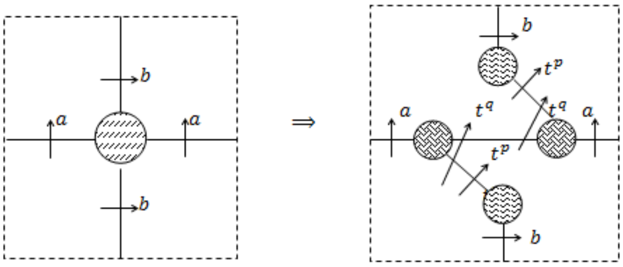
and $\mathbb{Q}$ is picture containing discs $a^n b^m$, b^p and $aba^{-1}b^{-1}$.

4. $\xrightarrow{T1} \langle a, b, t; a^p, b^q, aba^{-1}b^{-1}, t = a^n b^m, t^{pq}, a = t^q, b = t^p \rangle$
   Generators of $\pi_2(\langle a, b, t; a^p, b^q, aba^{-1}b^{-1}, t = a^n b^m, t^{pq}, a = t^q, b = t^p \rangle)$ are $P_1, P_2, P_3, P_4, P_5, P_6$ and P_7, which P_7 is generator containing disc $b = t^p$,

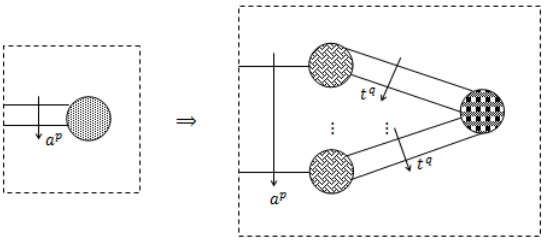


and $\mathbb{Q}$ is picture containing discs $a^n b^m$, a^p and $aba^{-1}b^{-1}$.

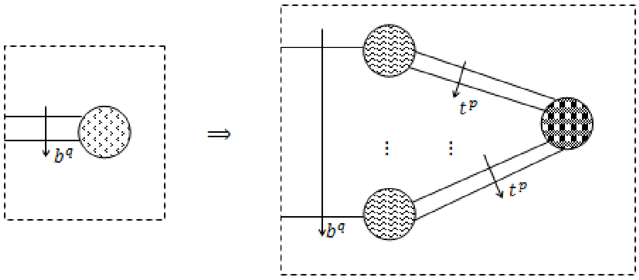
5. $\xrightarrow{T2} \langle a, b, t; a^p, b^q, t = a^n b^m, t^{pq}, a = t^q, b = t^p \rangle$
On $\pi_2(\langle a, b, t; a^p, b^q, aba^{-1}b^{-1}, t = a^n b^m, t^{pq}, a = t^q, b = t^p \rangle)$ there is a deletion disc $aba^{-1}b^{-1}$ and replace arc a be t^q and arc b be t^p. So, generators containing disc $aba^{-1}b^{-1}$ will be changed, as seen below:



6. $\xrightarrow{T2} \langle a, b, t; b^q, t = a^n b^m, t^{pq}, a = t^q, b = t^p \rangle$
On $\pi_2(\langle a, b, t; a^p, b^q, t = a^n b^m, t^{pq}, a = t^q, b = t^p \rangle)$ there are deletion of disc a^p. The generators containing disc a^p will be changed, as seen below:

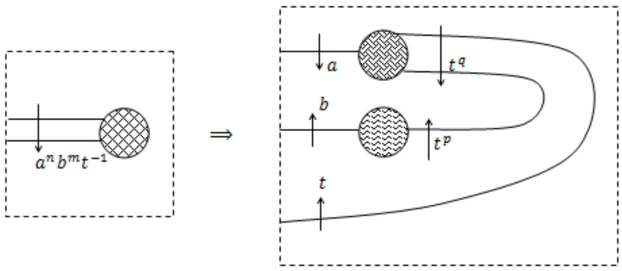


7. $\xrightarrow{T2} \langle a, b, t; t = a^n b^m, t^{pq}, a = t^q, b = t^p \rangle$
On $\pi_2(\langle a, b, t; b^q, t = a^n b^m, t^{pq}, a = t^q, b = t^p \rangle)$ there is a deletion of disc b^q The generators containing disc b^q will be changed, as seen below:



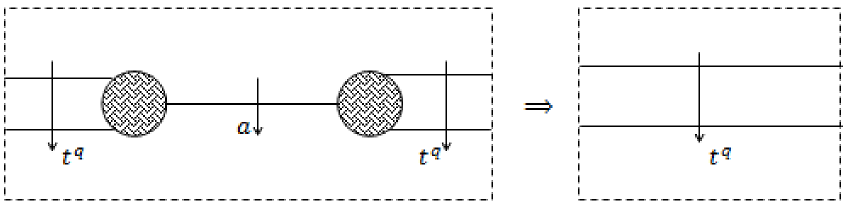
8. $\xrightarrow{T4} \langle a, b, t; t^{pq}, a = t^q, b = t^p \rangle$

On $\pi_2(\langle a, b, t; t = a^n b^m, t^{pq}, a = t^q, b = t^p \rangle)$ there is a deletion $t = a^n b^m$. The generators containing disc $t = a^n b^m$ ($t = a^n b^m \Leftrightarrow a^n b^m t^{-1}$) will be changed, as seen below:



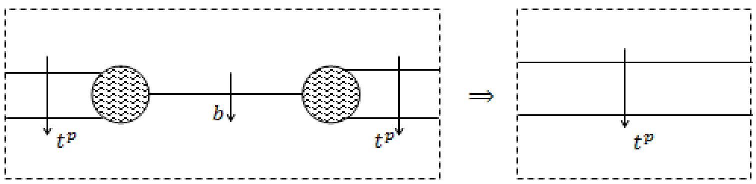
9. $\xrightarrow{T4} \langle b, t; t^{pq}, b = t^p \rangle$

On $\pi_2(\langle a, b, t; t^{pq}, a = t^q, b = t^p \rangle)$ there is deletion generator a. The generators containing disc a will be changed, as seen below:

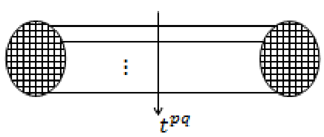


10. $\xrightarrow{T4} \langle t; t^{pq} \rangle$

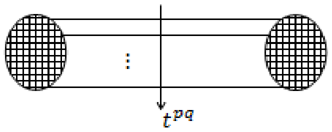
On $\pi_2(\langle b, t; t^{pq}, b = t^p \rangle)$ there is deletion generator b. The generators containing disc b will be changed, as seen below:



Finally, we have generator containing disc t^{pq}, that is:



Thus, generaotos of $\pi_2(\langle t; t^{pq} \rangle)$ is



IV. EXAMPLE

Consider group presentation $\langle a,b;a^2,b^3,aba^{-1}b^{-1}\rangle$ and $\langle t;t^{2.3}\rangle=\langle t;t^6\rangle$. Remember that 2 and 3 are relatively prime, so there are integers m and n such that $2m+3n=1$. Let $m=-1$ and $n=1$.

Tietze transformation from $\langle a,b;a^2,b^3,aba^{-1}b^{-1}\rangle$ to $\langle t;t^6\rangle$.

$\langle a,b;a^2,b^3,aba^{-1}b^{-1}\rangle$

$\xrightarrow{T3}\langle a,b,t;a^2,b^3,aba^{-1}b^{-1},t=ab^{-1}\rangle$

$\xrightarrow{T1}\langle a,b,t;a^2,b^3,aba^{-1}b^{-1},t=ab^{-1},t^6\rangle$

$\xrightarrow{T1}\langle a,b,t;a^2,b^3,aba^{-1}b^{-1},t=ab^{-1},t^6,a=t^3\rangle$

$\xrightarrow{T1}\langle a,b,t;a^2,b^3,aba^{-1}b^{-1},t=ab^{-1},t^6,a=t^3,b=t^2\rangle$

$\xrightarrow{T2}\langle a,b,t;a^2,b^3,t=ab^{-1},t^6,a=t^3,b=t^2\rangle$

$\xrightarrow{T2}\langle a,b,t;b^3,t=ab^{-1},t^6,a=t^3,b=t^2\rangle$

$\xrightarrow{T2}\langle a,b,t;t=ab^{-1},t^6,a=t^3,b=t^2\rangle$

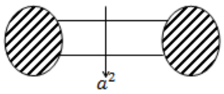
$\xrightarrow{T4}\langle a,b,t;t^6,a=t^3,b=t^2\rangle$

$\xrightarrow{T4}\langle b,t;t^6,b=t^2\rangle$

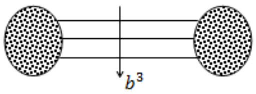
$\xrightarrow{T4}\langle t;t^6\rangle$

We have four generators of $\pi_2(\langle a,b;a^2,b^3,aba^{-1}b^{-1}\rangle)$, that is:

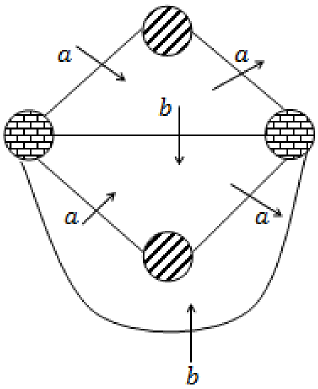
P_1:



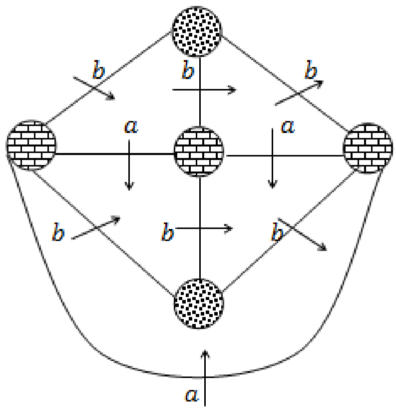
P_2:



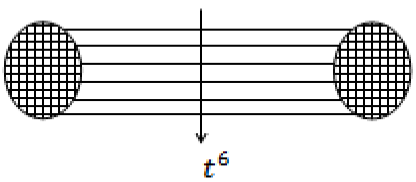
P_3:



P_4:

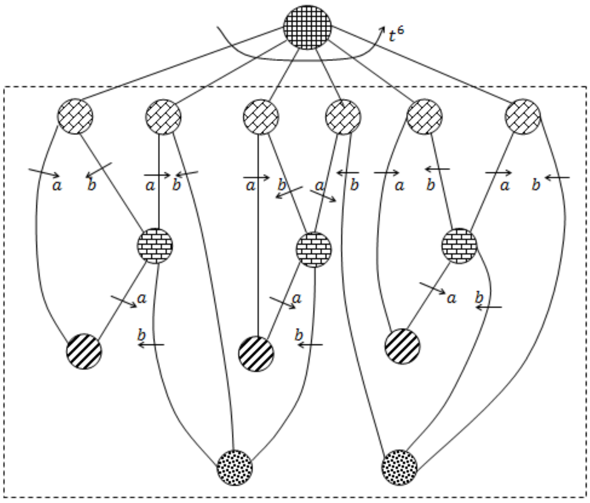


Meanwhile, generator of $\pi_2(\langle t;t^6\rangle)$ is

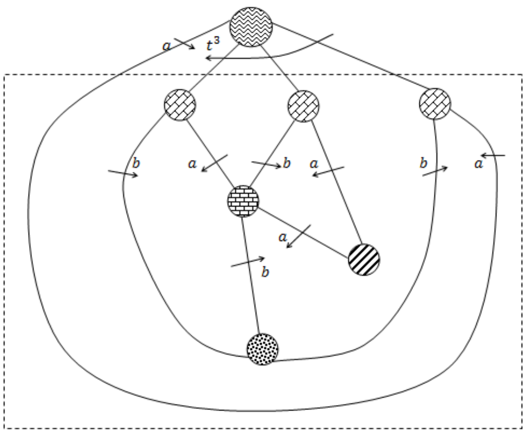


Next, will be shown the process of changing generators of $\pi_2(\langle a,b;a^2,b^3,aba^{-1}b^{-1}\rangle)$ to $\pi_2(\langle t;t^6\rangle)$:

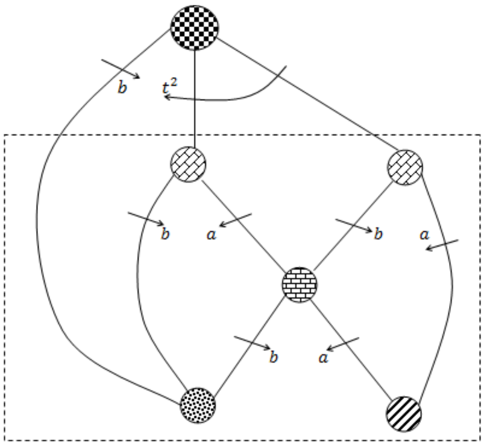
1. $\xrightarrow{T3} \langle a,b,t;a^2,b^3,aba^{-1}b^{-1},t=ab^{-1}\rangle$
   The generators of $\pi_2(\langle a,b,t;a^2,b^3,aba^{-1}b^{-1},t=ab^{-1}\rangle)$ are P_1, P_2, P_3 and P_4.
2. $\xrightarrow{T1} \langle a,b,t;a^2,b^3,aba^{-1}b^{-1},t=ab^{-1},t^6\rangle$
   The generators of $\pi_2(\langle a,b,t;a^2,b^3,aba^{-1}b^{-1},t=ab^{-1},t^6\rangle)$ are P_1, P_2, P_3, P_4 and P_5, where P_5 is



3. $\xrightarrow{T1} \langle a,b,t;a^2,b^3,aba^{-1}b^{-1},t=ab^{-1},t^6,a=t^3\rangle$
   The generators of $\pi_2(\langle a,b,t;a^2,b^3,aba^{-1}b^{-1},t=ab^{-1},t^6,a=t^3\rangle)$ are P_1, P_2, P_3, P_4, P_5 and P_6, where P_6 is

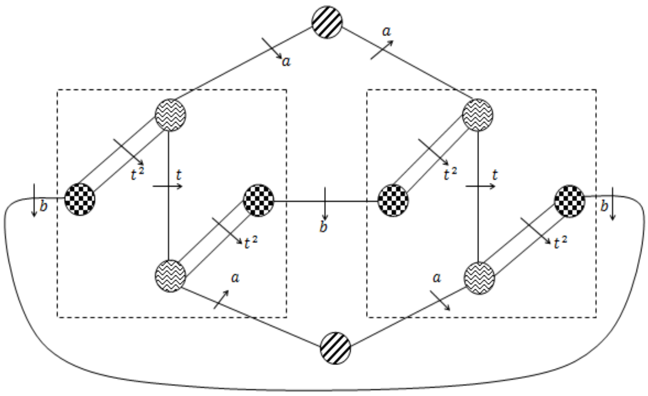


4. $\xrightarrow{T1} \langle a,b,t;a^2,b^3,aba^{-1}b^{-1},t=ab^{-1},t^6,a=t^3,b=t^2\rangle$
   The generators of $\pi_2(\langle a,b,t;a^2,b^3,aba^{-1}b^{-1},t=ab^{-1},t^6,a=t^3,b=t^2\rangle)$ are P_1, P_2, P_3, P_4, P_5, P_6 and P_7, where P_7 is



5. $\xrightarrow{T2} \langle a, b, t; a^2, b^3, t = ab^{-1}, t^6, a = t^3, b = t^2 \rangle$
Generators P_3, P_4, P_5, P_6 and P_7 containing $aba^{-1}b^{-1}$ will be changed, and each one is named $P_3{}'$, $P_4{}'$, $P_5{}'$, $P_6{}'$ and $P_7{}'$.

$P_3{}'$:



$P_4{}'$:

Literatur Study:
The Relationship of Mathematics Problem Solving and Students' Higher Order Thinking Skills

Adri Nofrianto[1], Mira Amelia Amri[2], Elfa Rafulta[3]
[1,2,3]Mathematics Education Department, STKIP YDB Lubuk Alung
adrinofrianto@gmail.com

***Abstract*—** The literature review is focusing on the use of mathematics problem solving in assessing students' higher order thinking. There is evidence that mathematics problem solving is related to critical, reflective, Metacognitive and creative as parts of higher order thinking. Theorizing from these findings, the study describes the relationship of mathematics problem solving and higher order thinking, how mathematics problem solving assesses students' higher order thinking and how mathematics problem solving might develop students higher order thinking. Findings suggest that more research is needed to gain new insight in categorizing mathematics problems that can be used in assessing and developing students' higher order thinking.
Keywords: *higher order thinkin skills, mathematics problem solving*

I. INTRODUCTION

This paper review about the use of mathematics problem solving in assessing and developing higher order thinking. The objective that gaided and motivated this review is our advocacy the use of problem solving in developing students' higher order thinking (HOT) since it is a necessary skills in the future [1]. Moreover, the opportunity to develop students' HOT skills has been shown by researches ([2], [3], [4]). Realizing the important of HOT skills, Indonesia government has conducted several efforts. The efforts are changing curriculum, teacher training and supporting research in education. Developing a learning instructions that can develop student competencies, HOT skills, becomes necessary. Pre-research that needed to be conducted is literature study. Doing a thorough analysis of literature study will provide information about theory and practices that related to development of HOT skills. This analysis can change researcher paradigm, point of view and theoretical perspectives about research area. As a result, the plan research can be guided to a new findings in HOT skills. Therefore, this literature review is conducted in order to find the relationship between HOT skills and mathematics problem solving.

The aim of this study is to review literature that related to HOT skills and mathematics problem solving in order to evaluate what is currently knowledge about how mathematics problem solving assess and develop HOT skills. The evidences are looked specifically in types of problems and reasons why problem solving is used in assessing and developing HOT skills.

II. HIGHER ORDER THINKING SKILLS

Higher order thinking has been defined by many researchers. Byrnes[5] defined higher-order thinking as a way of handling a situation that have not encountered before and is generally recognized as some combination of non-algorithmic, complex, effortful, nuanced judgments, application of multiple criteria, uncertainty about what is known and regulation. The characteristics that encounter of individuals are may vary in many ways, numbers and difficulties.

Regarding Bloom taxonomy, thinking processes that remarked as higher order thinking are synthesize, evaluate, and create. Based on this theory, many researchers defined HOT in a wide variety of definitions. The definition is summarizing as bellows:

1. King, Goodson, and Rohani [6] viewed than HOT skills are critical, logical, reflective, metacognitive and creative thinking. All of this aspects are activated when an individual encounter un familiar problems, uncertainties, questions and dilemma.
2. National Council of Teachers of Mathematics (NCTM) [7] proposed that HOT skills are required in solving non routine problem.
3. Anderson and Krathwohl [8] proposed the same definition as in bloom's Taxonomi which are a process that involve analyze, evaluate, and create.

4. Lopez and Wittington [9] believed that HOT skills Appeared when an individual receives new information and the information mixed such that it caused a new arrangement and extent the individual knowledge.
5. Weiss [10] suggested that HOT will appear when an individual faces a Collaborative, authentic, ill-structured, and challenging problems
6. Miri [11] showed that HOT skills are the strategy-where critical, systematic, and creative thinking are activated as a tactics. These activities are needed in order to get the objectives.
7. Rajendran [12] viewed HOT skills as the way to expand the use of mind in facing new challenges
8. Thomas and Thorne [13] defined that HOT skills require to think to higher levels. It requires that individual should deal with the facts, understand them, connect them each other until achieving new or novel knowledge.
9. Kruger [4] believed that HOT skills required the involvement of concept formation, critical thinking, creativity, problem solving, mental representation, rule use, reasoning and logical thinking.

Based on the definition of HOT skills that have been discussed, the further discussion will focus on several properties of HOT skills which are critical, reflective, metacognitive, and creative thinking.

A. Critical Thinking

Wood [15] Defined critical thinking as process of using reasoning in judging the facts and differentiate what is true and what is false. Critical thinking enables individual to assess and calculate situations and create reasonable conclusion. Lipmann [16] viewed critical thinking as skillful, responsible thinking that facilitates good judgment because it relies upon criteria, is self-correcting, and is sensitive to context. It is believed that in order to accomplish a good judgment of situations or facts an individual utilized reasonable thinking and responsible thinking. Another viewed about Critical Thinking Skills are skills that enable one to analyze and synthesize information to solve problems in broad range of areas [17]. It can be concluded that critical thinking is an ability to calculate and assess facts, situations and problems to formulate a good judgment/solution by using reasonable and responsible thinking.

Critical thinking occurs when students construct meaning by interpreting, analyzing, and manipulating information in response to a problem or question that requires more than a direct, one-right-answer application of previously learned knowledge [18]. This can be characterized by specific core thinking skills, which can be developed in the classroom through instruction and guided practice. The list of applicable skills includes, but is not limited to: focusing, information gathering, referencing, organizing, analyzing, integrating, and evaluation. Butterworth and Thaites [19] the core activities of critical thinking are analysis (identifying the key parts of the problem dan reconstructing it in a way that fully and fairly captures its meaning), evaluation (judging how successful a solution is) and further argument (self-explanatory) how the student’s opportunity to give their own response.

B. Reflective thinking

Reflective thinking – as an active, persistent, and careful consideration of any belief or supposed form of knowledge [20]. Taggard and Wilson [21] viewed reflective thinking as process of making informed and logical decisions. Meanwhile, Campbell-Jones & Campbell-Jones [22] recalling one’s own experiences, beliefs, and perceptions. The basic stages of reflective thinking

1. Determination of the problem
2. Reflecting the solution to the problem
3. Design of planning for problem solving process
4. Implementation of the designed plan
5. Performing evaluation by using reflection
6. And continuing by restarting the process in [23]

This give us the big picture that problem solving activity activates students or individuals reflective thinking. In solving a problem, individual is required to understand the problem, planning a way to solve it by utilizing the known and unknown information which is need a reflective thought, implementing the idea, and evaluate the result. In evaluating the result stage, an individual uses reflective thinking to looking back to the information, looking back to blue print of the plan, looking back in implementing the plan and the result. Reflective thinking activity will be well developed when the problem that is used is a complex problems. It will trigger an trial and error activities.

C. Metacognitive thinking

Research in metacognition has been done by many researchers. There are several definitions of Metacognition. Metacognition is the mind's ability to understand, reflect, monitor and control itself or, in other words, metacognition is the ability to know about what we know. [55], defined metacognition as individual's ability to know what he/she knows such as strengths and weaknesses, and using it to next level of knowing. Therefore, metacognitive thinking can be viewed as a person ability to understand their thinking, reflect on the knowledge that they have and using it to develop new knowledge.

D. Creative Thinking

Discussing about creative thinking cannot be separated from creativity. James C Kaufman, Plucker, and Baer [25] provide the definition of creativity as interaction among aptitude, process, and environmental. They believe that an individual or a group is called to be creative if they can produce a perceptible product. The product should be both novel and useful as defined within a social context. Moreover, they categorize the definition of creativity into three categories namely creativity as a person, creativity as a process, and creativity as product. Creativity as person, an individual characteristic is viewed as creator. According to Sternberg [26] , there are three psychological attributes of a person that interrelated with creativity. The attributes are intelligence, cognitive styles, and personality. The intelligence includes verbal knowledge, thinking flow, planning, formulation of the problem, preparation of the strategy, mental representation, decision-making, and globally intellectual integration. The cognitive styles include an individual act in doing things with his/her ways. Finally, the personality is related to personal factors such as flexibility, tolerance for ambiguity, self-discipline, and willingness to take appropriate risks.

Creativity as process is defined as steps in scientific method which are sensing the difficulties or problems, formulating the hypotheses, evaluating and testing the hypotheses, possibly revising and pretesting, and communicating the results [26]. It means that creativity is defined as an actual experience of being creative in encountering reality problems. An optimal experience occurs when an individual is intensely engaged in an activity.

Creativity as product is related to things people make, ideas, and responses. According to Baron (in Munandar [26]), creativity is an individual ability to produce/create new product. The product must be unique and novel to the creator. In this research, the definition of creativity is focused on creativity as product, especially creativity in mathematics problem solving.

In mathematics field, creativity is defined as an ability to combine logical and divergent thinking which is based on intuition but has a conscious aims [27]. The combination of logical and divergent thinking can be varied in different activities. In problem solving, divergent thinking will produce various ideas that might be possible to solve problems and logical thinking will provide considerations in choosing appropriate idea and in making decision. James C Kaufman et al. [25] summarized that there are four aspects of divergent thinking. First, fluency refers to numbers of responses to given stimuli. Second, Originality refers to uniqueness of responses to given stimuli. Third, flexibility refers to number and/or uniqueness of categories of responses to given stimuli. Fourth, elaboration refers to extension of ideas within a specific category of responses to given stimuli.

III. MATHEMATICS PROBLEM SOLVING

Problem solving is a human activity. Individuals encounter problem in their daily life. Therefore, problem solving become common activity by people. The definition of problem solving should be look carefully before the use of problem solving in assessing and developing HOT skills are discussed.

Many scientists have defined problem solving in many perspectives. [28] defined problem solving as a way to find a solution of a problem, so that a clear answer is established. A problem solver is encouraged to find a way or a structure such that the way or the structure can be used to find goals or solutions of the problem. [29] viewed "problem solving as an individual capacity to use cognitive processes to confront and to resolve cross-disciplinary situations where the solution path is not immediately obvious and where the literacy domains or curricular areas that might be applicable are not within a single domain of mathematics, science or reading". Meanwhile [7] considers problem solving as a process of applying previously acquired knowledge to new and unfamiliar (or unforeseen) situations. Despite of the definition that have been proposed, [30] viewed in the way when a problem solving is needed. It is needed when an individual encounter a question or a problem to be solved cannot be done through routine application/procedure of previously acquired knowledge. But it can be solved only when expanded use of mind occurred that a person must interpret, analyze or manipulate information. Based on the definitions, problem solving can be defined as an individual capacity to use cognitive processes to solve question or problem that cannot be solved by routine procedure of previously acquired knowledge.

IV. HIGHER ORDER THINKING SKILLS AND MATHEMATICS PROBLEM SOLVING

Higher order thinking (HOT) skills have strong connection with problem solving activity. It is because HOT Skills are activated when individual encounter unfamiliar problems, uncertainties, questions, or dilemmas [5]. In other words, all of the situations that can develop HOT skills are the characteristics of problem solving activity. Research found that both non-routine and open-ended problems give students more opportunities to demonstrate their problem solving skill. This activity can enhance students' Hot skills. However, if the same types of non-routine problems are given to student repeatedly, the essence to foster HOT skills will be lost (Gerald [31]).

Research that conducting by King, Goodson and Rohani [5] utilized problem solving activities both as a learning strategic to develop HOT skills and as assessment instruments. They believed that questions about dilemma, novel problems, and novel approaches that elicit answers are not learned by the students yet can be effective way to build many skills such as verbal analogies logical thinking, and inductive/deductive reasoning. In assessment of HOT skills, there are three tasks that can be used. The tasks are selection, generation, and explanation. Selection includes multiple-choices, matching, and rank order items. Generations includes short answer, essay, and performance item or tasks. Explanation involves giving reasons for selection or generation purposes.

Moreover, there are many resources (books and journal) discussed about HOT skills with problem solving activities that conducted separately to each skill such as critical thinking ([19], [32], [33]), Reflective thinking ([23], [34]), metacognitive ([35], Mayer [36], [37], [38], [39], [40]) and critical thinking ([41], [42], [43]). The problem that is used in these researches are real life problem, open problem, open-ended problem, non-routine problem, and complex problem. These kinds of problems require problem solvers to think harder in unusual ways since there is no exact formula that can be used directly. Placing problem solvers in a unclear and miserable condition that challenge their way of thinking, various ideas and unknown variable will trigger the activating of HOT skills.

Looking to the opportunity that problem solving activities created to develop students HOT skills, further research in designing problem based instruction in class in developing HOT skills become necessary. This is a vast research area since there only few of researches about that is conducted by utilizing problem solving in developing HOT skills. Moreover, every component of HOT skills also needs a further research.

Abstract**—**Reflective thinking is one of the basic competencies which must be had by students in learning mathematics, especially in solving mathematical problem. The purpose of this study is to describe how reflective thinking is used in solving geometric problem. The subject of this study is a student who has reflective cognitive style enrolled in Mathematics Education, Faculty of Teacher Training and Education (FKIP), Universitas Muhammadiyah Makassar, Indonesia. This study is a descriptive explorative study with data analysis using qualitative approach. Qualitative approach is chosen to describe in depth related to reflective thinking of prospective teacher in solving geometrical problem that can be seen from the subject's behavior in completing a given task and semi-structured interviews are administrated to the subject. During the interview, participant is asked by researcher to describe subject's reflective thinking. There are four main categories to analyze the data related to prospective teacher's reflective thinking in solving geometrical problem: (1) formulation and synthesis synthesis of experience, (2) orderliness of experience, (3) evaluating the experience and (4) testing the selected solution based on the experience

Keywords: *cognitive style, geometrical problem, reflective thinking*

I. INTRODUCTION

Every student must have essential competencies in learning mathematics. One of the essential competencies is students' ability in solving a problem which is suffered or faced. This competence must be recomended to be drilled and appeared since children learn mathematics from elementary school [1], [2]. As a consequence, the handling of mathematical learning process should be done well [3].

In solving a problem, everyone must always involve thinking process, in similiar things that were expressed by Solso [4] that thinking activity is directed to produce problem-solving. Additionally, Siswono [5] stated that thinking is a mental activity which is experienced by someone or a person when they were faced with a problem or situation to be solved or resolved. So it can be concluded that the purpose of thinking is to solve a problem or get answers during students complete math problems, students undertake a process of thinking, so that students can find the answers even if the answer is not necessarily true.

One types of thinking that can be applied in teaching mathematics is reflective thinking [6]. This is due to the learning objectives of mathematics such as comprehension, problem solving, connections of mathematical, mathematical communication and other abilities will be owned by the students well when students are aware of what is right, summed up what it is supposed to do when experiencing failure, and evaluate what has been done.

ISBN 978-602-74529-0-9

.

Some institutions and professional development of teachers have been doing the alternate learning to improve reflective thinking skills that are beneficial to student teachers. Such benefits can be felt during becoming student and after the student completes his education in LPTK (Institutions of Teachers and Education Personnel) [7]. Currently reflective thinking is very interesting to study. This is according to Lim's [8] and Amidu's [9] research which stated that the reflective thinking had become the most prominent issues in the literature, in particular on professional education of teachers.

Reflective thinking done by teacher aims to achieve learning targets and generate new learning approaches that have a direct impact on the learning process. Furthermore, it is explained that the process of reflective thinking can be used by teachers, student teachers and students in the learning process and learning are included in mathematical problem solving [10]. Therefore, it is suggested that teachers need to engage in reflective thinking and not only learn new ideas related to the concept of learning but also involved in the process of solving problems associated with the mastery of concepts or content of the material that is taught so as to improve the quality of professionalism [11].

A teacher who engages in reflective thinking will be critical to the process of resolving the problem which he did. This is in accordance with Kember's opinion [12] which stated that the reflective thinking involves assumptions that are critical to the content or process of solving the problem. In addition, teachers who can reflective thinking can master the concept well. Where the opinion is supported by Barrow stating that reflective thinking in solving problem help someone form concepts and abstractions and develop new concepts that eventually produce a solution of the given problem [13].

Therefore, the professional teacher is a teacher who is able to think reflectively and master the concepts so well that it can explain the material well. A similar sentiment was expressed by Yeo [14] and Thames [15] that a teacher cannot be expected to explain the mathematical concept if it does not have a complete understanding of the mathematical concepts being taught. In other words, teachers' mastery of learning materials (subject matter) becomes very important for success in teaching.

According to Lee [16], there are five phases of reflective thinking, namely:

a) Problem context (identifying the problem)
b) Problem definition (restrict or define the problem)
c) Seeking possible solution (look for possible solutions)
d) Experimentation (using one possible solution of the problem or solution is best done)
e) Evaluation (evaluate / test)
f) Acceptance / rejection (accept or reject)

In addition, Rodgers [11] explained that there are four stages in reflective thinking process, namely:

a) Presence to experience (try to present the experience)
b) Description of experience (describing the experience)
c) Analysis of experience (analyzing the experience)
d) Intelligent action/experimentation (try to practice one of the best solutions in solving problems)

Dewey [17] suggests that there are six phases in reflective thinking:

a) An experience (try to remember things related to the experience before)
b) Spontaneous interpretation of the experience (interpreting spontaneity toward the experience)
c) Naming the problem or question that arise out of the experience (mention any problems or questions that arise from experience)
d) Generating possible explanations for the problem or question posed (building or constructing possible explanations of problems or questions that are given)
e) Ramifying the explanation into full-blown hypotheses (provide explanations in the form of a clear hypothesis)
f) Experimenting or testing the selected hypotheses (practicing or testing the hypothesis chosen)

Based on several previous opinions, the component of reflective thinking process can be illustrated in Table 1 below:

TABLE 1. CONSTRUCTION OF REFLECTIVE THINKING PROCESS

Dewey (1933) (PBRD)	**Lee (2000) (PBRL)**	**Rodgers (2002) (PBRR)**	**Zehavi & Mann (2006) (PBRZM)**	**Reflective Thinking Process**
An experience	*Problem context*	*Presence to experience*	*Selection of techniques*	*Formulation and synthesis of experience*
Spontaneous interpretation of the experience	*Problem definition/ Reframing*	*Description of experience*	*Monitoring of the solution process*	
Naming the problem				
Generating possible explanations for the problem	*Seeking possible solution*	*Analysis of experience*	*Conceptualization*	*Orderliness of experience*
Ramifying the explanations into full-blown Hypotheses			*Insight or ingenuity*	*Evaluating the experience*
Experimenting or testing the selected hypotheses	*Experimentation*	*Intelligent action/ Experimentation*		*Testing selected solution based on the experience*

According to the table, obtained construction reflective thinking process with four stages. These stages are: (1) Formulation and synthesis of the experience; (2) Orderliness of experience; (3) Evaluation of experience; and (4) Testing the selected solution based on the experience. To find out what happens when these stages, the student or the subject will be interviewed in-depth on matters concerning the four stages and linkages that may affect it.

By reflective thinking, students can solve more complex problems because the tought of students will be directed and students think reflectively toward solution or settlement of the problem being solved tend to be true and correct. This is according to research King and Kitchener [18] which states that the reflective thinking help somebody in solving complex problems, due to reflective thinking helps a person identify concepts, facts, formulas, and theories that are relevant to the solution of problems identified. In addition, reflective thinking also involves the process of analyzing, comparing, synthesize, clarifying, and choosing what someone is doing that shows the reflection itself [19], [20].

When someone does the activity of analyzing, comparing, synthesize, clarifying, and choosing, then he or she will do it in different ways based on their character. Everyone has a character different or unique [21], so as to learn, master, process information, solve problems, and to teach the material well, in this case the mathematics, someone will do it in a way that is different also [22].

Every students has a cognitive style. Differences in cognitive styles have affected the ability of students in reflective thinking and solving problems. This is in accordance with the opinion of Coop and Sigel that the cognitive styles correlate with intellectual and perceptual behavior. Intellectual associated with a person's ability to think, while perceptually associated with a person's ability to view or interpret anything.

A number of cognitive styles have been identified in the literature, for example, Abdurrahman [23] states that one of the dimensions of cognitive style that is enough to attract attention in assessing children who have difficulty in learning is a cognitive style impulsive-reflective (to answer the problem quickly, but a lot of mistakes and addressing slow but less error prone).

Jerome Kagan introduced impulsive and reflective cognitive styles in 1965. Kagan classified the cognitive styles based on the amount of time which is used by a person in responding to a situation and the accuracy of the answers of the response given. People who have the characteristic uses short time in addressing the problem, but no/less careful so that the answers tend to be wrong, called the person who had an impulsive cognitive style. Meanwhile, people who have the characteristic uses long time in answering the question, but carefully/meticulously so that the answers given tends to be true, called people who have cognitive style reflective.

With the cognitive styles are different, there is the possibility of students solve problems in different ways, according to the reflective thinking skills and his perceptions of a given problem. To find out if it really happens, it needs to be explored further.

.

II. METHOD

This type of research is a descriptive study with qualitative approach which aims to describe in depth about the student's reflective thinking process in solving geometrical problem based on cognitive style. To get description of student's reflective thinking process who has reflective cognitive style in solving geometrical problem, subject was given a task of solving geometrical problems which are presented. Furthermore, subject was interviewed to dig deeper into how students think and acquire new information that may be obtained from the task which is performed by subjects. Data from duties and the interviews were analyzed and further described in the form of written words or a description of the subjects.

The research was conducted in Department of Mathematics Education, Faculty of Teacher Training and Education (FKIP), Makassar Muhammadiyah University. Subjects in this study were student teachers in academic year 2013/2014 (fifth semester). Determination of research class is based on the consideration that students in semester VI have enough time, so that making it easier to do the interview.

The purpose of this study was to analyze the ability of preservice teachers' reflective thinking process in solving geometrical problem who has reflective cognitive styles. To achieve this goal, several stages will be carried out as follows: (a) the first stage, the determination of research subject who has cognitive style of reflective by using specific criteria ; (b) the second phase, preparing problem solving tasks which can describe or appeare reflective thinking process of subject that has been validated by several experts; (c) The third stage, interview which is not structured, informal to verify the data from tasks of problem solving; (d) The fourth stage, recording with the recorder and use the records. This meant that no information is missed or lost during the interview; (e) the fifth stage, analyzing of research data related to the process reflective thinking in solving geometrical problems by subjects (preservice teachers).

This research is exploratory descriptive study with data analysis by qualitative approach which main data in the form of words that are linked into sentences. Qualitative method is chosen for profile students' understanding of the natural background and the main instrument is the researcher's own research. It means that the data which is analyzed in form descriptive and not in the form of figures as well as in quantitative research.

To obtain valid data in this study, then do the validation data. One of the qualitative research validation procedures that can be performed is by means of triangulation. Validation of the data in this way is done by repeatedly checking with different time. Sugiyono [24] called the data validation process by triangulation of time.

III. RESULT

Based on the result of construction reflective thinking process which is divided into four stages. These stages are: (1) Formulation and synthesis of the experience; (2) Orderliness of experience; (3) Evaluation of experience; and (4) Testing the selected solution based on the experience. To find out what happens on every stage related to reflective thinking in solving geometrical problem, the participant or the research subject will be interviewed in-depth on matters concerning the four stages and linkages that may affect it.

The results of task-based interview of the subject on data collection that illustrates the process of reflective thinking in solving geometrical problems by preservice teacher who has reflective cognitive style as follow.

The first stage, **formulation and synthesis of the experience**, the participant described problem by using his own word, the participant explained problem clearly related to the main point from the problem. The participant also can find the concepts which are related to the problem given. For more clearly, the following is a transcript of the interview excerpt based on this stage.

P Baik. Kira-kira, jika dengan menggunakan bahasa ade sendiri, apa yang adik pahami tentang soal ini secara keseluruhan?

S Terkait pemahaman saya terhadap soal ini yang saya pahami adalah, yaitu soal ini menuntut kita untuk mencari sebuah luas.

P Luas apa?

S Luas dari taman bunga, yang berbetuk persegi atau persegipanjang tapi belum diketahui panjang sisi-sisinya, entah itu apakah panjangnya atau lebarnya, tergantung nanti proses penyelesaian soal saya seperti apa.

P Terus?

S Pada soal ini juga, memuat beberapa konsep persegi atau persegipanjang, konsep luas, perkalian, konsep perbandingan, kensep sudut, dan konsep kesejajaran.

From the transcript above, it can be explained that the participant described the problem by using another word however participant's explanation still has the same idea from the problem. Furthermore, when the subject identified concept or subject matter which is related to the problem, the participant mentioned not only the concept that ever the participant used in solving a problem before, but also the participant explained that the concept which will be used in solving the geometrical problem. For more clearly, the following is a transcript of the interview excerpt based on this stage.

P Sebelumnya, apakah adik pernah melihat soal seperti ini?
S Nda persis sih soalnya seperti ini, tapi dalam kehidupan sehari-hari atau di sekolah, biasanya, inikan berbentuk soal cerita. Kalau soal cerita seperti ini, biasanya itu, memuat konsep aljabar.
P Memuat konsep aljabar, maksudnya?
S Dalam kehidupan sehari-hari, biasanya kalau soal cerita pada kehidupan sehari-hari itu, bisanya memuat pemisalan seperti seseorang membeli buku, bukunya itu diganti dengan x berapa buah. Kalau misalnya kita membeli 3 buku, kita bisa menuliskan 3x.
P Ok kalo begitu, dulu ketika menghadapi soal yang seperti ini konsepnya terkait apa saja?
S Kalau soal yang dulu, biasanya langsung terkait konsep aljabar,konsep sudut, konsep segitiga, persegi, persegipanjang.
P Masih ada lagi konsep yang lain terkait soal yang pernah ade hadapi?
S Hmm, oh konsep lingkaran pak. Yah mencari luas lingkaran, keliling lingkaran. Ya itu pak.
P Coba, perhatikan soal tersebut dengan seksama yang ada dihadapan ade itu. Soal tersebut terkait dengan konsep apa saja?
S Hmm, pertama pasti terkait dengan konsep persegipanjang. Karena dalam soal sudah disebutkan bahwa taman bermainnya berbentuk persegipanjang. Yang kedua, juga ada konsep sudut. Ketiga konsep perbandingan, ke empat konsep kesejajaran, konsep luas, juga konsep perkalian.
P Kok konsep perkalian?
S Kalau konsep perkalian kan akan dibutuhkan pada saat menghitung luas dari taman bunga.

The second stage, **orderliness of experience**, the participant described strategy in solving the geometrical problem given. The participant explained the steps in choosing operation well related to the problem. For more clearly, the following is a transcript of the interview excerpt based on this stage.

P Baik, dengan informasi yang anda peroleh kira-kira strategi apa yang anda gunakan untuk meyelesaikan soal ini?
S Dari informasi yang diperoleh atau yang diberikan dari soal ini, pertama-tama yang saya kerjakan terlebih dahulu adalah menggambar pak.
P Apa yang kamu mau gambar?
S Ehhh, taman bunganya pak. Ehh taman bermainnya pak. Saya menggambar bentuk taman bermainnya serta menggambar taman bunga yang ingin dicari luasnya pak.
P Ok. Sekarang, saya tanya lagi. Kamu kok menggambar? Padahal kan soalnya tidak menuntut kamu menggambar?
S Ehh, bagi saya pada soal ini, memang tidak meminta saya menggambar. Tetapi, untuk memperoleh informasi yang lebih jelas, dan akurat. Saya kira kita harus menggambar terlebih dahulu, supaya kita bisa memahami dengan jelas, maksud dan tujuan dari soal ini.
P Ok. Terus setelah menggambar apalagi?
S Setelah menggambar saya, mencatat apa-apa yang diketahui dari soal pak. Contohnya, sudut yang diketahui dari soal yaitu sudut 45 derajat dan gambaran saya itu, saya mengumpakan bahwa sudut SPD itu 45 derajat.
P Sudut SPD?
S Iya Pak, sudut SPD seperti pada gambar ini pak (sambil menunjukkan hasil dari gambar subjek berdasarkan hasil gambaran yang diperoleh dari soal). Ini sudut A, sudut B, C dan D yang diberikan dari masing-masing dari sudut taman bermain itu adalah 90 derajat. Sudut SPQ itu juga 90 derajat dari sudut masing-masing taman bunga.
P Ok. Terus apalagi?
S Saya, menuliskan juga apa yang ditanyakan. Pada soal ini kan yang ditanya itu luas taman bunga. Pada penyelesaian ini, saya umpakan taman bunga sebagai persegipanjang PQRS.

The participant also can explain the difficulties when the participant tried to apply the strategy to solve the problem given. The following is a transcript of the interview excerpt based on this stage.

P Ok, sekarang, jadi kesulitan yang anda hadapi untuk menerapkan strategi ketika menyelesaikan soal ini adalah?
S Itu tadi pak, eehh, yaitu mengaitkan antara konsep satu dengan konsep lainnya, agar tidak terjadi kesalahan dalam pengerjaan. Misalnya yang tadi ini, konsep sudut dengan konsep segitiga. Konsep perbandingan pada ruas garis, kemudian mengaitkan konsep sudut
P Maksudnya?
S Inikan nantinya, maksudnya prinsip-prinsip sudut, contohnya sudut berpelurus. Jumlah sudut berpelurus itukan sama dengan 180 derajat, maka dengan jumlah keseluruhan sudut yang terdapat pada pada garis lurus itu 180 derajat pak.

From the explanation above, it can be concluded that at this stage, the participant gave an explanation how choose a operation or strategy accurately and the participant can find difficulties and explain it related to the strategy chosen.

The third stage, **evaluation of experience**, the participant can find also strengths and weaknesses of solutions that had been done and explain how the effort to improve the weaknesses that are owned or carried when solving problems. For more clearly, the following is a transcript of the interview excerpt based on this stage.

.

P Coba kamu sebutkan kelebihan dan kekurangan terkait penyelesaian yang kamu lakukan
S Kelebihannya itu pak, bisa memindahkan informasi dari bentuk soal ke dalam bentuk gambar, bisa memberikan informasi yang lebih jelas lagi. Saya mudah mengeceknya kembali apabila mau dikroscek kembali dari awal karena penyelesaiannya saya itu secara runtut. Kekurangannya mungkin butuh waktu yang agak lama karena harus lebih teliti. Contohnya saja tadi, karena saya kurang teliti terdapat sebuah kesalahn dalam penulisan operasi, contohnya tadi itu, tadi saya tulis tambah, tapi setelah saya cek kembali, saya tahu kesalahan saya berada saya di situ.
P Tadi itu kan kamu menyebutkan kelebihan dan kekurangan terkait penyelesaian yang kamu lakukan. Sekarang, kira-kira, upaya apa yang anda lakukan untuk mengurangi kelemahan ketika menyelesaiakan soal?
S Ehh, mungkin upaya yang saya lakukan yaitu, contohnya lebih konsentrasi dalam menyelesaian soal
P Kenapa?
S Saya sadar betul, bahwa dalam menyelesaikan soal apapun itu bentuknya, seseorang harus lebih tenang, konsentrasi, dan rileks. Kemudian kita bisa berpikir lebih jernih dalam menyelesaikan soal.

From the transcript of interview above, it can be concluded that the participant can give the explanation about strengths and weaknesses from the solutions which had been done, namely the participant can formulate or transform from verbal to picture or other forms. On the other hand, the participant can explain the effort to revise and improve the weakness that are owned or carried when solving geometrical problems, for example; when the participant resolve any matter that are in any forms, the subject of research must be calm, concentration, and relax. Then we can think more clearly in solving gemetrical problems.

The fourth stage, **testing the selected solution based on the experience**, the participant explained whether the answers or solutions which are obtained can answer the issues presented and explained how to test the internal consistency or error in operation or in the solution from the problem solving which had been done. For more clearly, the following is a transcript of the interview excerpt based on this stage.

P Menurut Anda, penyelesaian yang anda lakukan ini telah menjawab permasalahan dari soal ini
S Sudah pak
P Apa permasalahan dari masalah atau soal ini?
S Permasalahna dalam soal inikan menentukan luas taman bunga
P Apakah kira-kira sudah menjawab permasalahan ini?
S Sudah pak, kan permasalahan dalam soal ini adalah mencari luas taman bunga yang berbentuk persegipanjang jadi saya mencari panjang dan lebar dari taman bunga dan saya sudah menemukan panjang dan lebar dari taman bunga, kemudian saya operasikan lalu akhirnya saya mendapatkan luas dari taman bunga ini.
P Jadi yang anda lakukan untuk meyakinkan bahwa penyelesaian yang anda lakukan ini sudah menjawab pertanyaan dari permasalah soal ini adalah?
S Karena, untuk menentukan luas dari taman bunga ini, yang saya butuhkan adalah panjang dan lebar dari taman bunga ini kemudian panjang dan lebar dari taman bunga saya sudah temukan
P Tapi kamu yakin dengan panjang dan lebar yang kamu temukan itu?
S Yakin pak
P Mengapa anda yakin dengan ukuran panjang dan lebar yang anda temukan itu?
S Ehhh, karena dari proses penyelesaian ini, setelah melihat kembali, dan mengecek kembali ini sudah, semuanya sudah memenuhi prosedur tetapi jika perlu saya akan menyelesaikan soal ini dengan cara yang berbeda.
P Maksudnya dengan cara yang berbeda?
S Ahhh, kan bisa saja ini soal bisa diselesaikan dengan beberapa cara, untuk meyakinkan jawaban saya kembali. Saya bisa menggunakan cara yang lain untuk menyelsaikan soal ini dan apabila jawabannya sama, maka jawaban saya ini saya sangat yakin sudah benar
P Apanya yang anda bandingkan? Ketika anda menyelesaikan soal ini.
S Ehhh, jawaban terakhirnya pak. Luas taman bunga, apabila luas taman bunga yang saya peroleh sama dengan cara berbeda maka saya yakin ini sudah benar

From the transcript of interview above, it can be concluded that the participant can give the explanation about the answers or solutions which are obtained from the solutions which had been done had answered the geometrical problem given, namely the participant can find the point from the problems (length and width of flower garden) which can help in finding the area of flower garden. Although, in the problem, the length and width are not mentioned specifically, the participant can find them and they help the participant in solving geomterical problem or finding the solutions. Furthermore, to test the internal consistency or error in operation or in the solution, the participant checked and looked back related procedures and operations which is used. Moreover, the participant tried to resolve the problem in a different way to compare the answers which had been obtained before.

IV. CONCLUSION

From the results of this study, it can be concluded that the participant can solve the geomterical problem by using his reflective thinking in four stages. The four stages are:

1. The first stage, **formulation and synthesis of the experience**, the participant described problem by using his own word, the participant explained problem clearly related to the main point from the

problem. The participant also can find the concepts which are related to the problem given. Furthemore, the participant described the problem by using another word however participant's explanation still has the same idea from the problem. Moreover, when the subject identified concept or subject matter which is related to the problem, the participant mentioned not only the concept that ever the participant used in solving a problem before, but also the participant explained that the concept which will be used in solving the geometrical problem.

2. The second stage, **orderliness of experience**, the participant described strategy in solving the geometrical problem given. The participant explained the steps in choosing operation well related to the problem. Further, the participant gave an explanation how choose a operation or strategy accurately and the participant can find difficulties and explain it related to the strategy chosen.
3. The third stage, **evaluation of experience**, the participant can find also strengths and weaknesses of solutions that had been done and explain how the effort to improve the weaknesses that are owned or carried when solving problems. It means that the participant can give the explanation about strengths and weaknesses from the solutions which had been done, namely the participant can formulate or transform from verbal to picture or other forms. On the other hand, the participant can explain the effort to revise and improve the weakness that are owned or carried when solving geometrical problems, for example; when the participant resolve any matter that are in any forms, the subject of research must be calm, concentration, and relax. Then someone can think more clearly in solving gemetrical problems.
4. The fourth stage, **testing the selected solution based on the experience**, the participant can give the explanation whether the answers or solutions which are obtained can answer the issues presented. In addition, the participant can explain how to test the internal consistency or error in operation or in the solution from the problem solving which had been done. For example, the participant checked and looked back related procedures and operations which is used. Moreover, the participant tried to resolve the problem in a different way to compare the answers which had been obtained before.

A Study of Late Formal-Junior School Student's Geometric Thought in Understanding the Relationship Between Quadrilateral

Agustan S.
Fakultas Keguruan dan Ilmu Pendidikan (FKIP)
Universitas Muhammadiyah Makassar
Indonesia
agus.sahabat@gmail.com

***Abstract*—**Currently, geometric thought is one of the important things which become a concern in learning mathematics, especially in learning of geometry. Learning of geometry must be allowed to the students' geometric thought will enhance the intellectual engagement of students, because it can help the student in directing his thoughts so that the solution of the problem being solved tends to be true and correct. The purpose of this research paper is to describe how geometric thought is used in understanding the relationship between quadrilaterals. The participant of this research is a student who is at the early formal operational stage based on Piaget's development of cognitive enrolled in class VIII SMP, Kabupaten Bone, South Sulawesi, Indonesia. This research is a descriptive explorative study with data analysis using qualitative approach. Qualitative approach is chosen to describe in depth related to student's geometric thought in understanding the relationship between quadrilateral that can be seen from the subject's behavior in completing a given task and semi-structured interviews are administrated to the subject. During the interview, participant is questioned by researcher to investigate subject's geometric thought. To test the credibility of the data, the researcher used triangulation time. The results of this research showed that the student who is at the late formal operational stage based on Piaget's stages of cognitive development stringing up or composing 7 relationships from 15 relationships between quadrilaterals and the student or subject drew various kinds quadrilateral by using 4 attributes i.e. position, the size, shape of quadrilateral and rotational symmetry.

Keywords: *Geometric Thought, Late Formal Stage, Quadrilateral*

I. INTRODUCTION

Geometry is one subject that addresses school math objects associated with spaces of varying dimensions. The concept of geometry itself occupies a special position in the secondary mathematics curriculum because it is closely related to other forms of objects that are often encountered by students in everyday life. Various opinions appeared that discusses geometry both definitions and chances to be taught in SMP [1]. One of the shapes is taught in junior class VIII is a quadrilateral. Topics include the quadrilateral parallelogram, rhombus, rectangle, square, trapezoid, and kite. Muser [2] defines that the types of quadrilateral as follows: A square is a quadrilateral with four sides the same length and four right angles. A rectangle is a quadrilateral with four right angles. A parallelogram is a quadrilateral with two pairs of parallel sides. A kite is quadrilateral with two no overlapping pairs of adjacent sides that are the same length. A rhombus is a quadrilateral with four sides the same length. A trapezoid is a quadrilateral with exactly one pair of parallel sides.

One of the relationships between the various types of quadrilateral described by Soedjadi [3] based on the intention can be seen in Figure 1. below:

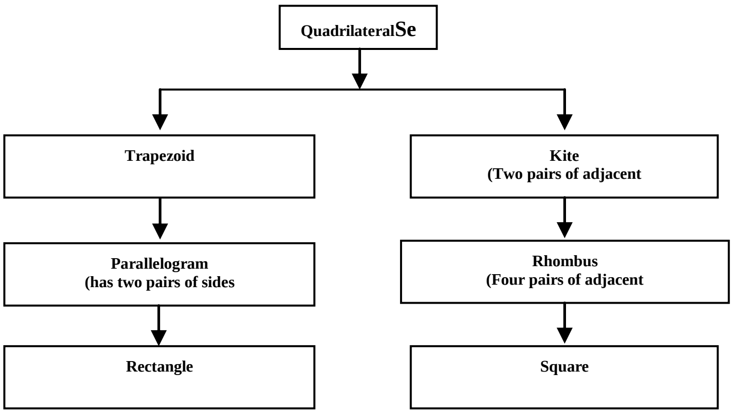

FIGURE 1. THE RELATIONSHIP BETWEEN VARIOUS TYPES OF QUADRILATERALS

Based on the picture above, trapezoid is is defined using the genus proksimum (closest family) "quadrilateral" by adding the terms "has a pair of parallel sides". Thus the trapezoid is is a quadrilateral which has a pair of parallel sides. In a similar manner, a trapezoid is parallelogram which has two pairs of parallel sides and a rectangle is a parallelogram that has a right-angle. Likewise for kite defined as a quadrilateral having two pairs of adjacent sides equal in length. Rhombus is a kite that four adjacent sides of equal length. Square is a rhombus is has a right-angle.

Related to the topic of the quadrilateral as one of the subjects in the field of geometry taught in junior high, Sunardi [4] found many students were wrong in solving the problem of parallel lines. Based on this, the geometry is looked as part of math given to students classified as difficult. Students' s learning difficulties can not be separated from the practice of learning that has been in progress [5]. Idris [6] suggested that learning of geometry is not easy and some students fail to develop an understanding of the concept of geometry, geometric reasoning and skill to solve the problems of geometry. Furthermore, Idris stated that a number of factors that lead learning of geometry is difficult which they are language of geometry, visualization and learning abilities are less effective for the low mastery of facts, concepts and principles of geometry.

According Soerjono [7] one of among the causative factor is the intellectual ability of students. The results of Burger and Shaughnessy's research [8] demonstrated that the intellectual ability of students plays an important role in the mastery of facts and concepts of geometry. Intellectual abilities are spatial ability and auditory ability which are very close relationship with the cognitive aspects of students in general. Research shows that the understanding of spatial knowledge can affect the performance related to academic tasks especially math, reading and science [9]. According to Piaget and Inhelder [9] states that spatial ability which is an aspect of cognition that develops in line with the cognitive development.

Piaget [10] describes the sequence into four stages of cognitive development which is qualitatively different, namely: (1) the stage of sensory motor (2) pre-operational stage, (3) the concrete operational stage, and (4) the formal operational stage. He claimed that all children pass through four stages with different speeds, but none of the children who passed through one of the four stages [10, 11]. Piaget suggested that students should use logical operations to get structure of knowledge and their changes [12]. The more often children move and find new things, the children will increasingly have new schemes that are used to develop their logical operation [11].

Formal operational by Sawyer et al, Dickinson and Lee in Philip Adey split into 2 of the formal operation of early formal operations and late formal operations [12]. Students at the early formal have a good effort to solve the problems by using all its logical operations. The resulting solution is correct but there are little mistakes in using a type of logical operation. They can predict the final answers so that any data and information geared towards achieving that goal. Students at the late formal is able to answer correctly. They show the use of logical operations well. They relate the data and information to resolve pemasalahan. If there is an impasse in resolving a problem they can find another alternative. Children demonstrate a broad understanding of the problem, using a cognitive schema to build understanding of the structure of the problem, as well as choosing the right strategy. By using the scores as a basis and pay attention to the level of understanding of the students showed in solving problems, level of cognitive development of students based on tests of logical operations Piaget classified as shown in Table 1 below.

TABLE 1. LEVEL OF STUDENTS'S COGNITIVE DEVELOPMENT BASED ON TEST OF LOGICAL OPERATION PIAGET

Interval Score	Level Of Students's Cognitive Development
0-35	Early Concret
36-70	Late Concret
71-105	Early Formal
106-140	Late Formal

(Adopt from Loengson dan Limjap, 2003: 13-14)

II. METHOD

This research is exploratory descriptive study with data analysis by qualitative approach which main data in the form of words that are linked into sentences. Qualitative methods is chosen for profile students' understanding of the natural background and the main instrument is the researcher's own research. It means that the data which is analyzed in form descriptive and not in the form of figures as well as in quantitative research.

This research was conducted in Watampone, Bone district, Makassar, South Sulawesi. The participant in this study is student of class VIII SMP. The reason for choosing a class VIII student junior high school student is at the stage of formal operations, so that students are able to think more abstractly, capable of inductive and deductive thinking and be able to think logically.

To determine the stage of cognitive development of students who are at the late formal stage, then used the test instrument Logical Operations Piaget (Piaget TOL) developed by Leongson, JA & Limjap, AA (2003). The instrument is a matter of form description which consists of 35 questions. With reference to the opinion of Schoenfeld and Avalanche & Limjap, researchers determined the students' level of cognitive development by Piaget logical operation test. If the scores obtained by students 106-140, the level of cognitive development of students at the level of late formal.

To obtain valid data in this study, then do the validation data. One of the qualitative research validation procedures that can be performed is by means of triangulation. Validation of the data in this way is done by repeatedly checking with different time. Sugiyono (2005) called the data validation process by triangulation of time.

III. RESULT

The results of task-based interview of the subject on data collection that illustrate understanding of the concept of quadrilateral of student through drawing, identifying and making diagram of relationships between quadrilaterals as follows.

Junior high school students with stage of cognitive development at the stage of **late formal operations** when drawing rectangles, students can draw variety of different rectangular shapes are infinite by paying attention to the attributes of the shape, the size and position of quadrilateral

More clearly on task-based interviews, **the activities of subject when drawing a quadrilateral**, the subject drew quadrilateral by paying attention to characteristics or attributes of quadrilateral drawn as in the following figure 2.

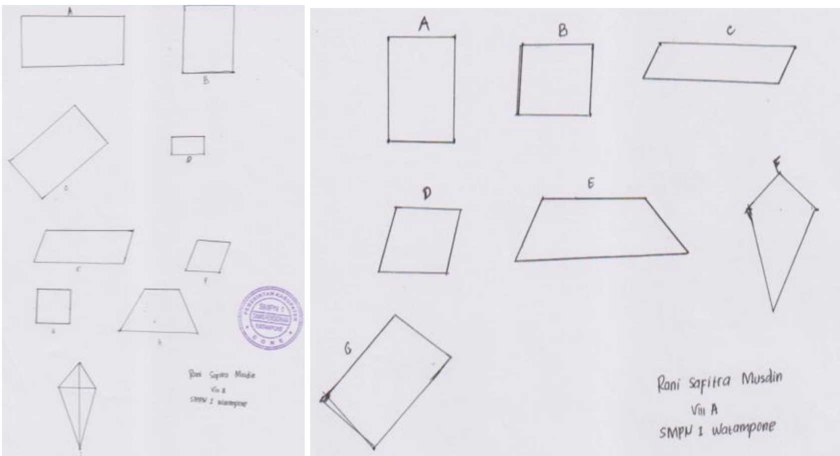

FIGURE 2. VARIOUS QUADRILATERAL DRAWN SUBJECT AT THE INTERVIEW

The following is a transcript of the interview excerpt based on the task of drawing quadrilateral

AG085	P	"Dari gambar bangun segiempat yang berbeda-beda itu, sekarang saya mau tanya. Berapa banyak bangun segiempat berbeda yang dapat kamu gambar?
RS086	R	"Enam"
AG089	P	"Ada enam? Yakin?"
RS090	R	"Yakin"
AG091	P	"Tapi tadi kamu menggambar segiempat lebih dari enam"
RS092	R	"Iya, tapi A,B,C dan D itu sama-sama persegi panjang cuma yang membedakan hadapannya, posisinya dan ukurannya"
AG093	P	Jadi dengan memperhatikan perbedaan tersebut, kembali saya mau tanya Rani, kira-kira Rani bisa menggambar bangun segiempat berapa banyak yang berbeda?"
RS094	R	"Enam"
AG095	P	"Enam, mengapa mereka berbeda satu sama lain?
RS096	R	"Ada yang berbeda posisinya, ada yang berbeda bentuknya, hadapannya dan ukurannya.
AG097	P	"Jadi Rani bisa menyimpulkan dapat menggambar bangun segiempat berapa banyak?"
RS098	R	"Banyak"
AG099	P	"Banyak, maksudnya?"
RS100	R	"Tak terhingga"
AG101	P	"Kok bisa?"
RS102	R	"Karena kita bisa menggambar segiempat beda posisi, beda ukuran, dan beda bentuk dan putaran"

From the transcript of interviews and the results of drawing quadrilateral above, data showed that the subject can draw various kinds quadrilateral by taking into differences in the difference of position, size, shape and rotational symmetry.

The activities of subject when identifying the differential quadrilateral, subjects pays attention three attributes of quadrilateral based on size of the side, kind of quadrilateral (trapezoid) and position While at identifying the same quadrilateral, subject attentioned attribute number of pairs of opposite sides and parallel, the angle of sight, the existence of a right angle which is owned by the rectangle and the size of both the adjacent sides or opposite sides and parallel. Definition of quadrilateral which is made by the subject accurate and inaccurate depending on the definition of quadrilateral used as a reference in defining a quadrilateral.

Clearly explained that the subjects make inferences when:

a. Identifying Parallelogram

1. Student identifies several different models by taking into the attributes of size of parallelogram and the position of parallelogram.
2. Student identifies some of the same characteristics of parallelogram by regarding the attribute size of side and having two pairs of opposite sides parallel and opposite sides of the same length.
3. Referring to the definition of parallelogram is a quadrilateral of which two pairs of parallel opposite sides, or two pairs of opposite sides of equal length, or a pair of parallel opposite sides of the same length, then the attributes given by subject to construct a definition parallelogram is accurate.

b. Identifying Rectangle

1. Student identifies several different rectangular models by taking the atribute of size and the position of rectangle.
2. Student identifies a common characteristic of some rectangles that four corners is right angle, opposite and parallel sides equal in length.
3. Referring to the definition of a rectangle is a parallelogram whose one of the corners is right-angled, the attributes given by subject to construct a definition of the rectangle is inaccurate.

c. Identifying rhombus

1. Student identifies several rhombus in different models with regard to the attributes of size and position of the shape.
2. Student identifies a common characteristic of some rhombus that all sides of rhombus has the same length, opposite angle is equal.
3. If the definition refers to a rhombus is a quadrilateral whose four sides the same length as the attributes of a given by subject to build rhombus definition is accurate.

d. Identifying square

1. Student identifies some square in different models with regard the zise and position of the shape.

2. Student identifies the characteristics of some models of the same square i.e., all sides is equal in length and becomes right angel, opposite sides are parallel and equal in length.
3. If the definition refers to the square is rhombus which one of its angles is right angel or quadrilateral whose four sides the same length and the angle is right angel, then the definition given subject is inaccurate.

e. Identifying Trapezoid

1. Student identifies several trapezoids in different models with regard to side length and size attributes, position and the kinds of trapezoid.
2. Student identifies the characteristics of some models of trapezoids which have one pair of parallel opposite sides and the parallel sides of unequal length.
3. If the definition refers to the trapezoid is a quadrilateral having parallel opposite sides or rhombus which has only a pair of parallel opposite side, then the definition given subject is accurate.

f. Identifying Kites

1. Student identifies several kites in different models with regard to size of the kites and position of kites
2. Student identifies the characteristics of some models of kite is adjacent sides of the same length and opposite sides of unequal length, opposite angle is equal.
3. If the definition refers to a kite is quadrilateral that has two pairs of adjacent sides of the same length and the sides do not overlap, then the definition given by subject is accurate.

In the activities of making diagram of relationship between quadrilateral, subject made diagram relationships between quadrilateral as in Figure 3. The following

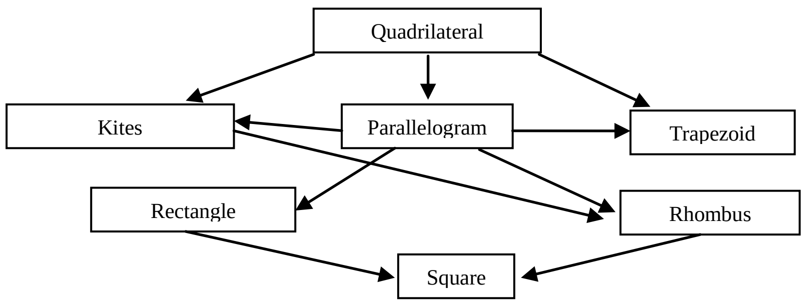

FIGURE 3. RELATIONSHIP OF VARIOUS TYPES OF QUADRILATERAL MADE BY SUBJECT

IV. CONCLUSION

From the results of this study concluded that:

1. If it is viewed from the standpoint of analytical, the definition made by subjects who is at the late formal operation presents relationship 7 relationships between quadrilateral possible. Shrinkage occurs relationship of 7 who may be 15 possible relationship. This shrinkage occurs because there is a genus that are used but not genus proksimum
2. Based on the understanding which is recognized by the subject who is at the stage of late formal operation, trapezoid is a quadrilateral which has a pair of parallel sides and a kite is a quadrilateral which is two pairs adjacent sides has the same length, then these results can be interpreted that the subject makes sense analytically.
3. There are 21 possible relationships between quadrilateral parallelogram, rectangle, rhombus, square, kite, and trapezoid. From 21 of this relationship, there are only 12 probably connections which is made by the subject, it is caused by definition trapezoid is a quadrilateral which h as opposite sides parallel and equal in length.
4. Subject recognized two accurate definition of 6 accurate definition which might and subject made 8 analytical definitions of 8 analytical definitions probably and 6 of them are accurate.

V. SUGGESTIONS

Based on these results, some suggestions have to be submitted as follows:

1. From the results of this research, in general student's understanding who is at the stage of late formal operations can understand the relationship between quadrilateral well but is less able to pay attention to or identify the relationship both similarities and differences of quadrilateral. Therefore, the researchers suggested that the educators must pay attention the stage of cognitive development of students in learning, particularly in understanding the relationship between quadrilaterals.
2. In the activities drawing quadrilateral. There is student's tendency, in this study, to draw a quadrilateral by starting from images that is very familiar for subject or often encountered and recognized by subject as a rectangle and a square. Likewise, when subject made diagram relationship between quadrilaterals, the tendency was happening again. Subjects tended to start from rectangle and connect it to the square. This indicates that the learning process in schools especially for quadrilateral, teachers often taught students ranging from rectangle or square so that students are only very familiar with both of them. Therefore, researchers also suggest to educators to teach not only the quadrilateral from a square or rectangle but start another quadrilateral such as parallelogram, rhombus, kite and trapezoid.

ACKNOWLEDGMENT

I would like to express my deepest appreciation to all those who provided me the possibility to complete this report. A special gratitude I give to Lecturer, Prof. Dr. Mega Teguh Budiarto, M.Pd., whose contribution in stimulating suggestions and encouragement, helped me to coordinate my resesearch especially in writing this report.

asyukriani@yahoo.co.id

Abstract-Adaptive reasoning and strategic competence are two important components that can be assembled into a logical steps in solving mathematical problem so that they reflect a math proficiency. This paper describes the adaptive reasoning and strategic competence of student in solving contextual mathematical problem designed to involve settlement through some mathematical concepts and efficient strategies to formulate, represent, and solve problem situation. Cognitive styles and gender of students are assumed to make an impact on mental activity student in solving mathematical problems involve adaptive reasoning and strategic competence. Thus, in depth interviews carried out to a eleventh-grade male senior high school student and has cognitive style Field Independent (FI). Male-field independent (FI) student related the concept of mathematical to situation mathematical problem encountered clearly and completely that appropriate with the rules of the concept. In addition, male-field independent (FI) student used reading and imagining strategies in understanding the problem situation, used verbalizing strategy in formulating the problem situation, used imagining, symbolizing and verbalizing strategies in representing the problem situation and then solved the problem analytically.

Keywords: a*daptive reasoning, field Independent, gender, mathematical problem solving, strategic competence*

I. INTRODUCTION

This paper presents the investigation of adaptive reasoning and strategic competence in solving mathematical problem. Kilpatrick [1] revealed five strands that are entwined shaped mathematical proficiency. The five components are conceptual understanding, procedural fluency, strategic competence, adaptive reasoning, and productive disposition. Five strands are not independent, but rather entwined form a bond with each other and influence each others to establish mathematical proficiency. This suggests that the two strands of the adaptive reasoning and competence strategies also influence each other. Adaptive reasoning and strategic competence are two key component that reflect understanding of mathematics [2]. Both adaptive reasoning and strategic competence respective have many aspects that are assembled into a logical sequence in solving mathematical problem.

Adaptive reasoning refers to mental activities adapt mathematical concepts, facts, procedures, and methods into mathematics problem situation and than provide explaination, justifying and reflection regarding relationship between concepts and situation. Strategic competence refer to mental activities apply strategy to formulate, representate, and solve the problem situation [1]. Having an excellant adaptive reasoning and strategic competence, means that the students have been successful in learning and has established a mathematical proficiency. The realization of success in learning is not only seen on the ability of students to arrived to solution of the mathematical problem, but is also capable of logical thinking to provide an explanation and justification of the results of their thinking and strategy of solutions used in the process of mathematical problem solving. As the opinion of Kilpatrick[1] and Herbert [3] that every experience in solving problems, students should also be able to think logically to explain and justify each of solution and results of their thinking to others. According Skemp [4] that knowing something is done without a coherent reason is a form of instrumental understanding. Then

Skemp [4] identified the primacy in mathematics learning is to build understanding of "relational" than understanding "instrumental".

The tendency of students through the process of mental processing information to produce a solution of the problem situation is called cognitive style. According to Kuo [5] that cognitive style refers to how the tendency of individuals to organize and represent information. According to Leng [6] that describes how the cognitive styles of students to recognize and represent a problem, plan, produce and execute a plan, determine and evaluate the solution when students think about how to solve the problem-solving task. Cognitive styles directly related to the thought processes which form the results of his thinking in accordance with the characteristics of the student. Field-dependent (FD) and field-independent (FI) cognitive style is one dimension of cognitive style that most attention in the educational implications [7]. According to Kuo [5], FI student is internally directed and process information with their own structure, analyze problems that require all elements in the context, as well as accept the idea reinforced through prior analysis. Holmes [8] concluded FI Students set their own standards for thinking and behaving. FI students active and goal oriented. FI students have excellent logical reasoning and analytical reasoning skills. According to Johnstone and Al-Naeem, FI students can capture the essence of the problem and ignore unimportant information that is not excessive in processing information [9]. FI students demonstrated the ability in solving problems better than FD students [10].

Gender in this study are the characteristics that distinguish between male and female are shaped by social and cultural factors and biologically formed. The results of research related to gender differences are very diverse [10]. In general, mathematics achievement of male better than the mathematics achievement of female [11],[12]. Hyde, Fennema, and Lamon expressed that male outperform female in terms of solving complex problems [13]. The research results of Awan [14] states that female students significantly have math self-concept more positive than male students. But contradict with the research results of Hergovich [12] that males showed higher self-concept in mathematics and females have higher self-concept in language. Therefore, in this study unique investigate the male-Field Independent (FI) student in order to present the description of adaptive reasoning and strategic competence in solving mathematical problem.

Adaptive Reasoning is mental activity to relate mathematical concepts, facts, procedures, and methods into mathematical problem situations so as produce an idea that used to solve mathematical problems. Mental activity in the reasoning adaptive can be observed through: mental activity to relate concepts into problem situations by explain logically their relationship; mental activity to select procedures and methods that appropriate with the situation problem by explaining logically the procedures and methods; mental activity to adapt between mathematical concepts, facts, procedures, and methods and the situation problem by justify logically [1],[3],[15],[16],[2].

Table 1. Adaptive Reasoning in Solving Mathematical Problem

Aspect	Sub-aspect	Sub-aspect observed
Explaining	Selecting concept	• Selecting appropriate mathematical concepts with problem situations

II. METHODOLOGY

This study employed qualitative research methods. The goal of the study was to present an accurate description of real situation regarding aspects of adaptive reasoning and strategic competence rather than simply asses mathematics expertise observed from the male-field independent (FI) student in solving mathematical problem. This subjek has a high mathematics achievement, that was known from given the test mathematics competence. This test arranged from nasional exam questions in 2013, 2014, and 2015 that have been converted into essay questions. Furthermore, subject also have been given GEFT (*Group Embedded Figures Test*) test to know that the subjek is field Independent student. This subject is eleventh grade student.

Since the aim of this study to examine the adaptive reasoning and strategic competence rather than simply asses mathematics expertise, it was necessary to supply a nonrutine problem that would challenge the student and was suitable for the study of adaptive reasoning and strategic competence. Nonrutine problem refer to a task that the student has not previously seen and done problem. The problem involve some mathematical concepts as settlement and need an efficient strategiy. The nonrutine problem given is as follows:

There is a land size $(200 \times 200)m^2$. Within the land there is a warehouse size $(40 \times 40)m^2$, which is located in center of one edge of the land and overlooking the land. The whole piece of land overgrown with greengrass and dense, except on the warehouse. An lawn mower has a cable length of 80 m. On the walls of the warehouse in right front corner there is an electricity source to turn on the lawn mower. Determine the area of land that allows the grass can be mowed?

Student were given nonrutine problem above and then interviewed in solving the mathematical problem. Subject was investigated to express his thingking regarding all aspects of adaptive reasoning and strategic competence in solving the problem.

To obtain credible data that what is observed in accordance with the fact that the credibility examination technique is done using triangulation of time. Examine the results of the interview data from a subject at different times. In addition, this research data partially obtained by using handycam and voice recorder and field note.

III. RESULTS

Next section discuss the contribution of this study on how adaptive reasoning and strategic competence in solving mathematical problem for male-field independent (FI) student. The following all aspects from adaptive reasoning and strategic competence are assembled into a logical steps in solving mathematical problem.

A. Selected strategy for understanding the problem

Subject understand the problem situation using a reading strategy then imagine it. Subjek spent approximately two minutes to understand the problem situation. Subject read the problem calmly without touching the sheet of problem stored on the table. Before the two minutes was up, the subject then smiled as he continued to read about it. This indicates that the subject read the questions and then imagine easily. After reading, the subject received the information and then formed a mental image. Subject looked sure have understood the problem situation.

B. Explaining and justifying strategy that had been selected

Subject explained and justified strategies that was used to understand the problem situation with confidence that the strategies was appropriate. Subject used reading strategy then imagined the problem situation to be able to know and see all information of the problem. The information consist the core and aim of the problems encountered. The core problem is something which is the base to arrive at a final solution. The aim of the problem is the direction on what to do. Thus, the subject could understand problem situation after going through the process of receiving information from a problem situation and then through the process of forming mental images so that they can see and know the essence of the problem and the aim. Subject justified reading and imagining strategies for understanding the problem situations because they were a common and the right way to direct what should be done.

C. How was the strategies used for formulating data/information is known and unknown from the problem situation

Subject formulated data was known and unknown from problem situation verbally. Subject disclosed information that was in a problem situation with recounted all the information of the situation using his own words without looking at the text of the problem. Each sentences were recounted by his own words to make image clearly. The situation of problem were understood than subject recounted by his own understanding. The subject also illustrates the situation with using paper as a land and his fingers as a warehouse.

D. Selecting appropriate mathematical concepts with problem situations and explaining the relationship of mathematical concept with the problem situation in understanding the problem situation

Initially, subject select concepts of square area and circle as concepts that appropriate with problem situations. Subject explained that land and warehouses has form square. The land was said to be square because the land has the size $(200 \times 200)m^2$. Which means that land has the same length is 200 m. Writing the size of square is “side multipled side”. As well as the warehouse also was said to be square because the warehouse has the size $(40 \times 40)m^2$that means has the same length is 40 m. The subject also explained that the concept of a circle has relationship with the problem because based from the problem situation that there was a lawn mower has a cable length of 80 m. Then will be found land area that allowed the grass cut by the lawnmower. Subjects used a pen then rotated one end and the other end have support on one point. Subject explained that if for example this pen is the cable length then land area that can be passed by the lawn mower is like this pen that is rotating in a circle with the electricity source as the center and the cable length as radius.

Subject explained that the electricity source as center point because the electricity source attached to the wall that can not be moved (fixed point). Then subject also explained that the cable length as radius because radius are connecting between the center to the edge or side of the circle. While the cable length is connecting between electricity source dan lawn mower, so that the lawn mower is limited mobility and can only in a circle.

E. Selecting methods as a solution

After understanding the problem situation, furthermore subject was asked to demonstrate how to solve the problem. Subject later imagine before drawing all the information received from the problem situation. At this stage of the representation of the problem situation, the subject has not immediately found the right solution. Initially, the first subject expressed will calculate the area of the warehouse first and then calculate the area of land overgrown with grass. After that, the land area is reduced to the warehouse area. Then, to calculate the area of land that grass can be cut by the lawn mower,and then subject drew a circle with radius of 80 meters with its center at the front corner of the warehouse. Subject sure that the grass inside a circle with a radius of 80 can be mowed by a lawn mower. The subject then make a new draw regarding all of the information contained in the problem situation. Subject drew only used a pen without using a drawing tool. Subject considered the size of the current drawing although not using the right scale.

F. How is the strategy used for representing problem situation that appropriate with method or concept selected and explaining strategy that has been used and explaining procedure

Figure 1. The subject's representation of problem situation

Subject was asked: *In what way you further solve this problem?* Subject make and produce a picture above (see figure 1). Subject representated the problem situation with make two square area, one are as a land with side length is 200 m and the other square as a warehouse with side length is 40 m . Subject also representated two circle, one circle with radius 80 m and the other circle with radius 40 m. Subject explained that circle with radius 80 m formed from the cable length. Circle with radius 40 m formed from remain of the cable length beyond the front wall of the warehouse with it's length 40 m, so that the length of remain is eighty minus forty equal forty meter and form a quarter circle with radius of 40 m. All part of the quarter circle exist in land area. Subject explained that the area of the land that it's grass allows mowed by lawn mower is composed of a half circle with radius 80 m, a quarter circle with radius 40 m, and an area that placed at right of the warehouse.

Subject were asked: *How your procedure to complete the area to look for*! Subject explained the procedure, first, calculate the area of a half circle with a radius of 80 m. Second, calculate the area of a quarter circle with radius of 40 m. Third, calculate the area of rectangular that it's sides 40 m multiplied by 80 m.

Furthermore, subject were asked*: How do you calculate the area of rectangular that it's sides 40 m multiplied by 80 m?* Subject think about 5 minutes. After that, subjek make a line that divides the that area so as form a right-angle triangle and a sector. Then make another high line in the area of sector as shown in figure 2.

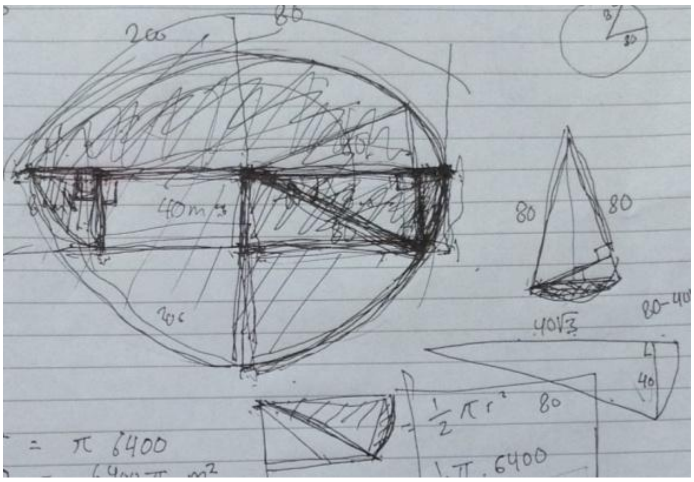

Figure 2. Student's Representation by Picture

G. Justifying strategy that have been used

Subject justify strategies used verbally and used of picture aids. His justification in accordance with the rules and properties concepts related . Subject divided the land area which allows the grass mowed by the lawn mower into four parts, namely a half circle with radius of 80 m, a quarter circle with radius 40 m, a one over twelve of the circle with radius 80 m and a right-angled triangle. Subjects were asked: *why do you say that this is a half circle*? Subject justified a half circle picture with the aid of picture that has been made. His justification was that "Due its center point is here (pointing to the center point of a circle with radius 80 m). Whereas here (pointing straight line to the left from the center to the circle line) 80 m and same here (pointing straight line to the right from the center to the circle line) is also 80 m and if we draw the line from here (center) to here (one point on the circle line so that the line is perpendicular to two line that have been mentioned earlier) in length is also 80 m. If we also use the tool for draw a circle with the center here (pointing to the center) will inevitably result in a half circle ". The subject asked again: Is There another explanation to justify it? Subject to re-explain that “if we draw a full circle, then this section (pointing a half-circle section with radius 80 m) is a half circle because, it's cleavage, forming diameter.”

H. How is the strategy for solving the problem

Subject was asked, "How do you solve this situation?", Then subject watched carefully the picture that has been made. Subject focused on each part of the picture that would be solved, even by separating the part of picture from the overall picture to be able solved the situation properly. Although drew that section separately repeatedly and took into account the size of the existing ones. After found the right solution, the subject later used a formula in accordance with the method used. Subjects completed the used of the formula to arrived at a final solution properly.

IV. DISCUSSION

Subject used strategies reading and imagining in understanding the problem. Subjects used strategies verbalize in formulating the problem situation. Subjects used the strategies imagining, symbolize and verbalize in representing the problem situation. Subject understood problem quickly because the subject managed to form mental images properly and appropriately. After imagined all the information captured from the problem situation, the subject admitted that he had understood the situation of the problem without have to draw these situations advance. Because obtain a good mental image of the problem situation, the subject feels confident that he has understood how the direction of what would has to be looked for and counted on the problem. The belief that the subject has really understood the problem, because the subject was able to retell a problem situation using their own language without seeing the text of the problem. Furthermore, subjects also immediately recognize quickly the concept that has the appropriate relationship with the problem, namely the concept of the circle. The subject was also familiar with other concepts quickly and appropriately during the process of solving problems. Subject provides an explanation of the relationship between the concept of a circle with a problem situation clearly. He explained all the parts of the circle associated with problem situations, such as radius, wide circle, center point, diameter, appropriately and in accordance with its nature. Subjects also justified the use of concepts and methods selected in conceptualization. From all that has been described above, it can be concluded that the subject has been linking "concept image" that has been owned by the understanding of the concepts that have been constructed since imange concept consists of "all of the mental pictures and associated properties and processes" [18]. For example, the subject explained that the cable length is appropriate with the nature of the radius because the radius connects the center point to the circle line while the cable length connects the electricity source with a maximum range of lawn mower. In addition, the subject explained that the electricity source is appropriate with the nature of the center point where the position settled at one point.

Overall, subjects correctly solve the problem until the final solution. The tendency of subjects complete the settlement procedures are analytically. For example, there is a part of the land area which also allows the grass mowed by the mower, as in figure 2. Subject analyze d this part first. And then the subject selected strategies to successfully find the wide of sector area. Based on that goal, the subject used drawing strategy three times with the size of each side in three different places. This shows that the subjects solve problems analytically. In accordance with the theory of cognitive style FI that the tendency of individual to use an analytical approach when processing information and goal oriented [5],[8] and capture the important parts of the information it received [9].

Subject provide explanations and justifications verbally and drawing on the concepts and methods used. Subject logically explain the relationship between concepts and problem situations. In accordance with the results of Holmes [8] that students FI has excellent logical reasoning. The subject also provides an explanation and justification clearly and always feel confident with his explanations and justifications. Students are confident because in every process through in solving the problem always use mathematical concepts, facts, procedures and method that appropriate. In accordance with the expression Kilpatrick [1] that the process of adaptive reasoning holds all the facts, concepts, procedures, and methods of mathematics to steer arrive at a right final solution. In addition, the subject was always sure and confident in solving the problem because according to the research results Hergovich [12] that boys have high math self concept.

V. CONCLUSIONS

This study focus to the aspects of adaptive reasoning and strategic competence from male-field independent (FI) student in solving the mathematical problem. Male-field independent (FI) student formulate the problem by revealing the data of known and unknown verbally. Understanding the problem situation by reading and imagining and without making a picture of the problem situation. Recognized the concepts that appropriate to problem situations quickly and precisely. Selected drawing method and then represented a problem situation by drawing all information that received and then create a symbol of mathematical formula. Explaining the relationship between concept and problem situations logically, complete and correct. Justifying the used of concepts and methods logically with full confidence. Male-FI student also solved problems right up until to the final solution of the problem completely.

The Characteristics Of Students' Refractive Thinkingabout Data

Anton Prayitno
Mathematics Education, The Faculty of Education, Universitas Wisnuwardhana Malang
arsedi2003@gmail.com

Abstract—Refraction is the process of produced the decision through reflection and critical thinking. Therefore, thinking that characterized by reflective thinking towards critical thinking until produce a decision called a refractive thinking. This shows that an important component of the refractive thinking is reflective thinking, critical thinking and a product. The reflective thinking is a process that occurs when a person encounters perplexity and conducted an investigation to find a solution. While, critical thinking is a process construct an alternative solution and evaluate various alternatives that can be considered to produce a decision. This study aimed to classifies the characteristics of students' refractive thinking about data. The approach used was a qualitative approach. The data source is the students of the 2nd semester by considering his communication skills. In this study, the students are required to complete the task and revealed with think a loud. If the student encounter reflective thinking and critical thinking in making decision, then students were included in the group of refractive thinking. The results showed that there were three characteristics of the refractive thinking performed by the students, namely: (1) the refractive thinking with a single strategy, (2) the refractive thinking with a dual strategy, and (3) the refractive thinking with multi strategies

Keywords:*refractive thinking, reflective thinking, critical thinking, data*

I. INTRODUCTION

Data considered as "number" [1]. In this case, data is not viewed as information on the specific situation about decision. Consequently, students always using statistical procedures to solve it, such as count the average or sum without attention of context provided. This proved with research [2] that some students in processing data by means comparing average or sum in making decisions about "most favored of cafeteria food". Some phases of completion to avoid misleading, among other: interpretation, description, conjecture, explanation and evaluation [2]. In view of [3] and [4] that descriptions and interpretation developed by [2] is the phase of reflective thinking. In the other, [5] and [6] identified that conjecture, explanation and evaluation are phase of critical thinking. Thus the phase of completion developed by [2] consists of two processes, namely reflective thinking and critical thinking. [7] and [8] defines that process produce a decision through reflection and critical thinking called refraction. Therefore, thinking that characterized by reflective thinking towards critical thinking until produce a decision called a refractive thinking. This indicates that a important component of refractive thinking is reflective thinking, critical thinking and decision.

Reflective thinking is one of the important thought process in construct knowledge and experience. The reflective thinking signed with difficulty (trouble) experienced by person so that he/she doing continuously behavior changes. Behavior changes are the process of investigated with explore information on the problem [9]. Investigations done to resolve the situation of uncertainty, instability, uniqueness, and conflict so that as provide answers the questions [9]. Reflective thinking occurs because of process connected one's knowledge with new information. This is matching with opinion of [3] and [10] that reflective thinking is process take knowledge and experience it then used to resolve problem. Reflective thinking is process occurs when person experienced perplexity and doing investigation repeatedly until finds completion [11]; [12]; [13]; and [14]. Perplexity are uncertainties or difficulties when solving problems. Inquiry is activity repeatedly searching for information that leads to settlement the problem. Reflective thinking has important role, namely as tool someone to solve the problem. With the thinking, can provide an opportunity for someone to step back and think about the best strategy to achieve goal [15] and [16]. Thus, reflective thinking is very important because it can help develop strategies and apply new knowledge the complex

ISBN 978-602-74529-0-9

situations. If reflective thinking done right, then help person to next step which called critical thinking [7] and [8].

Be related with critical thinking, [7] that critical thinking signed with process of evaluated a variety of relevant information when doing reflection in the problem solving. Implicitly "evaluation" revealed [7] is process of selected alternative solution obtained thus be taken consideration to decision making. It shows that decision must based on relevant information or attributes the problem. This is mismatch with the opinion [17]; [18] and [5] that critical thinking is process of considering and evaluating of some information obtained so that possible to decision making. Critical thinking signed with activity interpretation and evaluation of the problem solving[18]. Interpretation revealed the definition is process construct some settlement and produce an alternative solution. Moreover, the word "evaluation" is process of determining some-thing. Evaluation is a process signed with selected solution or best answer from some alternatives [5].

Some researchers have review the reflective thinking as process towards critical thinking, among others: reflective thinking is the one tool to develop higher-level thinking [19]; critical thinking is the result of one's reflection in learning [20]; reflective thinking to support critical thinking skills in solving social and political problems [21]; reflective thinking increases one's critical thinking and understanding which learned [22]; reflective thinking the beginning of the process of critical thinking specifically refers to the process of analyzing and making judgments [23] and [24]; Reflective thinking is the key of critical thinking [23]. In the study, [2] showed the students experienced when using phase shift in thinking reflective thinking and critical thinking so as to produce variations of the model answers. However[2] did not review how the thinking of students in produce the answer. Whereas [7] write a study of refraction theoretically and not review in the mathematics education. In the research have not provided description about how process of reflective thinking continued to critical thinking till produce decisions. Therefore this article review the process of reflective thinking towards critical thinking till produce decisions called as refractive thinking

II. LITERATUR REVIEW

A. Definition of Refractive Thinking

Using a metaphor light to describe the refraction [25]. Refraction is process light hit a medium thus result reaction which triggered the refraction of light towards a certain point. Based on the metaphor, [7] and [8] states that the refraction occurs because of the reflection continued critical thinking and produce new knowledge. Therefore thinking is signed with reflective thinking continued critical thinking till produce decision called refractive thinking. This indicates that an important component of refractive thinking is reflective thinking, critical thinking and decision (product). The process of refractive thinking can be illustrated in Fig 1.

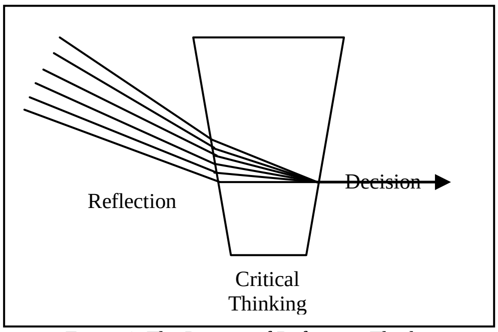

Figure 1. The Process of Refractive Thinking

Based on the illustration, process of refractive thinking occurs because of the process reflective thinking continued critical thinking until produce decision. This indicates that important component refractive thinking is reflective thinking, critical thinking and decision. The refraction is the transformative knowledge that occurs the which validates the use of critical analysis and problem solving providing interpretation and Conclusions of important issues and situations considering the course content and context [7]. Knowledge transformative in this case is ability of person resolve problems through some alternative solution. The purpose of refraction is process decision-making by considering some possible alternative solution. This shows that the refraction is focusing of information since there are some alternative solution obtained when reflection and do critically analysis as consideration to establish a decision. Be related with refraction, [8] defined that refraction is new knowledge acquisition from critical thinking of reflection. This shows that the refraction is the process of acquiring new knowledge (decision) resulting from reflection and critical thinking. Therefore refractive thinking this study is process of decision making through reflective thinking continued with critical thinking

B. Reflective Thinking

Basically, component of reflective thinking implicitly contained in the notion of reflective thinking. To make component ofreflective thinking determined beforehand some notion of reflective thinking of some of the views. The reflective thinking is a process occurs when someone experiencing perplexity and then conducting an inquiry repeatedly until find the solution [11]; [12]; [13] and [14]. Based on some notion reflective thinking, implicitly important component of reflective thinking namely perplexity and investigation.

Reflective thinking is initiated by the perception of something troubling or promising, and it is determined by the production of changes one finds on the whole satisfactory or by the discovery of new features which give the situation new meaning and change the nature of questions to be explored [9]. This shows that, reflective thinking signed with difficulty (trouble) experienced byperson so that he doing continuously behavior changes. Behavior changes are the process of investigated with explore information on the problem. Investigations done to resolve the situation of uncertainty, instability, uniqueness, and conflict so that as provide answers the questions. Based on the above definition reflective thinking, implicitly there are some components of reflective thinking. Components of reflective thinking according to [11]is perplexity and inquiry. According to [9] is the trouble and experiment. Two opinions can be compared. The equality of reflective thinking [11] and [9] presented in Table 1 below. Implicitly, Based on the similarities in the nature of each component, the obtained result of the development of reflective thinking in this article.

Table 1. Development of Reflective Thinking

[11]	[9]	[26]
Perplexity Uncertainty about something that is difficult to understand.	*Trouble* Difficulties experienced by someone	*Perplexity* Difficulties experienced person to continue the next process; doubts about the answer or solution is found or confusion when someone obtained unexpected results
Inquiry The process of repeatedly information that directs the mind to a certain direction.	*Experiment* Investigations conducted by exploring information to obtain an idea to solve the problem..	*Investigation* An investigation by exploiting existing knowledge to look back information or settlement process because of a uncertainty or doubts in obtaining answers

The table 1 shows a comparison of reflective thinking [11] and [9], namely: (1) Trouble partial indicator illustrated also in perplexity, such as someone difficulty in problem solving. Perplexity developed by Dewey is not just in trouble, but rather confirms the existence of doubt or lack of confidence their completion. If students are having trouble, doubt or confusion in solving the problem then it is said the students experienced perplexity; (2) Inquiry can be compared with the experiment, because the inquiry has the same properties as the problem that is causing the effort provide a solution. In the process of looking at the problem, a person can remember what you learned and utilized to solve the problem. The process is known as behavioral changes. In other words, students conduct an investigation by leveraging existing knowledge to look back the settlement process due to a lack of confidence or doubt in obtaining answers. Students who experience the process said investigation.Therefore reflective thinking in this article is the thinking process that signed the perplexity and then conducted an investigation till find a solution to the problem [26].

C. Critical Thinking

Critical thinking component is implicitly contained in the definition of critical thinking. To create a critical thinking component is determined in advance some notion of critical thinking of some of the views. [7] argued about critical thinking, Critical thinking demonstrates the ability to evaluate relevant information and opinions gathered in the reflection stage in a systematic, purposeful, efficient manner developing problem solving skills. This shows that evolution occurs because of the reflection of someone in solving problems. Thus the "Evaluate relevant information and opinions gathered in the reflection stage" which is revealed in the definition explicitly states that the evaluation and collection of some of the information is a component of critical thinking.

Be related critical thinking, [18] states that critical thinking is skilled and active interpretation and evaluation of observation and communication, information and argumentation. Critical thinking by [18] signed with interpretation and evaluation of information and statements. Usually Interpretation is construct and produce some solutions alternative. this is case, beginning to conclusions from problem. In addition, evaluation is process of determined something. Evaluation signed with selecting the most excellent of some alternatives [5].Based above definition critical thinking, implicitly there are some components of critical thinking. Components of critical thinking according to [18]interpretation and evaluation. According to [7] is Opinions gatheredand evaluation.Implicitly, Based on the similarities in the nature of each component, the obtained result of the development of critical thinking in this article.

Table 2. Development of Critical Thinking

[18]	[7]	[27]
Interpretation Construct some solutions and produce some alternative	*Opinionsgathered* Produce alternative possibility settlement obtained from some of the information collected	*The constructive activity* Constructing an alternative solution that leads to the answers or construction compare alternative
Evaluation Select the best of some alternatives	*Evaluation* The process of evaluating some alternatives settlement.	*Evaluation* evaluate settlement alternatives and answers the result by considering the relevant information.

The table 2 shows a comparison of critical thinking [18] and [7], namely: (1) Gathered opinions can be compared with the interpretation, because it has the same properties that produce alternative possibilities completion. The possibility of constructing an alternative solution requires a variety of information that has been collected in the process of reflection. The situation is known as construction (construct); (2) Evaluation of critical thinking [7] and [18] can be compared as in selecting or evaluating an alternative solution or answer. This component signed by evaluated alternative solution or answer based considerations. This component is known evaluation.Therefore critical thinking in this article is thinking process that signed the construct and evaluation alternative settlement and the best answer based on various considerations [26].

III. RESEARCH METHODS

The purpose of this study was to explored and classified the processes of students refractive thinking in solving mathematics problems. Refractive thinking indicated from the process of students construction against instrument task "decision-making". This study used a qualitative approach, since according to characteristics owned. The research was carried on students in 2nd semester. For this purpose, the research took the data on student at Universitas Wisnuwardhana Malang and Universitas Negeri Malang. Research subjects not randomly selected, However taken with considered his communication skills so disclosure of the thinking process can be done well.

In this study, students were asked to complete task and expresses out loud what he was thinking (Think Out loud) when solving problem. After students obtain settlement, research check the students process settlement correct to obtain answers. If student experience reflective thinking and critical thinking in produced decision, then student will be a subject and included in the group refractive thinking. Each group is filled by two research subjects. If not obtain the desired subject, then the given the task again to students. The process of selecting subjects performed until a saturation of the data, its meaning that appears the same or remain characteristics of some subjects for each category. The many research subjects for each reflective thinking is 2 subject. Determined 2 subjects, with consideration that the method analysis used the constant comparative method. The task sheet instrument "decision making" used in this research is the development of a decision-making instrument from [2]. Problems in this article are influenced by quantity and quality that is large and increase of numbers each object. The problem given to the students as follows.

Local Revenue Officessurvey 6 district to find out the level of district dependence on the central government. The dependence of regional on the central government can be measured based contribution the Own-Source Revenue (OSR) to income of province. If the contribution of OSR greater and increasedthen the district dependence to central government is getting low. The value in table below shows the percentage contribution of OSR to income of province based Natural Resources (NR) for three years.

NR \ District	A			B			C			D			E			F		
	Th. 1	Th. 2	Th. 3	Th. 1	Th. 2	Th. 3	Th. 1	Th. 2	Th. 3	Th. 1	Th. 2	Th. 3	Th. 1	Th. 2	Th. 3	Th. 1	Th. 2	Th. 3
livestock	*19*	*9*	*19*	*12*	*24*	*15*	*14*	*22*	*17*	*23*	*14*	*23*	*21*	*15*	*14*	*11*	*16*	*12*
Maritime	*18*	*20*	*13*	*9*	*19*	*19*	*12*	*23*	*17*	*24*	*8*	*8*	*19*	*12*	*19*	*18*	*18*	*24*
Forestry	*20*	*15*	*19*	*13*	*18*	*18*	*17*	*19*	*15*	*23*	*13*	*11*	*18*	*18*	*10*	*9*	*17*	*27*
Plantation	*9*	*11*	*26*	*23*	*17*	*14*	*20*	*22*	*15*	*17*	*16*	*14*	*16*	*24*	*15*	*15*	*10*	*16*
Agriculture	*25*	*14*	*20*	*14*	*13*	*15*	*19*	*15*	*24*	*16*	*24*	*14*	*16*	*18*	*9*	*10*	*16*	*18*
Fishery	*12*	*23*	*8*	*19*	*14*	*24*	*7*	*13*	*9*	*15*	*16*	*21*	*24*	*9*	*23*	*23*	*25*	*15*

The brother task is determine the order of district from the lowest to the highest dependence on the central government! Give an explanation for your answer!

Figure 2. Instruments Task

IV. RESULTS AND DISCUSSION

In this article the author only describes refractive thinking 3 subject. Third of subject were grouped into three groups: group one is subject 1 (S1) called single strategy. Subjects were included in the group 2 is subject 2 (S2) called dual strategy. Subject were included in the group 3 is subject 3 (S3) called multi strategy.

A. Characteristics of Refractive Thinking With Single Strategy by Subject 1 (S1)

The process of refractive thinking, begins with perplexity S1 to settlement. S1 determine average of each district. Settlement by average used as strategy to determine order of district. S1 think that the settlement with average can be used solved to problem. In the process look for average, S1 describes problem into some parts. S1 completed the first district A, B until the F. Thus overall average of district is the same, i.e. 16,7%. S1 questioned again the average obtained is the same "evidently of average the same?". S1 suspect that the strategy has not been to solved the problem. S1 reading again problems and silent for long time. In this case S1 experienced reflective thinking [11] and [9]. S1 questioned "if the great contribution and increase then low dependence, how do it?". This show that S1 experience perplexity again when obtained average of the same. S1 think long time again and suspect of criteria "if the greater and increase contribution of Natural Resources then the district dependence to centre of lower".

Based on these criteria, then S1 used another settlement with summing the percentage of contribution per year. The process is due to determine the amount of contributions per year. This shows that, when S1 suspect that strategy cannot be used to solve problems, he tried another strategy to solve it. This shows, S1 experience a process of critical thinking [7] and [18]. S1 summing percentage contribution per year. To explore the thinking process of S1 when solved with sum the percentage contributions per year, the research performed interviews. S1 claimed that to determine order of the district, the first of summing contribution per year. The settlement is based on the criteria of "substantial revenue contribution and increased". To determine the order of the district, the first S1 determine the great of contribution then compared with other district to determine the decrease and increase of contribution every year. The following settlement by summed the percentage contribution per year done by S1.

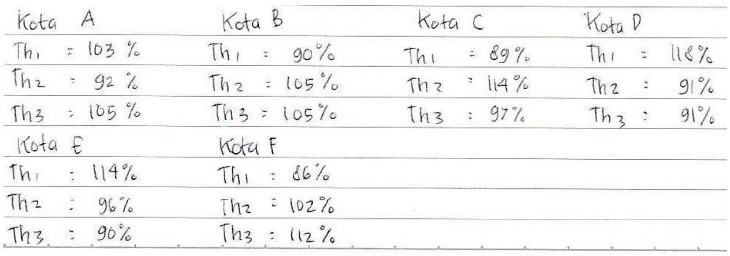

Figure 3. The result of students' (S1) work about summed the percentage contribution summed the percentage contribution

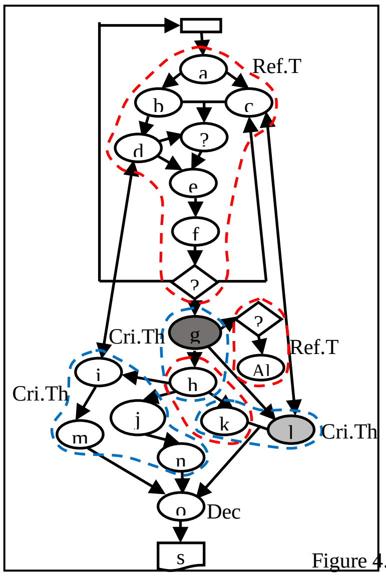
Process doing by S1 is grouping district of each year. S1 again shows the relations criteria "increase" with the amount of contribution each year "the great contribution and increased ..". The statement S1 aware that the criteria "increase" is the keyword to determine the order of the district. Implicitly, S1 can determine relations of the increase and dependency. S1 judging that the district has increased every year is district with low dependence while the district has decreased is an district with a high dependency.

ISBN 978-602-74529-0-9

The next process, S1 experience critical thinking with identifying and comparing each district which has increased of contribution each year. Based on the amount of contributions obtained, S1 indicates the lowest dependence is district F. The process done with compared the district F and other district. F are considered to have significant increases each year. The next process second order. In the second order, S1 connect again and compared the increase in the amount of the contribution of each district. Based on the amount of contributions obtained, S1 shows second order of lowest dependence of district is the B. if compared with other district, District B has increase in the third year despite constant.In the determine third order, S1 distrustful is district A and C. S1 compared the great of contribution and the increase in district A and C. The district A occur decrease from the first year to the second year, then increase in the third year. The district C occur increase from the first to third year and then decreased in the third year. In the selection for third order, S1 experienced perplexity. S1 think again with to give an alternative settlement to indicate the difference between A and C. In the first year of district A is 103%, while district C is 89%, this indicates that the district A was excelled in the first year. While the second year, district A is 92% and C is 114%, this indicates that the district C was excelled. In the third year, district A was excelled as 105%, while district C is 97%, this indicates that the district A has a large amount of contributions for two years, while C is only one year. The next process is fourth sequences. S1 put district C as fourth sequences. District C is the comparator A when determining third order, however the district A was excelled compared to district C. Based on these, S1 puts district C as the fourth order. In addition, S1 was connected and compared the increase amount of contribution each district. If district C was compared to other regions (areas D and E), then district C was increased. In the fifth and sixth sequences , S1 only compared the two district that have not been occupied the previous sequence, i.e. D and E. The District D has decreased but the fixed in the third year. District E has decreased the amount of contribution significantly, that is the first year until third year in a row by 114%, 96% and 90%. District D as district that occupies the fifth order because amount of contribution the same that is second and third year is 91%. This shows that in the second year and third year, district D does not decrease (constant). Based on settlement process do by S1 in making decision about district sequence begin lowest to highest of dependence i.e. district F, B, A, C, D , and E. Conclusions are based on the criteria of "amount of great contributions and increased"

With these answers, S1 believes the answer. In the process of decision making, a subject need only one settlement alternative. Subject only to clarify the criteria contained in the problem as consideration to decide, for example, to identify the contribution of each year. Based on the thinking, S1 experienced refractive thinking with single strategy. The refractive thinking process by S1 can be illustrated in Fig. 4 below.



a	:	Sort district based on dependency
b	:	Contribution of NR increased every year
c	:	Lowest of dependency
e	:	The average contribution per year in each district
f	:	The result is the same
g	:	Summed contributions per year
h	:	Summing contributions every district
i	:	The amount of contributions increased

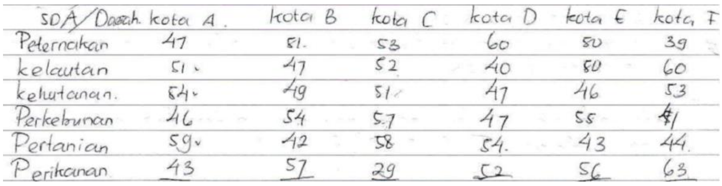
Figure 4. The Refractive Thinking With Single Strategy by S1

B. Characteristics of Refractive Thinking With Dual Strategy by Subject 2 (S2)

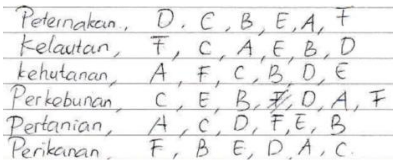
In the process of thinking, appears that S2 have difficulties to solve problem. S2 solved with summed the percentage contribution of each district based Natural Resources (NR). The process called analytical process, which is a process that describes the problem into several parts so that the parts are then completed. The summing is done by S2 begins by calculating the percentage contribution of livestock. S2 summing the percentage contribution of the farm for three years in each area. This process is carried out from the district A to district F.



SDA/Daerah	kota A	kota B	kota C	kota D	kota E	kota F
Peternakan	47	51.	53	60	50	39
kelautan	51	47	52	40	50	60
kehutanan.	54	49	51	47	46	53
Perkebunan	46	54	57	47	55	41
Pertanian	59	42	58	54.	43	44.
Perikanan	43	57	29	52	56	63

Figure 5. The result of students' (S2) work about summing percentage contribution of the farm for three years in each area

The District order first on the livestock is district D, C, B, E, A and F. This is because the amount of district contribution to livestock the greatest is district D i.e. 60, then district C is 53 and smallest amount is district F i.e. 39. While in maritime, district F is a district order first because it has the highest amount of contributions compared to other district i.e. 60. Then continue district C with contribution amount 52 and district last order is district D with contribution 40. The group process and sorted performed by S2 until fishery.



Peternakan, D, C, B, E, A, F
Kelautan, F, C, A, E, B, D
kehutanan, A, F, C, B, D, E
Perkebunan, C, E, B, ~~F~~, D, A, F
Pertanian, A, C, D, F, E, B
Perikanan. F, B E, D, A, C.

Figure 6. The result of students' (S2) work the group process and sorted until fishery

The next process, S2 combines the sequence a whole. In the process of combining sequences, S2 connects sequence with rank . It can be seen from the statement S2 ".... makes the rank first, A, B, C, D, E, F, and rank 1, 2, 3, 4, 5, 6". This indicates that S2 experience process of critical thinking[7] and [18].The statement indicates that the S2 explicitly show relationship of district with ranking. S2 connected ranking with district have greatest to smallest of contribution amount at each Natural Resources.

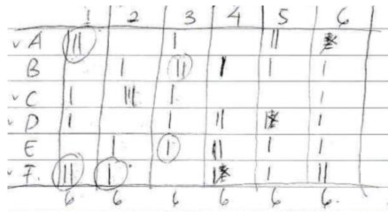


Figure 7. The result of students' (S2) work about connected ranking with district

Based on above settlement, S2 attention district that are above (first order). The first sequence of the district there are four choices of district A, C, D, and F. S2 connected one district to other district of sequence, in this case S2 compared district A, C, D, and F. Based on this comparing, many district (mode) the first sequence is same. District mode C and D is one, while district A and F is two. S2 compared A and F with sequence thereafter (second). In sequence afterward (second), mode of district F is one, while areas A no mode. S2 identify the sequence thereafter (the second) for consideration determining the first sequence. S2 choose F as district in first sequence, while A is chosen as district in the second. This is because the district A ranks first as much two and rank second as much three.The next process is third order. To determine the sequence of third, S2 compare district B, C, D and E. Based on four district, S2 comparing many district in the first sequence. In the first sequence that appears only district C and D as many one. Furthermore, S2 consider the order after namely the order of two and three.The next process is fifth. S2 looked back at remaining district, namely B and E. S2 connects the district B and E based on the second and third sequence. In the second sequence, district B as much one, while E as much one. Shows that the district have same mode in second order. S2 choose alternative of compared that is third sequence. District B in third order as much 2 while district E only 1. Based on settlement process, S2 make decisions about sequence from lowest to highest dependence on district F, A, C, D, B, and E. Conclusions are based on compared many district (mode) in certain sequence. The process of refractive thinking with dual strategy by S2 can be illustrated in Fig. 8 below.

Figure 8. The Process of Refractive Thinking With Dual Strategy by S2

C. *Characteristics of Refractive Thinking With Multi Strategy by Subject 3 (S3)*

S3 represents contribution of the most widely with summed percentage contributions for three years. S3 added the percentage of each district from first to the third year on each Natural Resources
S3 using another settlement which connects with the sequence of points or score. The biggest scores indicate low dependence, whereas the lowest score showed high dependency. The first sequence district were the biggest scores, while the last order district was lowest score. S3 gives a score of 6, while final sequence given score of 1. This indicates that S3 integrates sequences with the scoring. The following settlement by S3 relating to the scoring.

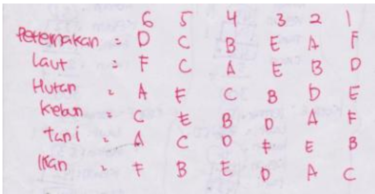

Figure 9. The result of students' (S3) about relating to the scoring

The next process, S3 summed scores each district. For example, the score of district A is 6,6,4,2,2,2 if the scores are summed obtained 22. The process of scores summed in each district until district F. The following results of work by S3 related to total score of each district.

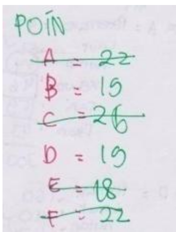

Figure 10. The result of students' (S3) about total score of each district

Based on the results work above, the lowest order first is district C. chosen C as the lowest order first by S3 because of some district, the district C has greatest amount of scores. This is consistent with previous statement by S3 *"The greatest contribution is the most low dependence"*. S3 feel confident with the first order is district C. This appears statement by S3 *"means the correct .."* The next process of the second order. S3 attention again the total score of each district. Based on the results work are district have the same amount in the second i.e. the district A and F. The total score of two is 22. This indicates that possibility of a second sequence is occupied by A and F, the following statement S3 *"A and F, here the twins, second chances if not A, yes F ".*

Based on the similarity score on A and F, S3 silent for moment and reading again the question. S3 experience perplexity in determine the order of second. The behavior appears with statement S3 "Then I see from where?.. we see from here highest (pointing Natural Resources) ". To determine the order of second, S3 consider many Natural Resources with a amount great contribution in A and F. District A, the Natural Resources has large amount is 4 (livestock, forestry, plantation and agriculture), while district F is 2 (maritime and fisheries). This shows that A has greater Natural Resources to contribute of district F. The following results of work by S3 related to many Natural Resources.

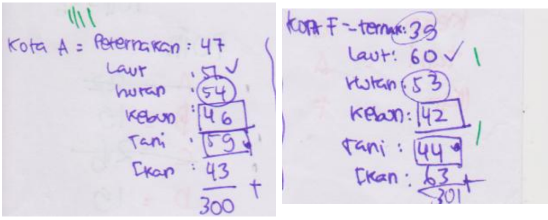

Figure 11. The result of students' (S3) about related to many Natural Resources

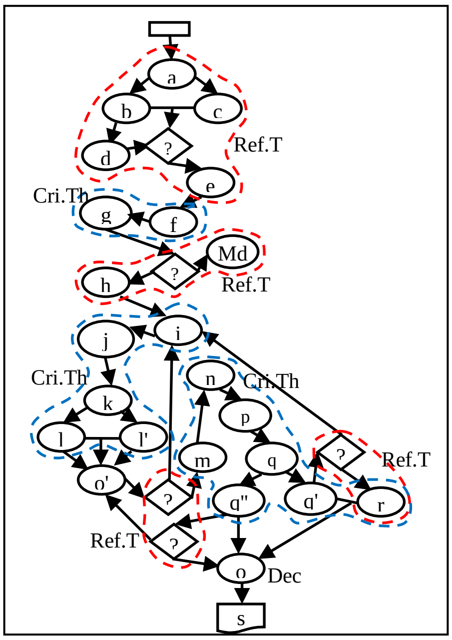
Based on the results work, then the second order and third is district A and F. This is because district A has more natural resources compare the district F. With these answers, S3 believes the answer. In the process of decision making, subject not only requires two strategies (addition and ranking), but he made another settlement (score) as reinforcement for answers obtained. Based on the thinking, S3 experience refractive thinking with multi strategy. The process of refractive thinking with multi strategy by S3 can be illustrated in Fig. 12 below.



a	:	Sort district based on dependency
b	:	The largest of contribution
c	:	Lowest of dependency
f	:	Summed contribution per sector in each district
g	:	Summed contribution of each district as a whole
d	:	Remember

Figure 12. The Process of Refractive Thinking With Multi Strategy by S3

V. CONCLUTION

From the results study to refractive thinking of students in solving mathematics problems can be concluded that there are three type processes of refractive thinking by students, namely: (1) refractive thinking with single strategy signed the process of decision making, a subject need only one settlement alternative. Subject only to clarify the criteria contained in a problem of consideration to decide, for example, to identify the contribution of each year, (2) refractive thinking with dual strategy signed the process of decision making, the subject need two alternatives. If there are sequence of district the same, subject uses internal comparison as consideration, for example considering the mode of sequence before and after, and (3) Refractive thinking with multi strategy with the process of decision making, subject need the settlement of three alternatives. If there are sequence of district the same, subject uses external comparison as considerations, for example identified many Natural resources with largest amount.

Effectiveness Of TPS And SGD With Scientific Approach In Terms Of Problem-Solving And Self-Confidence

Anwar Rifa'i[1], Himmawati Puji Lestari[2]
[1,2] Department of mathematics education, Yogyakarta State University
anwar.rifaai@gmail.com

Abstract-This study aimed to know the effectiveness of Think Pair Share (TPS) and Spontaneous Group Discussion (SGD) with scientific approach in terms of problem-solving and self-confidence. This study was quasi-experimental with pre-test post-test nonequivalent group design. The population consists of 101 students in grade X MIA MAN 1 Yogyakarta. Its samples were 34 students of X MIA class who gets TPS with scientific approach and 33 students of X MIA 2 class who gets SGD with scientific approach. The instruments were test instrument to measure problem-solving and non-test instrument which consists of scale to measure self-confidence and observation sheet to observe learning process. The results of this study with a significance level $\alpha = 0.05$ were : (1) The first experiment class problem-solving significant value is 0.000, therefore TPS with scientific approach is effective in terms of problem-solving. (2) The first experiment class self-confidence significant value is 0.006, therefore TPS with scientific approach is effective in terms of self-confidence. (3) The second experiment class problem-solving significant value is 0.000, therefore SGD with scientific approach is effective in terms of problem-solving. (4) The second experiment class self-confidence significant value is 0.039, therefore SGD with scientific approach is effective in terms of self-confidence, (5) Significant value of problem-solving comparison is 0.048, therefore TPS with scientific approach is more effective than SGD with scientific approach in terms of problem-solving. (6) Significant value of self-confidence comparison is 0.882, therefore TPS with scientific approach is as effective as SGD with scientific approach in terms of self-confidence.

Keywords:*self-confidence, problem-solving, scientific approach, TPS, SGD*

I. INTRODUCTION

Science and technology continue to evolve in line with the developments of education. Education consistently develops the potential of the next generation in order to become good human resources. These human resources will gradually create new discoveries which are important for human life. In Indonesia, the importance of a education role is conceived by designing the function and purpose of education [21] written on UU No. 20 of 2003. As an effort to achieve the goal, curriculum was created. The latest curriculum is Curriculum 2013. Curriculum 2013 is focused on character, knowledge, and skill [9]. Curriculum 2013 expects students not to only have a high ability but also cognitive skills and a good attitude or character.

In this curriculum, mathematics is one of the subjects that must be learned by the students. It is because mathematics helps people in developing the technology and science. According to Branca [2] problem solving is the heart of the mathematics. The consequence is students should learn this ability. The problems which are used to train students' problem solving ability must fulfill two criterias. According Herman Hujodo [5], the criterias are (1) the question should be understood by students but it is still a challenge for them. (2) The question can't be done by routine steps of problem solving. There are two kinds of problems which are problem to solve and problem to find [18]. In this study, type of the problem is problem to find. Problem solving expects students to follow a series of steps to find a solution. According to Polya [17] the series of steps are understanding, planning, problem solving, and rechecking.

Based on the Curriculum 2013 [9], standard graduation of attitude aspects are faith, nobility, self-confidence, and responsibility in interacting with social and natural environment. Based on this statement, it is known that self-confidence is very important. According to Lauster [10] self-confidence is an attitude or belief in self-ability so that the actions are not too anxious, feel free to do things as you wish and be responsible for his actions, be polite in their interaction with others, have the drive to recognize the achievements and the advantages and disadvantages. Self-confidence will lead people to achieve their success. In this study, aspects of self-confidence are belief in self-ability, internal locus of control, objective, responsibility, rational and realistic.

There is indication that students' problem solving ability and self-confidence in Madrasah Aliyah (MA) is not optimal. It is caused by the study load in MA is heavier than common high school. In MA, students not only study about common materials like in formal school but also materials about religion [8]. According to Slameto [16], the study load is one of the reason of the difficulty in learning including problem solving ability and self-confidence. This condition is agreed by student of MAN 1 Yogyakarta. They do not understand well the material because of the study load.

Based on the Regulation of the Ministry of Education and Culture No. 65 year 2013 [12] about the Standard Process, it is stated that the standard of learning in the Curriculum 2013 is using a scientific approach, integrated thematic, and thematic. Scientific approach is choosen to deliver mathematics concept. This approach adopts constructivism in which students are required to build their own knowledge. According to Daryanto [1] the scientific approach is a learning process that leads students to actively develop principles, concepts or laws through scientific steps. These steps are outlined in Regulation of the Ministry of Education and Culture number 81 A 2013 annex IV [13] and Regulation of the Ministry of Education and Culture number 103 2014 [14] which consist of: observing, asking, gathering information, associating and communicating. Thus, scientific approach will assist students in learning mathematics

There are many learning models which have been developed by experts. One of learning models is cooperative learning. According to Spencer Kagan & Miguel Kagan [7] cooperative learning is the most effective model to achieve the learning's goal. Cooperative learning has also been developed by experts so that there are many types of cooperative learning. Those types include Think Pair Shre (TPS) model and Spontaneous Group Discussion (SGD)

TPS learning models lead students to solve the problem following three steps. Those steps are think, pair, and share. TPS learning model helps the students to solve the problem individually before they discuss in pairs and present the discussion result. This condition improves students' problem solving ablility. According to Fogarty dan Robin [1] TPS learning model trains students to be brave in sharing their idea in front of the class.

SGD learning model leads students to solve the problem following three steps. The steps are grouping spontaneously and variously, discussing the problem, and presenting their discussion's result as the teacher calls each groups [11]. Conducting SGD learning model is easy because its learning process is simple. The discussion which had been done by five students allowed students to share their ideas each other to solve the problems. SGD learning model has also step of calling all group to present their discussion's result. It will improve students' self-confidence.

There is a consideration that TPS and SGD learning model combined with scientific approach can improve students' problem solving ability and self-confidence. TPS learning model combined with scientific approach leads students to solve the problem following steps of scientific approach in group using TPS model, therefore in the end of learning they discover a new concept of matehmatics. SGD learning model combined with scientific approach leads students to solve the problem following steps of scientific that is conducted trivially and spontaneously.

Based on the description above and the potential of the steps in TPS and SGD model combined with scientific approach, it is necessary to conduct a research about the effectiveness of TPS and SGD learning model combined with scientific approach in term of problem solving ability and self-confidence in MAN 1 Yogyakarta.

The problems in this study are described as follows: (1) Is the TPS learning model combined with scientific approach effective in terms of problem solving?, (2) Is the TPS learning model combined with scientific approach effective in terms of self-confidence?, (3) Is the SGD learning model combined with scientific approach effective in terms of problem solving?, (4) Is the SGD learning model combined with scientific approach effective in terms of self-confidence?, (5) Which is more effective between the TPS learning model combined with scientific approach and SGD learning model combined with scientific approach in terms of problem solving?, (6) Which is more effective between the TPS learning model combined with scientific approach and SGD learning model combined with scientific approach in terms of self-confidence?

The purpose of this study are: (1) to describe the effectiveness of TPS combined with scientific approach in terms of problem solving abilities, (2) to describe the effectiveness of TPS combined with scientific approach in terms of self-confidence, (3) to describe the effectiveness of SGD combined with scientific approach in terms of problem solving abilities, (4) to describe the effectiveness of SGD combined with scientific approach in terms of self-confidence, (5) to describe which one is more effective between TPS combined with scientific approaches and SGD combined with scientific approach in terms of problem solving, (6) to describe which one is more effective between TPS combined with scientific approaches and SGD combined with scientific approach in terms of self-confidence.

The benefits of this study for the teachers are (1) getting alternative of learning models to apply the scientific approach, (2) getting reference to improve students' problem solving ability and self-confidence, (3) helping the teacher in conducting an interactive and effective mathematics learning. The benefits of study for students are: (1) students are able to improve their ability in problem solving, (2) students are able to improve their self-confidence, (3) students are able to improve thir ability in sharing their idea.The benefits of this study for researchers is getting direct experience of the researcher as a potential educator in implementing the learning model and its influence in terms of problem solving and students' self-confidence

II. METHOD

This research was a quasi-experimental research, a study used to estimate the causal impact of an intervention on its target population. This study was conducted at MAN 1 Yogyakarta, Indonesia, in the first semester of academic year 2015/2016. The material in this study was Sequence and Series. All students in grade X MIA MAN 1 Yogyakarta which consists of 101 students is used as population. The sample consists of two classes which had been chosen randomly with cluster random design. First experiment class was X MIA 3 which consists of 34 students and the second experiment class was X MIA 2 which consists of 33 students. This study used three variables: independent variables, dependent variables, and control variables. The independent variables were cooperative learning model with two variations types; they were Think Pair Share (TPS) learning model and Spontaneous Group Discussion (SGD) learning model. Both of types were combined with scientific approach. The dependent variables in this study were problem solving ability and students' self-confidence. The control variables in this study were allocation time of learning process, the teacher, and sequence and series material.

The research design which was used in this study was pre-test post-test non-equivalent group design. This design was presented in the following table.

TABLE1. RESEARCH DESIGN

First experiment class (E_1)	*Pretest*	TPS combined with scientific approach	*Posttest*
	Scale		Scale
Second experiment class (E_2)	*Pretest*	SGD combined with scientific approach	*Posttest*
	Scale		Scale

Non-test and test instrument were used in this study. The test instrument consisted of pre-test and post-test, each of them consisted of four items. Test instruments were used to measure students' problem solving ability before and after the treatment. Non-test instrument consisted of a scale of self-confidence and observation sheets. The scales were given before and after treatment to measure students' self-confidence. Observation sheets were used to observe and record the implementation of the learning models.

The data obtained was analyzed by making a description of the study results and the description of the data which consisted of the early stage descriptions and the end stage descriptions. The early stages descriptions consisted of normality and homogeneity tests. Normality test was performed by using the Kolmogorov-Smirnov test with a significance level $\alpha = 0.0$. The homogeneity test was performed by using the Leven's with $\alpha = 0.05$. The end stage description was hypothesis test. The effectiveness of the learning model test was performed by using one sample t-test, and the comparison between two models test was performed using independent sample t test. The difference average test between two classes had been done to determine whether there are differences of average between them or not. This test has been done using independent sample t test before the comparison test.

The learning model would be effective in terms of problem solving if the value of the post-test students more than or equal to the limit of KKM which was 76. Effective learning model in terms of the student's self-confidence was when the final score of the student's self-confidence was more than 70. It was based on the criteria of student's self-confidence as in Table 2.

TABLE2. CRITERIA OF STUDENTS' SELF CONFIDENCE

Score interval	Category	Criteria
$X > \overline{X_i} + 1{,}8Sbi$	X > 85	Very Good
$\overline{X_i} + 0{,}6Sbi < X \le \overline{X_i} + 1{,}8Sbi$	70< X ≤ 85	Good
$\overline{X_i} - 0{,}6Sbi < X \le \overline{X_i} + 0{,}6Sbi$	55 < X≤ 70	Pretty Good
$\overline{X_i} - 1{,}8Sbi < X \le \overline{X_i} - 0{,}6Sbi$	40 < X ≤ 55	Less Well
$X < \overline{X_i} - 1{,}8Sbi$	X ≤ 40	Not Good

$\overline{X_i}$: Ideal Mean = $\frac{1}{2}$ (maximum ideal score + minimum ideal score)

Sbi : Ideal standard deviation = $\frac{1}{6}$ (maximum ideal score – minimum ideal score)

X : Total score

III. RESULT AND DISCUSSION

A. RESULT

1) Data of Problem Solving Ability Score

Pretest and posttests' mean score of the first experiment class were greater than the second class. However, posttests' standard deviation of the second experiment class was lower than the first one, but the pretests' standard deviation was greater than the first class. The complete data of problem solving ability score are shown in Table 3.

TABLE3. DATA OF PROBLEM SOLVING ABILITY SCORE

Description	Firs Class		Second Class	
	Pretest	***Posttest***	***Pretest***	***Posttest***
Mean	48.56	83.38	45.24	80.91
Maximum	69	93	65	93
Minimum	31	68	19	68
SD	9.066	5.146	9.692	4.895
Variance	82.193	26.486	93.939	23.96

2) Data of Self-Confidence's Score

The first and the second class experiment not only got pre-test and post-test but also got scale of self-confidence before and after they were treated. The result had been analyzed. The difference between before and after self-confidence's scale can be seen in table 4.

TABLE4. DATA OF SELF-CONFIDENCE

Description	Firs Class		Second Class	
	Before	**After**	**Before**	**After**
Mean	71.06	72.44	70.70	72.24
SD	5.898	4.850	6.502	5.995
Variance	34.784	23.527	42.280	35.939
Maximum	81	83	80	84
Minimum	60	61	51	62

Based on table 4, it was found that before treatments' Mean score of both classes was relative same. However, before treatments' standard deviation score of first class experiment was lower than the second one. After treatments' Mean score of both classes was also relative same and before treatments' standard deviation score of first class was also lower than the second class experiment.

3) Data of Problem Solving Ability

Solving problem in this study was conducted through four steps, they were understanding problem, planning to solve, problem solving, and rechecking the answer. The results of pre-test and post-test which was used to measure students' problem solving abilities were analyzed based on each steps as shown in table 5.

TABLE5. DATA OF PROBLEM SOLVING ABILITY

		Understanding	Planning	Problem solving	Recheck
E_1	*Pretest*	9.18	6.53	6.53	3.97
	Posttest	13.03	11.53	10.32	11.79
E_2	*Pretest*	9.24	6.21	5.21	3.76
	Posttest	12.09	11.18	10.48	11.58

Based on table 5, it was found that the ability of students from each step in solving the problem on the first experiment and the second experiment class has increased. The significant increase was seen in rechecking.

B. DISCUSSION

1) Description of Implementation

The learning process both classes were conducted using lesson plan which was created and appropriated to the learning model for each class. Overall, learning process in the both of experiment class were appropriate with lesson plan (RPP) which was created.

In TPS with scientific approach class, students do process think, pair, and share. During the think process, students do activities to observe, ask, and collect information that is facilitated using Student Activity Sheet (LKS). They individually think about their answer of the problem which is presented in LKS. After that, they were formed in heterogeneous pairs. The formation of this pair is based on students' achievement scores before the experiments. During the pairing process, students are discussing about the problems that they had tried to break beforehand. The teacher calls on individuals or pairs to share with the large group in front of the class. Based on the observation, it is known that TPS with scientific approach learning was 97 % conducted.

In SGD with scientific learning process, students are directly conditioned for flocking spontaneously and variously on each meeting. They discuss about the problem that is presented in the Student Activity Sheet (LKS). After the students had a discussion, the teacher calls one by one group to present the results of their discussion. Based on the observation, it is known that SGD with scientific approach learning was 96 % conducted.

2) Description of Data

a. Normality and Homogeneity Test

Pre-test, post-test and students' self-confidence after and before treatment on both the experimental class were normally distributed due to the p-value (sig) > $\alpha = 0.05$. Homogeneity test results of the pre-test, post-test and students' self-confidence after and before treatment of the both experiment class are homogeneous. It was because the significant > $\alpha = 0.05$.

b. TPS Learning Model Combined with Scientific Approach is Effective in Terms of Problem Solving

In the first experiment class, the treatment given was learning math using TPS with a scientific approach. The effectiveness of learning mathematics using TPS with a scientific approach in terms of mathematical problem solving abilities are based on a minimum predetermined completeness criteria, that is 76. Learning is said to be effective if the average value of problem-solving abilities posttest of first experimental class is equal to or more than 76. Based on analyze using one sample t-test, the significant value is 0.000. This value is less than 0.05. It means that H_0 was rejected. In brief, Think Pair Share (TPS) learning model combined with scientific approach was effective in terms of problem solving abilities. Think Pair Share (TPS) learning model combined with scientific approach helped the students to solve the problem individually before they discuss in pairs and present the discussion result. Thinking individually led the students to solve the problem with knowledge which they have learned before. During the thinking process, students do activities to observe, ask, and collect information. These three scientific processes help student to improve their ability in understanding and planning the solution from the problem. Scientific approach leads the students to solve problem using steps in scientific approach. During the pair process, student share their answer. They discuss about the best solution for the problem. This condition improves students' problem solving ability. The effectiveness of TPS learning was supported by Eny Sulistianingsih [3] in her research that TPS learning model is effective in term of problem solving ability.

c. TPS Learning Model Combined with Scientific Approach is Effective in Terms of Self-Confidence

The implementation of TPS with scientific approach was not only seen from the problem-solving ability but also self-confidence of students. The effectiveness of this learning model is based on the value of the category of confidence that is more than 70. Based on analyze using one sample t-test, the significant value is 0.006. This value is less than 0.05. It means that H_0 was rejected. In brief, Think Pair Share (TPS) learning model combined with scientific approach was effective in terms of self-confidence. TPS learning model combined with scientific approach leads students to solve the problem confidently. They solve the problem individually and then discuss it with their pair. TPS learning model also facilitates students to share their discussion result in front of the class. This process improves student's self-confidence. According to Robertson [6], TPS cooperative learning model had many advantages which benefit students. The advantages of questions are increasing belief in the ability of the student. As it has been explained earlier that the belief in the ability of selfis one aspect of students' self-confidence, therefore, the more increase of belief in the ability of student the more increase of students' self-confidence. The results of this study was also supported by Fadiah Khairina Earth [4], which states that TPS combined with problem-based learning will increase the confidence of students.

d. SGD Learning Model Combined with Scientific Approach is Effective in Terms of Problem Solving

In the second experiment class, the treatment given was learning math using SGD with a scientific approach. The effectiveness of learning mathematics using TPS with a scientific approach in terms of mathematical problem solving abilities are based on a minimum predetermined completeness criteria, that is 76. Learning is said to be effective if the average value of problem-solving abilities posttest of first experimental class was equal to or more than 76. Based on analyze using one sample t-test, the significant value is 0.000. This value was less than 0.05. It means that H_o was rejected. In brief, Spontaneous Group Discussion (SGD) learning model combined with scientific approach was effective in terms of problem solving abilities. SGD learning model combined with scientific approach manages students to discuss the problem in group. Each group consisted four or five members. Students followed the instructions in scientific approach to solve the problem. This situation is beneficial for students to practice solving problems by way of discussion. This is in line with the opinion of Tukiran Taniredja, et al. [20], that the benefits of the discussion group is train students to identify, solve problems and make decisions together. The results of this study was also supported by Ratih Damayanti [15], who states that SGD learning models increase students' activity of solving problem from 17.4 % to 73.91 %.

e. SGD Learning Model Combined with Scientific Approach is Effective in Terms of Self-Confidence

The implementation of SGD with scientific approach was not only seen from the problem-solving ability but also self-confidence of students. The effectiveness of this learning model is based on the value of the category of confidence that is more than 70. Based on analyze using one sample t-test, the significant value is 0.039. This value is less than 0.05. It means that H_0 was rejected. In brief, Spontaneous Group Discussion (SGD) learning model combined with scientific approach was effective in terms of self-confidence. SGD learning model combined with scientific approach facilitate students to share their idea in group. This process demands each student to take a responsibility to their groups' members. According to Lauster [19] responsibility is one of the aspects of self-confidence. Its means, if students' responsibility was improved, the self-confidence will increase. SGD learning model combined with scientific approach also facilitate students to share their result of the discussion in front of the class. This process will also improve students' self-confidence.

f. Result of Difference Average Test

Difference average test had been done to variables after and before treatment. The result of the test is shown in Table 6.

TABLE6. RESULT OF DIFFERENCE AVERAGE TEST BEFORE TREATMENT

Variable	**Data**	**Mean**	**Sig.**

Variable	Data	Mean	Sig.
Problem Solving	E_1	48.56	0.153
	E_2	45.24	
Self-Confidence	E_1	71.06	0.812
	E2	70.70	

Based on Table 6, it is known that the pre-test and the scale before treatment had significance value more than 0.05 so H_o was accepted. It means there was no difference average between first experiments class and second experiments class in term problem solving ability and self-confidence.

After that, the result of difference average test after treatment is shown in table 7.

TABLE7. RESULT OF DIFFERENCE AVERAGE TEST AFTER TREATMENT

Variable	Data	Mean	Sig.
Problem solving	E_1	83.38	0.048
	E_2	80.91	
Self-Confidence	E_1	72.44	0.882
	E_2	72.44	

Based on table 7, it is known that the post-test of problem solving had significance value 0.048. This value is less than 0.05 so that H_o was rejected. It means that the average between the both of class experiment in terms of problem solving ability was different. In other word, one of the two learning model is more effective than the other.

The result of self-confidences' scale after treatment, had significance value is 0.882. This value is more than 0.05 so H_o was accepted. It means that there was no difference between the first and the second experiment class in terms of students' self-confidence. In other word, TPS learning model combined with scientific approach is as effective as SGD learning model combined with scientific approach in term of self-confidence.

g. TPS Learning Model Combined with Scientific Approach is More Effective than SGD Learning Model Combined with Scientific Approach in Terms of Problem Solving

Based on analyze using independent sample t-test, the significant value is 0.048. This value is less than 0.05. It means that H_o was rejected. In other words TPS learning model combined with scientific approach is more effective than SGD learning model combined with scientific approach in term of problem solving ability.

TPS learning model combined with scientific approach helped students to solve the problem individually before they discuss in pairs, but in SGD learning model combined with scientific approach, students directly discuss the problem in group. It is the reason why students get better study's chance in TPS model. Members of group in TPS learning model combined with scientific approach were less than members of SGD learning model combined with scientific approach. That's why discussion in TPS learning model is more effective than discussion in SGD learning model. This study was in line with the opinion of TukiranTanureja [20] that the formation of the group will be effective if the number of members is not too much, so there will be no member who just boarded the name.

h. TPS Learning Model Combined with Scientific Approach is as Effective as SGD Learning Model Combined with Scientific Approach in Terms of Self-Confidence

Based on analyze using independent sample t-test, the significant value is 0.882. This value is greater than 0.05. It means that H_o was accepted. In other words TPS learning model combined with scientific approach is as effective as SGD learning model combined with scientific approach in term of self-confidence. TPS learning model combined with scientific approach leads student to solve the problem confidently. They solve the problem individually and then discuss it with their pair. SGD learning model combined with scientific approach leads student to solve the problem confidently with different members of the group in every different meeting. Both of learning model has sharing process that facilitates students to share their discussion result. This process will improve students' self-confidence.

IV. CONCLUSIONS AND RECOMENDATIONS

A. CONCLUSIONS

Based on the result, the researchers concluded:

1. Think Pair Share (TPS) learning model combined with scientific approach is effective in terms of problem solving.
2. Think Pair Share (TPS) learning model combined with scientific approach is effective in terms of self-confidence.
3. Spontaneous Group Discussion (SGD) learning model combined with scientific approach is effective in terms of problem solving.
4. Spontaneous Group Discussion (SGD) learning model combined with scientific approach is effective in terms of self-confidence.
5. Think Pair Share (TPS) learning model combined with scientific approach is more effective than Spontaneous Group Discussion (SGD) learning model combined with scientific approach in terms of problem solving.
6. Think Pair Share (TPS) learning model combined with scientific approach is as effective as Spontaneous Group Discussion (SGD) learning model combined with scientific approach in terms of self-confidence.

B. RECOMMENDATION

Based on the results of the study, it is recommended to use TPS learning model combined with scientific approach and SGD learning model combined with scientific approach to improve students' problem solving ability and self-confidence. However, to get better result in improving students' problem solving ability, using TPS model combined with scientific approach is more recommended.

***Abstract*—** The purpose of this study is to investigate the characteristics of teachers' scaffolding in teaching and learning mathematics carried out by two teachers showing contingent dominant interaction. The characteristics were obtained by examining the conversations fragments between teachers and students during the provision of scaffolding. The fragments of conversation which were recorded by a video recorder were then transcribed for data analysis. The result shows that although the two teachers had the same contingent dominant interaction, they expressed different approach to contingencies characteristics in their scaffolding activities consisting of analytic and intuitive. In addition, the teacher using analitic contingent dominant interaction is likely to provide scaffolding more strictly and deeply in providing learning assistance to students compared to that of the teacher using intuitive contingent dominant interaction.

Keywords: *analytic, characteristics, contingent dominant, intuitive, scaffolding*

I. INTRODUCTION

Scaffolding has been in great demand in the field of mathematics education of recent studies [1], [2], [3]. The study of scaffolding strategies in geometry found that the involving student participation is the scaffolding strategy that frequently used by teachers [1]. The study of scaffolding used by two mathematics teachers with different teaching experiences found that scaffolding conversations appeared to have a positive impact on the learning and scaffolding using manipulative tool frequently appeared to have a positive feelings about using materials [2]. Furthermore, [3] tried to apply the idea [4] which introduced the scaffolding in mathematics as a "tool-for-result" and as a "tool-and-result" to distinguish the two dialogues of teachers-students in elementary school. However, all those studies have not yet examined in detail regarding the provision of scaffolding by teachers during dialogue. Therefore, the contingency of scaffolding as a match between what the teachers and students understood as a dialogue [5], should be studied further in the integrated concept in teaching and learnin [6].

Scaffolding is one of the characteristics of effective teacher-initiated teacher-student dialogue on the learning of mathematics. It deals with the ways in which teachers use dialogue to scaffold students' understanding. According to [7], few of the studies provide evidence that such characteristics actually led to promotion of students' conceptual understanding of mathematics. Actually, dialogues between teachers and students when scaffolding can eveal the extent to which teachers approach to students' understanding. So, through dialogues, the teachers' characteristics associated with scaffolding given can be known.

Patterns of the contingent teaching when scaffolding in social science, i.e. contingent and non-contingent have been introduced in [5]. However, the characteristic of mathematical content that is abstract and requires deductive thinking implies different approach to facilitating student learning than approach to learning social sciences. Refer to [5], the study on contingency patterns of interaction in the context of mathematics teaching and learning when teachers provide scaffolding to students showed three patterns of interactions, namely: the contingent dominant, the non-contingent dominant, and the pseudo-contingent [8]. Of course, effective teachers would want to have a contingent dominant interaction in the teaching and learning. So, the study of the characteristics of teachers' contingent dominant interaction when scaffolding is more interesting than the study of characteristics of teachers' non-contingent dominant or pseudo-contingent interaction. However, the study about it has not been revealed by researchers yet. Therefore, the research is needed to investigate the characteristics of teachers' caffolding in learning and teaching mathematics carried out by teachers showing contingent dominant interaction. The results of this study are indispensable for future research in uncovering the thinking processes of the contingent dominant teachers when scaffolding in teaching and learning mathematics.

II. THEORETICAL FRAMEWORK

A. *Effective Mathematics Teacher*

Effective teachers will be able to understand and apply various strategies to help the students improve the learning outcomes [9]. Generally, mathematics teachers help students by means of dialogue either as individuals or groups related problem or a math assignment. The dialogue can be initiated by the student or the teacher. Dialogue can occur when a student asked about mathematical objects which are being facilitated by teachers (concepts, principles, or procedures) that have not understood by students yet. Dialogue can also occur because teacher read the conditions of the students psychologically who are deadlocked in their duties. However, based on observations of the researchers, the dialogue often occurs when teachers allow students asking while doing exercises. Assistance provided by the teacher when this dialogue is meant as scaffolding in this study.

Why dialogue? According to [6], the dialogue is one key to the success of scaffolding. Through dialogue, there will be a balance of what was presented by teachers with the students' understanding. Added by [3] that knowing mathematics is helping students through dialoging and doing. Therefore, scaffolding and dialogue in learning mathematics are closely linked to one another. Both of these have the same origin sourced from psychology education as proposed by [10]. Therefore, an effective mathematics teaching and learning must necessarily dialogue.

B. Scaffolding in Learning Mathematics

Scaffolding is part of the learning strategies that require the teacher's role to facilitate student learning [11]. Through scaffolding, students are expected to have independence in learning the material that is facilitated by teachers [12]. At the end of the scaffolding, the teacher's responsibility has been left entirely to the students so that students are able to perform their duties independently [5].

Practically, the provision of scaffolding on math learning can be different from one teacher to another According to [13], there are teachers who are able to provide scaffolding in a certain way, but the teacher was unable to give any other way. For teachers who have the knowledge, skills and experience to facilitate lesson well, then they will be able to guide students towards in deep understanding. Of course, it differs from teachers who have less knowledge, then he will have a hard time helping the students. Therefore, the provision of scaffolding is very dependent on the knowledge, skills, and experience of teachers in providing scaffolding [14].

C. The Contingency of Scaffolding in Teaching and Learning Mathematics

Contingency is a requirement for scaffolding [5]. If a teacher gives the scaffolding to students contingently then the scaffolding should be gradually reduced so that the teacher's responsibility should really have been transferred to the students. Assistance given by the teacher to the student should be appropriate to the level of students’ understanding. In other words, when scaffolding, teacher need to show the interaction that adjusts assistance given to the condition of the students.

Knowing the contingency of teachers’ scaffolding means that analysing of the fit between teachers’ help and the students' understanding. It can be done by teacher using D (Diagnostic strategies), I (Intervention strategies), and C (Checking of diagnosis). In analysing the diagnostic strategies, teachers focus on: (a) the posing of diagnostic questions and (b) the reading of student work, to discover the level of the student’s ability to perform without assistance. Checking of the diagnosis means verifying whether teachers have understood the students correctly or not. Checking of diagnosis will give teachers more information on understanding and students' strengths. In the intervention strategy is simply defined as a strategy used to support the student by giving the feedback, hints, instructing, explaining, modelling, and questioning (assisting) [5]. Refer to [5], the interaction learning math teachers are naturally contingent dominant still hard going [8]. Observations [8] to the math teachers in Malang, only 10% of teachers demonstrated contingent diminant learning interactions. These conditions would have to continue to be sharpened as consideration for teachers or decision-makers to improve the process of teachers’ scaffolding in the classroom. Therefore, efforts to investigate the characteristics of teachers’ contingent dominant scaffolding needs to be done to enrich the science, especially how teachers provide scaffolding to students contingently.

III. METHOD

Researchers surveyed 25 mathematics teachers in Malang since 2015 and found two contingent dominant mathematics teachers in scaffolding, i.e. AD, and DW. AD (male mathematics teacher) had a master degree and four years of teaching experience in Senior High School. DW (female mathematics teacher) had a bachelor degree and four years of teaching experience in Madrasah Aliyah. Both teachers taught trigonometry subjects for the 10^{th} grade.

The research data in the form of a dialogue transcription teachers and students when scaffolding obtained from video of learning. The fragments of conversation which were recorded by a video recorder were then transcribed for data analysis. Analysis of data using qualitative method. For the purposes of data analysis, researchers encode any statements or questions in the dialogue with the code fragment aforementioned, i.e. D, C, or I, refers to Appendix F in [15]. At the same time, researchers play the video to see teachers' scaffolding according to the context of the problem. Because of many fragments, researchers only focused on analyzing the most representative fragments corresponding context of the problem and occurs naturally in the material scope of trigonometry.

IV. RESULTS

General information about the learning interaction fragments by two contingent dominant mathematics teachers in this research is presented in Table 1.

TABEL 1. GENERAL INFORMATION ABOUT TEACHERS' CONTINGENT DOMINANT SCAFFOLDING IN TEACHING AND LEARNING MATHEMATICS

Teacher	Problems	Scaffolding Contingency Strategies Used by Teachers			Characteristics of Teachers' Scaffolding
		Number of Diagnostic Strategy (D)	*Number of Intervention Strategy (I)*	*Number of Checking of Diagnosis Strategy (C)*	
DW	Determine sine 270^0	4(18,18%)	13(59,09%)	5(22,73%)	- Performing diagnostics strategy by questioning - Implementing intervention strategy dominantly - Doing checking of analysis strategy in less rigorous and less deep - Encouraging students toward procedural understanding - Often implementing the strategies by requesting "go on", less asked for justification, and failed to give feedback on the students' answers - Emphasizing the dialogue to encourage students to focus on getting the answers than thinking processes - Using "tool-for-result" approach dominantly - The conclusion: Teacher uses an intuitive approach
AD	Determine sin $(90\text{-}\theta)^0$, known sin $\theta = a$, $a \neq 0^0$.	8(24,24%)	9(27,27%)	16(48,48%)	- Performing diagnostics strategy by reading the student's work and questioning - Implementing checking of analysis strategy dominantly - Conducting checking of analysis stricly and deeply - Encouraging students toward a conceptual understanding - Often implementing the strategy by using the question "why", asking for justification, and providing feedback by commenting on the students' answers - Emphasizing the dialogue that encourages students to get answers thoughtfully - Using "tool-and-result" approach dominantly - The conclusion: Teacher uses an analytic approach

A. DW's Description of Teaching Interaction

The following fragment is DW dialogue with students in developing contingency learning interactions when doing trigonometry exercises, i.e. when students asked for the value of sine 270^0.

Fragment 1

Line 1: S: Here Mis ...do I take 90^0 or zero? If I mean that in 270^0 ...looking for sine 270^0... is it minus 1 ... or should I remain the same as that of what I take, that is sine 90^0, so you know ...?
Line 2: T: What do you mean with how to take the 90^0? [D]
Line 3: S: I mean that will I take sine 90^0, so you know Mis?
Line 4: T: yes ...
Line 5: S: Why don't we take 0^0 Mis ... but ...
Line 6: T: You make sure ...that 270^0 that you want...what quadrant will you take! [I, Instructing]

Line 7: S: It is the third or the fourth, Mis ...
Line 8: T:The third or the fourth ... certainly you make sure ....whether to take the third or the fourth quadrant? [I, Questioning]
Line 9: S: Yes it is ...Mis ... [the student is getting confused with a slight laugh]
Line 10: T: Don't be confused ... chose it! ... [I, Instructing]
Line 11: S: Oh ...
Line 12: T: Choose one! ... [I, Instructing]
Line 13: S: [pause] ... if in the third quadrant...it becomes 90^0...[student thinks aloud]
Line 14: T: e e ...
Line 15: S: If I take the fourth quadrant...it becomes 0^0... [student thinks aloud]
Line 16: T: e e ... ok come frward, which one... is it right? [D]
Line 17: S: Yes
Line 18: T: Now choose one ... so ... let's say .. if the third quadrant is chosen .. do we use the angle? [I, Feedback, Hints]
Line 19: S: 90^0 ...
Line 20: T: yes already ... we use the angle of 90^0 ...do not use the zero one .. [I, instructing]
Line 21: S: [students paused]
Line 22: T: If we take the zero ... do we..use 270^0 minus zero, if so, is it you mean? [D]
Line 23: S: Not ..I mean ... right ... like this anyway Mis ... [students tried to explain the meaning of the question with drawing] It's 270^0 ...
Line 24: T: em
Line 25: S: if we are right with this way ... 90^0 ...
Line 26: T: em em
Line 27: S: Mis, from this 90^0 ... but if we follow the portrait...we have 0^0...here.
Line 28: T: Please try to count it... calculate it ..compare it ... let's see...what quadrant do we take?... [I, Questioning]
Line 29: S: The third
Line 30: T: The third quadrant... try ... how? [C, Instructing]
Line 31: S: This is sine...it means ...minus 1, right? [student explains about the third quadrant]
Line 32: T: em ..
Line 33: S: If here is cosine [student shows four quadrants,] meant that ... zero
Line 34: T: Cosine ... how would it be cosine?. [C]
Line 35: S: Sine is zero
Line 36: T: How does sine become zero? [D]
Line 37: S: Zero
Line 38: T: zero ..please go on...try to write it ...yes write it... I'm confused too ... write in two ways ... how does the first way...and how does the second way...which way to have the correct answer? ... [I, Hints]
Line 39: S: [students write the answers on a blank paper, sin 270^0= -sin 90^0)]
Line 40: T: [Teachers pay attention to the students' work] Please write how you found $90^{0...}$The way can be displayed... please! [C, Questioning (assisting)]
Line 41: S: [students delete what she wrote and write the new answer]
Line 42: T: em em ... [teachers pay attention to the students' work] Try the second way ... [C, Questioning (assisting)]
Line 43: S: [students write the second way] oh yes yes Mis ... [Students stop his work because they feel satisfied to the answer]
Line 44: T: Try to continue ... to convince the answer .. [I]
Line 45: S: [students continue completing the work]
Line 46: T: [Teachers pay attention to the work of students] sine is minus 90 ... keep anyway? No such effect ...
Line 47: S: Yes yes yes
Line 48: T: If you want to exclude from the limit ... earlier or later ... no problem ... but you should be consistent ... seen from the characteristics..what is potitive...what is...[I, Instructing]
Line 49: S: Negative
Line 50: T: It is the same, isn't it? [C]
Line 51: S: Yes yes yes ...
Line 52: T: Well, this is minus sine 90^0[Teacher reminded to use minus sign (-) before sine 90^0] Is it the same? Take one only ... [The teacher left the student] [I, Hints]

Based on the fragment above, DW applies diagnostic strategies (lines 2, 16, 22, 36), intervention strategies (lines 6,8, 10, 12, 18, 20, 28, 35, 37, 39, 44, 48, and 52), and checking strategy analysis (lines 30, 34, 40, 42, and 50) when the scaffolding. However, DW uses the intervention strategy dominantly. DW is more focused on how to find the results. DW uses intuitive approach to the provision of scaffolding. In view of this, a mathematical intuition is not associated with formal reasoning. Namely, DW presents a mathematical problem in how to find the answers immediately, without need to have justification or formal analysis. The researchers mentioned DW as classical intuitionist [16]. Even if there is to discover students' knowledge as a support, such as the question; "Why?", "How do you know that?", are still rare. DW often does the interactions like that. This conformed to the findings [17] that teachers rarely explored right naturalness of students problem.

DW rarely conduct an investigation into what is being done by students. In other words, the assistance provided by DW less deep to explore the knowledge of students. DW often use intervention strategies by giving hints (clues) or feedback. In fact, DW reminded students to make the conclusion that is being done. The contingent dominant approach of the provision of scaffolding that impressed DW done quickly, not long, less to enable children to think deeply, and spontaneously. DW tends to encourage students toward procedural understanding. DW rarely ask the question "why", asked for justification, and comment on the students' answers. DW emphasizes dialogue to encourage students for finding the answers rather than thinking. Therefore, considering the characteristics scaffolding done by DW, the researchers mention that DW as a teacher who has intuitive contingent dominant characteristis.

B. AD's Description of Teaching Interaction

Here is a fragment of scaffolding when AD taught trigonometry in determining sin (90 - θ), known sin θ = a, a $\neq$ 0.

Fragment 2

Line 1: S: How about the second number, Sir?
Line 2: T: Second number ...have you completed it? [D]
Line 3: S: Not yet
Row 4: T: [The teacher read the student's work while pointing out] If this.. is simplified, so what will happen?[D, C, Questioning]
Line 5: S: What?
Line 6: T: It's, you know ... [Teacher sees the student writing sin (90-q)] [I, Hints]
Row 7: S: Ninety ... [Student thinks hard]
Row 8: T: Sine of ninety degrees min theta... if is simplified... [the teacher pointed to the 90-θ] [C, Feedback]
Line 9: S: Sine theta...
Line 10: T: Well ... It's ... 90^0, right? [Pointing to article 90^0-θ] [D]
Line 11: S: Yes
Line 12: T: What's kind of axis...this? [D]
Line 13: S: The Y-axis
Line 14: T: If there is a reference axis of Y ... Y ... [C, Questioning]
Line 15: S: Reversed to cosine Y
Line 16: T: Yes ... the result is ... [C, Questioning]
Line 17: S: Cos θ
Line 18: T: Yes already [Feedback]
Line 19: S: [keep silent]
Line 20: T: What is known? [D]
Line 21: S: Sine θ
Line 22: T: What will you find? [D]
Line 23: S: Cosine θ
Line 24: T: How can it be? [C, Questioning]
Line 25: S: Reversed, right?
Line 26: T: Lho...why is it reversed?... sinus is known ... keep looking cosine θ .. θ, How do you find it? [C, Feedback]
Line 27: S: [pause, confused]
Line 28: T: [Teacher directly asked the question] if sine θ is known... what is the comparison of sine? [C, Feedback, Questioning]
Line 29: S: opposite ...hypotenuse ... oh ..looking ...adjacent...
Line 30: T: Lho .... it means that what should be drawn?. [I, Questioning]
Line 31: S: Drawing a triangle
Line 32: T: What triangle? [D]
Line 33: S: Right triangle
Line 34: T: Yes ... draw it, try! [I, Instruction]
Line 35: S: Sinus ..opposite ...hypotenuse ...
Line 36: T: Set the first angle ... [The teacher immediately cut the student's statement] [I, Hints]
Line 37: S: [students draw a triangle while thinking aloud]
Line 38: T: No ... only its angle ... [I]
Line 38a: S: [Doing]
Line 39: T: Yes ...
Line 40: S: ..opposite ..hypotenuse...a, sir?
Line 41: T: a ... the "a" is meant...? [C, Questioning]
Line 41: S: [students is thinking] em?
Line 42: T: a.. means ... the same as ? [C, Questioning]
Line 43: S: 1
Line 44: T: Yes ... the same as opposite over ... [C]
Line 45: S: Hypotenuse...
Line 46: T: Yes..how is that?. [I, Questioning]
Line 47: S: 1
Line 48: T: Why is 1? [C, Questioning]
Line 49: S: a is divided by one ... a
Line 50: T: yes .... It means… is it the line? [The teacher showed a right angle of triangle] [C]

Line 51: S: 1... a
Line 52: T: Lho, why? .. [Teacher asked for the reasons of getting 1 surprisingly] [C]
Line 53: S: Oh ... 1 minus a ...
Line 54: T: Lho... why 1 minus a? [Teacher asked for the reasons of saying 1 minus a surprisingly][C]
Line 55: S: 1 min ... a square ...
Line 56: T: go on ... [teachers justify] [I]
Line 57: S: It is rooted ...
Line 58: T: Okay, rooted ...then... [Feedback]
Line 59: S: How is this? [Student try to root ...while thinking aloud] one minus ....
Line 60: T: It cannot, ... can you? [D]
Line 61: S; 1 min a squared ...Sir?
Line 62: T: Lho ... it's worth ... it is still ... [C]
Line 63: S: But ... that's not the point ... like this, you know ... [students write the sgns of under root of 1- a squared]
Line 64: T: Yes ... keep being asked about? [D]
Line 65: S: Cosine
Line 67: T: Write, please! [I, Instructining]]
Line 68: S: Cos b
Line 69: T: Lho ... cosine theta [justifying the way the students read Cos b of which it should be theta] [I]
Line 70: S: opposite...hypotenuse [students write] 1 per root ....
Line 71: T: Lho, cosine theta you know ... [I]
Line 72: S: Oh ya ..ya ..it was reversed ...reverssed ... [students failed to determine the ratio of 1 to the root of $(1 – a^2)$*]... yes ...this is the answer! [while he saw no option not to answer the question] Oh, ... oh yes yes... [student reveals satisfaction in her work]*
Line 73: T: [Teacher left the student]

Based on the Fragment 2, AD starts providing the scaffolding using diagnostic strategy (D) by questioning using wh-question or yes/no question (line 2, 4), reading the students work, and continuing to use checking strategy directly (line 4). In general, AD implementing three strategies scaffolding almost evenly, although slightly more dominant implementing checking strategy (lines 4, 8, 14, 16, 23, 25, 27, 29, 40, 42, 44, 48, 50, 52, 54, and 62). It was demonstrated that AD provides scaffolding to students strictly, which began with an intervention in the form of a question that asks every step of the student after performing diagnostics. Almost every step of workmanship students are faced with the question "why or *lho*", as a way to reinforce the problem or checking (*Lho* is a special word that expressed surprise or shocked in the Javanesse). AD is more dominant inquire initial concepts and skills (procedures) of that students did and students will do. AD does not let students write just the answer without questioning as student to teacher accountability. In other words, AD strictly controlling every step in the order execution strategies help students apply D (Lines 2, 16, 19, 21, 31, 36, 60, 64), I, C or D, C, and I strategies.

AD is very often generate the interactions such as Fragment 2. As a whole interaction, AD almost equal implements the three strategies (D, C and I) in providing scaffolding (can be seen in Table 1). Although the strategy of checking of doagnosis (C) is more dominant than the other two strategies, but AD’s intervention strategies do not directive in the sense of giving out the answers but rather intervence students to think about issues being worked student. AD tends to do well in solving the problem. AD tried to breakdown the problem into small parts of pieces of students work. A small section was more probing students' prior knowledge about the fact that demands memorizing. This is in accordance with the said [18] that the analytic resolve the problem based on facts and logic rather than emotion. Based on this description, the researchers mention that AD as a teacher who has analytic contingent dominant characteristic.

V. DISCUSSION

Learning is a process of building relationships between teachers and students in mathematics in order to construct meaning both individually and collectively [19]. This research has shown the empirical facts about the characteristics of teachers’ contingent dominant scaffolding in teaching and learning mathematics in order to construct mathematical meaning, specially in trigonometry. Although this study did not generalize the findings, but the empirical evidence has shown that the contingency provision of scaffolding can be reached by teachers through two approaches, i.e. intuitive and analytic. Empirical evidence also showed that the interaction of contingent dominant learning mathematics teacher are possible on the background of different types of schools, i.e. a public high school and religious schools. However, the ability of teachers about the material presented is a factors to consider and have not been studied in this research.

As shown in Fragment 2, AD used a strategy that breakdown the student understanding when scaffolding. When students asked about the concept or procedure that is not understood, AD does not only help students to resolve the question asked but AD also expands these problems by exploring related concepts of the problem. In other words, AD tends to implement the checking and intervention strategy through questioning with the aim of "assisting". Each student responses when scaffolding followed by excavation deeply about what is known, and what is understood, by students. Furthermore, AD uses information from the student's response to resolve the problem presented students. In the dialogue, AD does not believe the student's response before the students were able to answer every question asked by AD in connection with concepts or facts. It could be argued that the scaffolding by AD is conceptual. It was conscious and was impressed slow. Considering such a process, the authors state that AD uses an analytic approach in his scaffolding.

Contrary to AD, as shown in Fragment 1, DW dominantly use intervention strategy with focus on results being achieved, not focus on the process. When students asked about the concept or procedure that they have not understood yet, DW focuses on helping student to the question without extending the problem in the question or without digging the concepts involved deeply. In other words, scaffolding of DW tends to be procedural. This happens spontaneously and quickly. Considering such the process when scaffolding, the authors states that DW uses an intuitive approach.

Actually, the two teachers in this study have shown a good approach in the provision of scaffolding because both have shown the contingent interaction. However, the opportunity to engage students in learning mathematics need attention by the teacher. Moreover, learning is not about receiving information but more than that, learning is about building relationships to construct a strict mathematical meaning [19]. Therefore, what is done by the AD above is actually very consistent with the concept of learning desired in the classroom. As stated by [19] that the class should be a place where teachers and students engage in learning activities that are rigorous mathematics. Opportunity should exist in a class that allows the teacher relates to students. Added by [19] that as many teachers ask questions to the students and the question was not just recall, it gives students the opportunity to express their ideas and verbal activity can develop students' understanding.

When associated with a dual theory of S1 and S2 according to [20], both teachers demonstrated in different ways. AD using S2, as though the help seems slowly, but he was full of awareness in helping children to understand, not only results. According to the view [4], AD approach known as "scaffolding as tool and result". This differs from the DW help children tends to get results only. According to the view [4], DW approach known as "scaffolding as a tool for result". The differences of interaction of both teachers can be influenced by several factors, e.g. the teachers' experiences, type of school, and learning approach that transactions are carried out [14]. Both the teachers in the study are different educational backgrounds. AD is a master educational background, while DW is a scholar. Of course, the experience of this background needs to be considered in establishing contingency, especially the two teachers belong to a relatively young age and have a high motivation. However, the interesting in this study is that even teachers with less than five years experiences, both AD and DW are able to show learning the contingent dominant interaction patterns naturally.

All the three strategies built by the teachers in scaffolding need guiding, including language problems or questioning skills. As in [21] that if learning occurs in social interaction, language or speech is an important tool for communicating and guiding learning. Through language, a student can express his understanding, giving reasons, posing a problem, and learning. Through language, teachers and students are able to build shared knowledge in interaction, i.e. they are thinking. Therefore, teachers need to have the skills of questioning. According to [22], based on the level questioning can occur: 1) at a low level, asking the skills, and 2) a high level, that asks or encourages thinking like asking to explain the process of what is found.

Of course, this study has some limitations. First, this study only just looked at two new teachers' contingent dominant interactions when scaffolding. Second, the issues raised in this study only in trigonometry that is in similar problems. Therefore, future research can be conduct by lifting the same exact problem and more than two teachers (if possible). But it will not be easy to do because to find the contingent dominant teacher in mathematical scaffolding is a tiring job.

VI. CONCLUSION

This research found the characteristics of teachers' scaffolding in teaching and learning mathematics carried out by two teachers showing contingent dominant interaction, namely: intuitive and analytic. The teacher whose intuitive contingent dominant interaction tends to use the approach that explore the informal knowledge or the intuitive knowledge of students to develop procedural knowledge. This aproach can be reached by starting the process of scaffolding through an easy problem for students. From here, teachers can develop students' understanding. Via this approach, the teacher has a quickly and less digging the student understanding. Some characteristics of this approach of teachers are: faster, less strict, less careful, spontaneous, very considering limit of time, and using scaffolding as "tool-for-result".

Teachers whose analytic contingent dominant interaction is likely provide the scaffolding approach by exploring formal and procedural knowledge of students to develop conceptual knowledge. Teacher can reached this approach with the help of probing students understanding. From here, the teacher can develop students' understanding and a mindset of students to thrive in solving the next problem. Some of the inherent nature of this kind of teacher are: tight, rigor, meticulous, long, carefully, seriously, no matter of limit of the time of teaching, unpretentious, and using scaffolding as a "tool-and-result". So, teachers using analytic contingent dominant interaction is likely to provide scaffolding more strictly and deeply in providing learning assistance to students compared to that of the teacher using intuitive contingent dominant interaction.

Effectiveness Problem Based Learning And Scientific Approach To Improve Higher Order Thinking Skills

Arini Ulfah Hidayati[1], Heri Retnawati[2]
[1]Master Program of Mathematics Education, Yogyakarta State University
[2]Faculty of Mathematics and Natural Science, Yogyakarta State University
ariniulfah_hidayati@yahoo.com

Abstract— This article aims to describe theoretically the effectiveness of problem based learning and scientific approach to improve higher order thinking skills. Problem-based learning and scientific approach is the same approach - the same student-centered, students not only gain knowledge directly, but also students should build their own knowledge. Problem-based learning is an approach centered learning students the basic problem is presented in the form of real problems, charming, authentic, ill - structured and a variety of variations to finish with the advantages of developing the problem solving ability of students, develop higher order thinking and scientific skills, integrating theory and practice, and motivate them, develop time management and data collection. While scientific is an approach to learning students actively integrating students in the process of thinking and the use of methods that are scientifically proven by conducting experiments to test the hypothesis, with the advantages of encouraging and inspiring students to think critically, to inspire learners are able to think hypothetically see the different, similarities and link to one another on the substance of learning materials. Higher order thinking skills is a process of thinking skills in depth and widespread that involves information processing in critical and creative in facing and resolving problems that are complex include critical and creative thinking skills. Syntax of PBL used to increase HOTS include (1) supply issues, (2) strategic planning, (3) investigation, (4) presented the results and (5) evaluating, whereas syntax of scientific approach used include: (1) observing, (2) questioning, (3) associating, (4) reasoning and communicating.

Keywords: *problem-based learning approach, scientific approach, higher order thinking skills*

I. INTRODUCTION

The development of science and technology in the century - 21 is rapidly have led to competition in many areas of life , including education. Human resources will be generated from the high-grade quality education, to train students' thinking skills and produce high-quality output that will require higher thought processes, skill in question is a high-level thinking skills are often called Higher order thinking skills (HOTS). Higher order thinking skills is a process of thinking skills in depth and widespread that involve processing the information critically and creatively in facing and resolving problems that are complex include critical and creative thinking skills [1], [2], [3], [4], [5], [6], [7]. Therefore, the government did not remain silent to always make changes such as holding facilities and infrastructures then revise the current curriculum of the Education Unit Level Competence (SBC) was revised to Curriculum 2013. The curriculum is aimed at improving the quality of human resources and enhance the nation's competitiveness, and along with the development of science, technology and art. The curriculum is expected to produce human resources productive, creative, innovative and affective competencies through strengthening of attitudes, knowledge and skills [8]. But the fact that the government declared curriculum has not been fully realized with the expected, according to [9] there are four obstacles teachers in implementing the curriculum in 2013 one difficulty to enable students in the classroom.

In the learning process needed both models, strategies, and learning approaches that can optimize the learning activities of students in the training of high-level thinking skills. One of them problem-based learning (PBL) is a learning approach centered on the students the basic problem is presented in the form of real problems (real word), charming, authentic, unstructured (ill - structured) and a wide variety to complete [10], [11], [12]. PBL theoretically could increase higher order thinking skills [13], [14]. Learning problem based learning is conducted in stages presents a problem, strategic planning, investigation, presented the results and evaluate. In addition leraning problem based learning, curriculum 2013 also recommends the scientific approach. Approach scientific an approach to student learning actively integrating students in the process of thinking and the use of methods that are scientifically proven by conducting experiments to test the hypothesis, with the advantages of encouraging and inspiring students to think critically, to inspire learners are able to think hypothetically in seeing the differences, similarities and link to one another on the substance of the study [15], [16] [17], [18].

Scientific taught us to think why something is happening ?, and what causes something to happen? then what about the solution of the problem that has occurred? [15]. From here students are encouraged to think radically and critically. The scientific approach is conducted in stages: observe, ask, gather information, reason and communicate.

Based on two approaches that have been mentioned are problem-based learning and scientific approach theoretically they can increase students' higher order thinking skills are critical and creative, so it is important to compare the two, which is more effective when used in learning, especially learning math.

II. Discussion

A. Higher Order Thinking Skills

High-level thinking skills necessary to be applied to the students, because it will train students to think critically, creatively and skeptical of the problems encountered in the century - 21's. [19] states: "The definition of essential thinking skills: thinking is Generally assumed to be a cognitive process, a mental act by the which knowledge is acqured". This is in accordance with [20] on Graduates Competency Standards for Primary and Secondary Education stated qualifications in the ability of junior-dimensional skills have the ability to think and act of effective and creative in the realm of the abstract and the concrete in accordance with the learned in school and learning resources similar.

Thinking is a mental activity that a person experiences when faced with a problem or situation that must be resolved. [21] revealed some sense thinking: (1) thinking is a process that involves surgery - mental operations such as induction, deduction, clarification and reasoning, (2) thinking is a process of representation symbolically (through language) various objects and events real use it to find a symbolic representation of the principle - essential principle. (3) thinking is the ability to analyze, mengkkritik and make generalizations. Furthermore, [22] declared four levels of thinking (level of thinking) as follows; (1) Recall (Given) at this stage a person requires the ability to review the event / experience before ever done or ever learned. (2) Basic (Basic) ie prior knowledge as a foundation for higher capability of basic capabilities such as addition, subtraction, multiplication and division. (3) Critical thinking (critical thinking) is the ability to evaluate and analyze more complex. (4) Creative thinking (creative thinking) is able to create ideas / new ideas that had not been done.

According to [1] Higher Order Thinking skills are categorized into 3 parts: "definitions that I find into three categories: (1) Reviews those that define higher order thinking in terms of the transfer, (2) Reviews those that define it in terms of critical notes thinking, and (3) Reviews those that define it in terms of problem solving ". In this case the definition of higher order thinking skills are categorized into three: (1) as a form of transfer of learning outcomes (2) as a form of critical thinking and (3) as a problem-solving process. While [6] expressed a high level thinking consists of understanding (comprehension), problem solving (problem solving), critical thinking (critical thinking) and creative thinking (creative thinking). [2] states HOTS characteristics as follows: "The characteristics of higher order thinking skills: higher order thinking skills encompass both critical thinking and creative thinking", there are two underlying characteristics HOTS is critical and creative thinking.

Characteristics HOST expressed Resnick (1987: 3): "Higher order thinking skills is non algoritmic, complex, Often yield multiple solutions, Involved nuanced judgment, involves aplications of multiple criteria, Often involves uncertainty, involves self-regulation of the thinking process, involves imposing meaning, effortful ". This means HOTS has the following characteristics: unstructured step - step process, is complex, many of the solutions, involving variations in decision-making and interpretation, many criteria and more effort in doing it. [2] states that: "Higher order thinking skills Contribute to academy achievement". HOTS can be said to support the academic achievement of students.

Furthermore, [3] states: "Higher order thinking Occurs when a person takes new information and information stored in memory and interrelates and or rearranges and extends this information to Achieve a purpose or find possible answers in perplexing situations". So think high tigkat can occur when someone takes and stores the information in his brain and process well and extend that knowledge to reach the goal and immediately find the appropriate answer. According to [23] refers to the cognitive realm of Bloom's taxonomy consists of six levels: 1) Knowledge (knowledge): the ability to remember the material they have learned from the experience of learning. 2) Understanding (compprehension): the ability to grasp the subject matter can be words, numbers, explaining causation. 3) Applications (application): the ability to use the subject matter that has been learned through the experience of learning to the circumstances and conditions that are more concrete. 4) Analysis (analysis): ability to break down the material into parts sehigga organizational structure of matter can dimegerti, 5) Evaluation (evaluation): the ability to take a decision to give an assessment or value judgment on a subject matter in accordance with the objectives. 6) Create (create) is able to make a product / idea either the formulation or form tools.

Level think high-level visits of the cognitive domain Bloom's taxonomy of time at the level of analysis, synthesis and evaluation, meaning the new taxonomy HOTS this to the level of creation. Associated with the revised Bloom taxonomy, is the higher - order thinking is the ability to think from analyzing aspects to creating. The following phases of Higher Order Thinking skills according to [24]:

1) Analysing: involves breaking material into its constituent parts and Determining how the parts are related to one another and to an overall structure. This means that learners fragmenting learned information into its parts in order to obtain information that he can be understood as well as possible. The activities can be grouped Analysing: differentiating, Organising and attributing.
2) Evaluating is defined as making judgments based on criteria and standars. Learners make decisions based upon deep reflection, critique, and assessment. The activities can be grouped evaluating: Checking and critiquin.
3) Creating have students make a new product by mentally reorganizing some elements or parts into a pattern or structure not present before Cleary. Learners mengkreasi new ideas by utilizing previously learned information. Thinking activities that can be categorized aspects of creating: Generating, Planning and Producing.

Critical thinking according to [25]: "critical thinking is the ability to a make rational decisions about what to do or what to believe". that argument is expected for students in a lesson can always respond to critical issues. In addition [26] states that: "critical thinking is a deep thinking process, the which helps us to understand what may be right or wrong. It is analyzing our past experiences and it helps us to resolve situations ". Then [27] states that: "critical thinking is reasonable reflective thinking focused on Deciding what to believe or do". This means that critical thinking is reasonable and reflective thinking focused on determining pa trust and what to do. Creative thinking is not separated with activities - activities that lead to a person's creativity, in the opinion [28] states that: "creativity is pusposeful and involves effort to the make something better, more meaningful, or more beautiful. Meaning: creativity is a goal that involves an attempt to create a job, create a better, more meaningful or more beautiful. On the other hand think creatively defined by [29] stated that: "creativity is the capacity to create, to produce new things". This means that creativity is the ability to create, to produce things - new things. Trying to think creatively is not easy, a creative thinking must dare to fail and try to continue to find new ideas.
From the above it is creative thinking is the ability to think for someone to develop the power of reason, thus bringing forth ideas - new ideas that can be used to solve the problem.

Based on the theory study mentioned the Higher Order Thinking Skill or higher level thinking skills is the process of thinking skills in depth and widespread that involves processing seacara information critically and creatively in the face and solve problems that are kompleks.Soal - math problems in addition to test memory and the understanding and application must also be able to test learners up to level HOTS or can test the process of analysis, evaluation and creative. These questions can be designed with the teacher to see the indicator higher order thinking skills that have been formulated before associating it with a verb that included cognitive operations such as analyzing (C4), evaluating (C5) and creates (C6). Here's a list of verbs operations that can be used to form the matter at the level of higher order thinking skills.

Tabel 3.8 Verbs operations of level C4, C5 dan C6 [30]

Analyzing (C4)	**Evaluate (C5)**	**Create (C6)**
differentiating Organize attribute	Check criticize Prove	Build Plan Produce

diagnosing detailing analyze detecting tie Separate	Maintain Validating Support project	Combine devise Reconstruct Make Create abstracting

If the five indicators associated with the verb HOTS operations on HOTS indicator will be formed as follows:

Table 3.9 Gratings Higher Order Thinking Skills

No	Aspects HOTS	Indicator	Alternative operational verbs that can be used
1.	Critical thinking	Linking the relevant information in accordance with the focus of the problem.	Analyze, select, define, combine and categorize
		Assessing the quality of the precision of an idea / ideas.	Distinguish, compare, predict and assess,
		Detecting the presence of consistent and inconsistent data or information received along with good reason.	Prove and criticize.
2.	Berpikir Kreatif	Develop knowledge of the ones to form new knowledge.	creativity, planning, constructing, designing, finding
		Being able to make a conclusion in accordance with the focus of the problem	Generating and making

B. Why choose PBL?

Characteristics of problem based learning that prioritizes real problems in learning, learning is collaborative, communicative, cooperative and inspiring, train students to learn independently and responsibility, to stimulate the curiosity of students in the investigative process and utilize learning resources are varied [31], [32] , [33], [34]. Based on constructivism understand that learning is student center and student should be able to construct his own understanding in building schemes - schemes in mathematics. Problem based learning approach designed to assist students in the learning process of mathematics. Problem based learning approach utilizes real context of learning so as to make the students better appreciate the usefulness of mathematics dikehidupan day - her day, and familiarize students in solving complex problems that require higher-level thinking processes of students. But not all the problems in mathematics can be contextualized, so the use of problem-based learning, must be clever - clever teachers to pick and choose the material characteristics corresponding to problem-based learning. Problem-based learning when viewed from characteristics is appropriate when applied in the study of mathematics, because mathematics is essentially abstract so as to comprehend the students need to approach the real context in order to be meaningful and useful mathematical material. The advantages of problem based learning according to [31]: (1) it develops students problem - solving skills, (2) it develops sociability level and communication skills, (3) it develops students high-level thinking and critical thinking, (4) it united theory and practice, (student acquire the skills of time management, focusing, the data collection and evaluation report preparation. step - step problem-based learning, namely:

Table 1.1 Steps of problem based learning

No	Steps	Learning activities
1	Presents a problems	Teachers presents problems associated with real world context
2	Merencanakan strategi	Students on the settlement plan that has been accepted
3	Melakukan investigasi	Student and his group find and use various sources, both from books, the Internet or other sources that support problem solving
4	Presenting the works	Processing data later Students present the results of discussions that have been in if the group
5	Evaluate	Students reflect on the results and the process of problem-solving

C. Role Important Scientific Approach

Adopt a scientific approach of the scientific method, prior to be studied more deeply about scientific then we need to know what science is ?, Scientific involve all knowledge contained therein, according to [15]: "science is the activity the which aims to further our understanding of why things happen as they do in the natural world ". The point is that science is an activity that aims to expand / develop an understanding of why - it happens as it happens in nature. From this scientific opinion teaches us to think why something is happening ?, and why? then what about the solution of the problems which have occurred ?. From here students are encouraged to think radically and critically. Experts have different versions - depending on the definition of the scientific method. [35] states that: "scientific method is oversimplified and given too much precedence in science teaching. The version presented here is more complex, allowing for divergence from a set of specific rules ".

According to [16] of the scientific method is a scientific method often used by scientists to analyze the problem and found a solution scientifically. Then, according to [35] states that: "The" scientific method "seems to be an insignificant part of science in a system where the essential finding may be withheld if the" right "answers are not forthcoming". The meaning of this quote is the scientific method seems to be an important part of the science in a system to find the correct or tidaknay an opinion / answers that are useful in the present life and future. The scientific approach used in the curriculum K13 now basically refers to the scientific method used by scientists to study the problem of scientific excellence approach saintific namely the advantages of encouraging and inspiring students to think critically, to inspire learners are Able to think hypothetically see the different, similarities and link to one another on the substance of learning materialsLangkah in scientific approach, namely:

Tabel 1.2 Steps of Scientific Approach

No	Tahap	Aktivitas pembelajaran
1.	Obseving	Seeing, hearing, reading, listening (sign and instrument)
2.	Questioning	Asking questions of a factual question to the question hypothetical. Beginning with the guidance of teachers to independently
3.	Assocciating	Determining the necessary data from questions Specifies the data source either from books, the Internet and books other than textbooks.
4.	Reasoning	Analyzing the data into categories, define data

		relationships, concluded from analysis of data from the data structure that is simple to the complex
5.	Communicating	Delivering results conceptualization in writing, orally or pictures and diagrams.

III. CONCLUSION

Based on the characteristics and advantages of each of the two approaches, problem-based learning and scientific approach can both be used as an alternative approach to learning that can improve students' higher order thinking skills, especially in mathematics. Theoretically and supported by the results of relevant research, the problem-based learning is more effective than a scientific approach, it is because the problem based learning using real context in the learning process, so that students can imagine what will be learned.

The Excellence of Realistic Mathematic Education based on Gardner's Multiple Intelligences Theory through Mathematical Connection Ability

Aris kartikasari[1], Rita suryani[2]
[1]Universitas Negeri Yogyakarta
[2]Universitas Negeri Yogyakarta
Ariskartikasari25@gmail.com

Abstract—The aims of learning mathematics is to develop various aspects. One of them is cognitive. One important ability of students'cognitive aspect in learning mathematics is mathematical connection. Therefore, we need a method to develop student's mathematical connections. In mathematics, one method that can be used to develop student's mathematical connection is RME (Realistic mathematic education)-based Gardner's multiple intelligences (MI). RME can be defined as an approach in learning mathematics using realistic situations or problems in the learning situation so that students understand mathematical concepts. In RME-based multiple intelligences by Gardner, teachers provide realistic problems and diverse learning activities in every meeting. How RME-based Gardner's MI can develop students' mathematical connections in mathematics? This paper will give an explanation through the study of literature.

Keywords: *mathematical connection, realistic mathematic education, Gardner's multiple intelligences*

I. INTRODUCTION

One of the efforts to improve the human resources quality is education. Learning in school is way to realize it. One of the compulsory subjects taught in school is mathematics. In fact, the acquisition of Indonesian student in math scores is low. Based on the results of the Programme for International Student Assessment (PISA) in 2012, Indonesia ranks 64 out of 65 participating countries with an average acquisition in mathematics is 375 [2]. PISA is intended for students in the age range of 15 years.

National Council of Teacher of Mathematics state 5 standard reference processes that need to be studied in mathematics, i.e mathematical problem solving; mathematical reasoning and proofing; mathematical communication; mathematical connections; and mathematics representation. One of the skills that students need to have in learning mathematics is the mathematical connection. Therefore, it is very possible that the low math achievement of students is caused by lack of mathematical connections. Students with high math connection capabilities will easily solve a math problem because basically the mathematical concept has been linked one to another.

There are many things that can be done by teachers to improve student mathematical connections. One of them is learning approach. In choosing a learning approach, teachers need to pay attention on student characteristics. Realistic Mathematics Education (RME) approach is still relevant to be applied for junior high school students who are the concrete operational thinkers or even just starting to formal operational thinking [4]. RME is a math learning approach which is first introduced and developed in the Institute Frudhental Netherlands in 1970. This learning approach originates from two main ideas of Hans Frudhental i.e mathematical problems should be linked to realistic context and mathematics as a human activity.

In addition, each individual in the class has a variety of intelligence that can not be overlooked in learning. There are students that are easier to learn with music, some of them like learn mathematics with pictures, some like to learn in groups, and so forth. It is associated with Howard Gardner's theory on MI.

Learning using Realistic Mathematics Education approach based on Multiple Intelligences theory needs to be applied. RME is expected to increase mathematical connection ability and multiple intelligences theory makes students enjoy studying mathematics, so it is easy to accept.

ISBN 978-602-74529-0-9

Theoretically, how could Realistic Mathematics Education based on the theory of multiple intelligences develop students' mathematical connection capability? The explanation on the matter is expected to give an idea how to develop students' mathematical connections through Realistic mathematics education approach based multiple intelligences theory as well as how to implement it in the teaching learning mathematics.

II. Discussion

A. *Realistic Mathematics Education (RME)*

RME is one of mathematics approaches which was first introduced and developed in the Institute Frudhental the Netherlands in 1970. The learning approach originates from two Hans Frudhental's main ideas that mathematical problems should be linked to realistic and mathematics as a human activity. This approach uses realistic problem to help students construct mathematics concepts. The problem is not always the realistic one that exists in the real world (real world problem) and can be found in student's daily life. A problem is called realistic if it is imaginable on student's mind. Meanwhile, as the activity, students should have the experience or the opportunity to do the experiment to construct their knowledge [5].

Learning using RME should contain the characteristics of the approach. Treffers in [6] mentioned 5 characteristics of RME, as follows:

1. Context Use

   Context is a bridge for students to understand mathematical concepts. Context used as a realistic problem should be imaginable for students.
2. The use of mathematical models for Progressive mathematization

   Refers to [7] RME is a model of learning that guides students from the informal into formal knowledge. Students face contextual issues then a model is developed based on the issues. Next, the model will be developed using mathematical reasoning in order to obtain formal mathematics.

   The process above is called mathemazation. [8] argues that the mathematization is the process leading to the mathematical concept from the real problems which are close to students' lives. There are two types of mathematizations: *When this actively of mathematizing applies to a subject matter of reality, we call it horizontal , and when it applies to a mathematical matter one speaks of vertical mathematization.*

   It can be concluded that the mathematization is a process of informal to the formal mathematics. Based on the classification, horizontal mathematization directs students to identify the real context and translate it into mathematical language to make it more understandable to complete. Vertical mathematization also rests on contextual problem until it can arrange a specific procedure to resolve the problem without starting by context.
3. The Utilization of Student's Construction

   Mathematics is not a finished product. Students are given the opportunity to construct knowledge through exploration. The results of their findings are the basis for building a mathematical concept.
4. Interactivity

   Group activities, the indirect negotiations, and discussions are very important activities in the process of knowledge construction. It is an informal method for students in acquiring formal knowledge.
5. Intertwining

   Single mathematical concepts are not enough to apply the concepts and problem solving. Intertwining is needed in solving mathematical problems.

B. *Multiple Intelligences(MI)*

Intelligence is the ability to apply knowledge and experience to face the challenging tasks flexibly [4]. Howard Gardner [9] stated that, *Intelligence is the human ability to solve problems that are valued in at least one culture*. Furthermore, refers to [10] states that MI are the ranges of students' skills and talents to solve problems in learning process. In conclusion, intelligence is the ability to solve the problem that could be different from one person to another. This is talent as well.

Howard Gardner, in his book "Frames of Mind", suggests that there are nine kinds of intelligence of human beings that form multiple intelligences. Here are nine multiple intelligences, the characteristics, and ways to employ in teaching-learning process:

1. Verbal-Linguistic intelligence
   People who have this intelligence tend to have a high ability in reading, writing, and talking. In mathematics, students can be encouraged to understand certain concepts through poetry.
2. Logical-mathematical intelligence
   People who have this intelligence have the ability to make mathematical calculations, deductive and inductive reasoning, build logical relationship, to propose hypotheses, to solve problems, to think critically, and to understand the numbers, geometric shapes, and abstract symbols.
3. Visual spatial intelligence
   Visual spatial intelligence is the ability to make visual representation in mind, or the ability to dream, to imagine, to think with drawings, lines, shapes, and so forth. Teachers can present learning materials in graphs, pictures, and diagrams to make visual spatial students more easily understand.
4. Musical-rhythmic intelligence (musical intelligence)
   Musical intelligence is related to rhythm, sound, tones, and music. Children who have musical intelligence has ability to play an instrument, to sing a song and write songs. To facilitate students with musical intelligence in learning mathematics, teacher can introduce the mathematical material through song.
5. Bodily kinesthetic intelligence
   Bodily-Kinesthetic intelligence is an ability to move, make gesture and facial expression, using the effective coordination between brain and body, and produce all or part of the body movement. In mathematics, this intelligence can be facilitated with a hands-on activity and by letting the child learn with some learning instruments.
6. Intrapersonal intelligence
   Interpersonal intelligence is the ability to understand and distinguish emotions, aspirations and needs of the environment. To facilitate this intelligence, teacher can use some cooperative model learning.
7. Intrapersonal intelligence (intrapersonal intelligence)
   According to Gardner, intrapersonal intelligence is the kind of intelligence that is the most important in life. It is enables person to understand and be responsible with theirself. Students with this intelligence can be given the opportunity to learn on their own first before learning in groups.
8. Naturalistic intelligence (naturalist intelligence)
   It is the ability to identify and find objects in nature and thinking life form. Outdor learning is one way to facilitate students with this intelligence.
9. Extensialist Intelligence
   Ekstensialist intelligence is the ability to question everything. Intelligent people tend to question why something happens, the reason of some event, and curious about everything. To facilitate the students with this intelligence, teachers need to understand and prepare the answers of teaching materials [11].

C. Mathematical Connection

Mathematics is often seen as as an unrelated set of skills or activities. A person who visualizes math only as a collections of facts, capabilities, and procedures will find it hard to achieve a deep understanding of mathematics. Mathematics is not a collection of separate topics, but a thorough knowledge and mutual connections [12]. Refers to [3] defined five standard capabilities that must be possessed by students in learning mathematics: problem solving, reasoning, communicating, making connections, and making representations.

Mackanong in [13] states that "mathematical connection was learners' abilities to link the previous of their mathematics knowledge and problems gained from classes to the current problem or situation with the which they were dealing." This means that the mathematical connection is the ability to connect the mathematical knowledge they already have in long-term memory into a situation or problem they are facing.

Hiebert & Carpenter in [14] suggest that making a connection process in mathematics is the core of developing mathematical understanding. Teacher should facilitate students to make connection so that students can find meaning in learning. Refers to [15] state that a student will actually have a relational understanding (knowing what to do and why) in the learning process if they do not just memorize or remember the material being taught, but also can connect the concepts or new procedures with ideas owned by the students beforehand. Mathematical connections allows students and teachers to discover mathematics in daily life, especially everything related to the life and interests of students, the relationship between mathematical concepts and mathematical relationships with subjects or other disciplines [16].

Based on [17] argues that the correct relation can build conceptual understanding. The more powerful students make connection between interrelated concepts, then the understanding gained will be deeper and richer. In essence, a person will gain an understanding of new concepts and build it through connection with the previous concept. The person will add and develop an understanding of the new concepts as well.

Refers to[3] states that a person is able to perform mathematical connection, if: (a) be able to recognize and use connection among mathematical ideas; (b) understand how mathematical ideas are interconnected and built on one other to produce a coherent result; (c) recognize and apply mathematics in contexts outside of mathematics.

According to [18] study of mathematics will be effective if the learning process facilitate students to do some of the connections as follows:

1. Establishing a connection between student's initial knowledge with concepts and new abilities.
2. Connecting intuitive knowledge with formal mathematical/ abstract.
3. Connecting several mathematical representations, concrete activities, the language of mathematics, and certain symbols.
4. Connecting between topics in mathematics.

The characteristics of people who have mathematical connection ability can be identified, as: capable to connect mathematical concepts or mathematical ideas that students already have into mathematical problems being faced, capable to connect some concepts or mathematical ideas that students already have into the contextual issues that related to daily life, and capable to connect concepts or mathematical ideas that students already have into the problems associated with other disciplines. From some of these characteristics, the mathematical connection indicators are as follows:

1. Connecting concepts or mathematical ideas with mathematics problems.
2. Connecting concepts or mathematical ideas to problems in the context of everyday life.
3. Connecting concepts or mathematical ideas to problems in the context of other disciplines.

D. The Excellence of Realistic Mathematic Education based on Gardner's Multiple Intelligences Theory through Mathematical Connection Ability

RME has five characteristics. One of the characteristtic is the ability to connect the realistic problem with the students previous knowledge. RME approach that emphasizes problem solving can not be separated from the connection process. RME with realistic problems require students to be able to resolve the problem by changing into a mathematical form, and connect the problems with the mathematical concepts owned by the students. Multiple activity based on multiple intelligences will help students develop the mathematical connection capabilities. It aims to connect their activities with the concepts they learn. The activities will vary significantly if students can relate to the mathematical concepts that are being or have already learned.

According to [19] argues that to facilitate students connection, mathematic teacher should be able to encourage students to undertake investigative activities, link mathematics, to facilitate the students to be able to select the appropriate method to give a reason and idea, and to judge their decisions in resolving a problem. RME is the best approach because it enables students to explore, to connect concepts with methods/strategies as appropriate, as well as to provide ideas in group discussions. In conclusion, RME approach based on multiple intelligences theory can promote students mathematical connection.

Here are the steps that teacher can practice in the teaching and learning mathematics.

1. Understanding realistic problem
   Teacher given the realistic problem to be understanding by the students. The realistic problem should be in multiple context. Multiple context will facilitate the students with multiple intelligences. In this phase, teacher give a simple explanation about the problem to the students.
2. Solving the realistic problem
   Teacher can facilitate intrapersonal or interpersonal intelligences in this phase. Teacher give a chance for students to think individually or by group discussion to solve the problem, and using students logical mathematical intelligences to make mathematical modeling about the realistic problem to get the solution. In this phase, students have to make connection about the problem and the concept they should use to solve the problem. This also can promote students mathematical connection.

3. Comparing Result and Making Conclusion
   In the last phase, students have to present their discussion in the class, comparing with the other, and teacher clarifying the correct result. And last, the students and teacher making conclussion about the topic, what they have learned. This phase is appropriate with the interactivity principal of RME.

Here is the example of realistic problem about area of circle that related to the the concept of area of rectangular and the concept of arithmetics.

"*A rectangular garden in Yogyakarta have dimension 15 meter × 9 meter. There is a fountain pool in circle shape in the center of the garden. The diameter of the pool is 9 m. That garden will be palted with the grasses except the pool. If the cost needed is Rp105.000,00 for every 1 meter square, determine the whole cost to plant the grasses.*"

To solve the problem above, students have to connect the real problem to the mathematical concepts, and also have to connect the concept of area of circle with another concept, such that area of rectangle and social arithmetics.

III. CONCLUSION

Realistic mathematics education approach based on Gardner's multiple Intelligences theory can make student's mathematical connection ability excellent. Therefore RME learning progress should contain 5 characteristics including intertwining. That means, one material should be connected with others and students should have mathematical connection ability to do that. The mathematics materials are found by an exploration and mathematization progress, so they will not memorize only but also understand. Furthermore, learning process based on Gardner's multiple intelligences will make students enjoy because they learn with various activities they love.

Characterization of Mathematical Connections in Calculus

Arjudin[1], Akbar Sutawidjaja[2], Edy Bambang Irawan[2], Cholis Sa'dijah[2]
[1]Doctoral Program ofMalang State University
[2]Mathematics Department ofMalang State University
arjudin@unram.ac.id

Abstract**—**This paper aims to determine the types of mathematical connections when undergraduate students solve connections problems in calculus, and to describe the characteristics of each type of the connections. The approach of this research is qualitative research with descriptive exploratory method. Itsparticiants were undergraduate students of Mathematics Education Study Program, Faculty of Teaching and Education, University of Mataram in Academic Year 2015/2016. Data of research collected through the connections assignment sheet in calculus and followed up by interview based on the tasks. The study resulted that the type of mathematical connection can be characterized into two types, that are the proceduralconnections and the conceptual connections. Each of these type links two or more topics among some topics in calculus. In the future studies, result of this characterization will bedetailed schematically to describe its process of thinking.

Keywords:*calculus, characterization, mathematical connections.*

I. INTRODUCTION

When learners solve a problems, it was often happened that they already have learned and mastered the knowledge required to solve the problem, but they can't associate or make a connection and use it to solve the problem. Therefore, the ability of mathematical connections needs attention in the learning of mathematics. Mathematical problems solving need skill to connect mastered knowledge relating to the problems encountered.

Mathematical knowledge can be divided into two types, namely conceptual knowledge and procedural knowledge [1]. The core of conceptual knowledge is to understand the relationship between ideas and mathematical concepts. The purest form of procedural knowledge focuses on the symbolism, skills, rules and algorithms used step by step in solving a mathematical task. Learners should learn the concepts at once with the procedures so that they can see the connection.

Concepts, procedures or skills, along with facts and principles identified by Gagne as the direct object of mathematics [2]. While the one of indirect objects of the mathematical is problem solving. Problems are questions that can be understood by learners but can not be answered immediately with a routine procedure that has been known to learners. So a question can be clasified as a problem when the questions give a challenge to be answered and the answer can not be done by a routine strategy. Solve the problem is the process of accepting the challenge to answer the question that is the problem [3]. A problem for college students when administered to elementary level students excluding a problem because the problem will not be understood and will not give a challenge to be answered.

Bruner's connectivity theorem stated that in mathematics every concept related to other concepts. Similarly, between the argument and the other argument, the theory with the other theory, among the topics to the topic, and between branches of the branch of mathematics sholuld be related [4]. Therefore, in order to be more successful in learning mathematics, learners must be given the opportunity to make mathematical connections.

Connection mathematically described by [5] as part of the network is structured like a spider web, "*The junctures, or nodes, can be thought of as pieces of represented information, and threads between them as the connections or relationships*". Mathematical connections can also be described as a component of a scheme or a linked group of schemes in mental network. Reference [6] argued that the characteristics of the scheme is the connection. The more connections, the greater compactness and strength of the scheme.

Studies on the connection mathematical beside conducted in schools are also a lot done in universities [7], [8], [9], [10]. According [11], which examines undergraduate students in pre-calculus course concluded that the subjects had not yet established a connection between algebra procedures and the nature of the underlying numbers. Results of research on the connection in linear algebra carried out by [12] showed that subjects find it more difficult to make the connection between concepts like eigenvalues and eigenvectors and of other parts such as the conceptual basis and the dimension.

Research by [13] on middle school pre-service teachers has resulted five categories of mathematical connections, namely: (1) *categorical*, if the paticipant's explanation relied upon the use of surface features primarily as a basis for defining a group or category; (2) *characteristic/property*, if the participant's explanation for the sort involved defining the characteristics or describing the properties of concepts in terms of other concepts; (3) *curricular*, if the participant's explanation for the sort involved relating ideas or concepts in terms of the impact to curriculum, including but not limited to, the order in which one would teach concepts or topics; (4) *procedural*, if the participant's explanation for the sort involved relating ideas based on a mathematical procedure or algorithm possible through the construction of an example, which may include a description of the mechanics involved in carrying out the procedure rather than the mathematical ideas embedded in the procedure; and (5) *derivational*, if the participant's explanation for the sort involved knowledge of one concept(s) to build upon or explain other concept(s), included but not limited to the recognition of the existence of a derivation.

Results of another study suggests three types of connections, that are referred to the most commonly in relevant literature and in their formal curriculum documents, but in practice their development of "connected knowing" could have been stronger, more frequent and more consistent. The three kinds of connections are the connection between new information and current knowledge, the connection between mathematical concepts, and the connections to everyday experience [14]. The types of connections is in line with the scope of connection standards in the [15], which include recognize and use connections among mathematical ideas, understand how mathematical ideas interconnected and build on one another to produce a coherent whole, recognize and apply mathematics in contexts outside of mathematics.

Study of the source of theory and the previous research results presented above, gave rise to the idea of mathematical research with the theme of connections. The connections studied is considered by knowledge of mathematics that divided into two types of knowledge, namely conceptual knowledge and procedural knowledge. Therefore, research on the characterization of the mathematical connections when undergraduate students solve problems about calculus was conducted. The material of calculus is chosen because it is the core material in mathematics educations program, and a lot of good use in other disciplines as well as in everyday life.

This research is expected to be useful among others, to provide an overview of the undergraduate students about the characterization of mathematical connections, so it can be used as a benchmark to improve problem solving skills. In addition, it is expected to be useful as well as inputs for lecturers or teachers of the importance of undergraduate students making mathematical connections so that it can be taken into consideration in planning and implementing learning.

II. METHOD OF RESEARCH

Type of research is descriptive exploratory study. The participants were six undergraduate students of Mathematics Education Study Program, Faculty of Teacher Training and Education, University of Mataram in Academic Year 2015/2016. The main instrument in qualitative research was a researcher itself [16]. The support instruments are an assignment sheet and an interview guides. The assignment sheets gave a task of connection on calculus in the form some cards with information written on it. Informations on these cards can be facts, a concepts, principles, procedures, or problem about calculus. The cards are considered as nodes that shoul be connected.

The tasknumber 1, contain two cards, consist of information about The Pythagoras Theorem and a point (x, y) at Cartesius coordinate system that satisfy $x^2 + y^2 = r^2$, where $r > 0$.The task number 2 consist of three cards that each contain information about concepts, that are absolute value function, derivative of function, and graph of function. The problem structure of task number 1and number 2 is describedin Figure 1 and Figure 2.

Mathematical connections made by participants are grouped and identified its characteristics. Judging from the type of knowledge conceptual and procedural knowledge, this type of mathematical connection divided into two types, namely conceptual connections and procedural connections. While looking at the material, there are some topics related material, for example: Pythagoras theorem, Cartesius coordinate system, absolute value function, graph of functions, and derivative of fuctions.

In the Fig. 1, a participants that make connection inter nodes by similiraty formula is catogorized as procedural connections, meanwhile if a participants connect two nodes by plotting the right triangle at the

Cartesius coordinate plane that contain the circle with center O and radius r then it is categorized as conceptual connections.

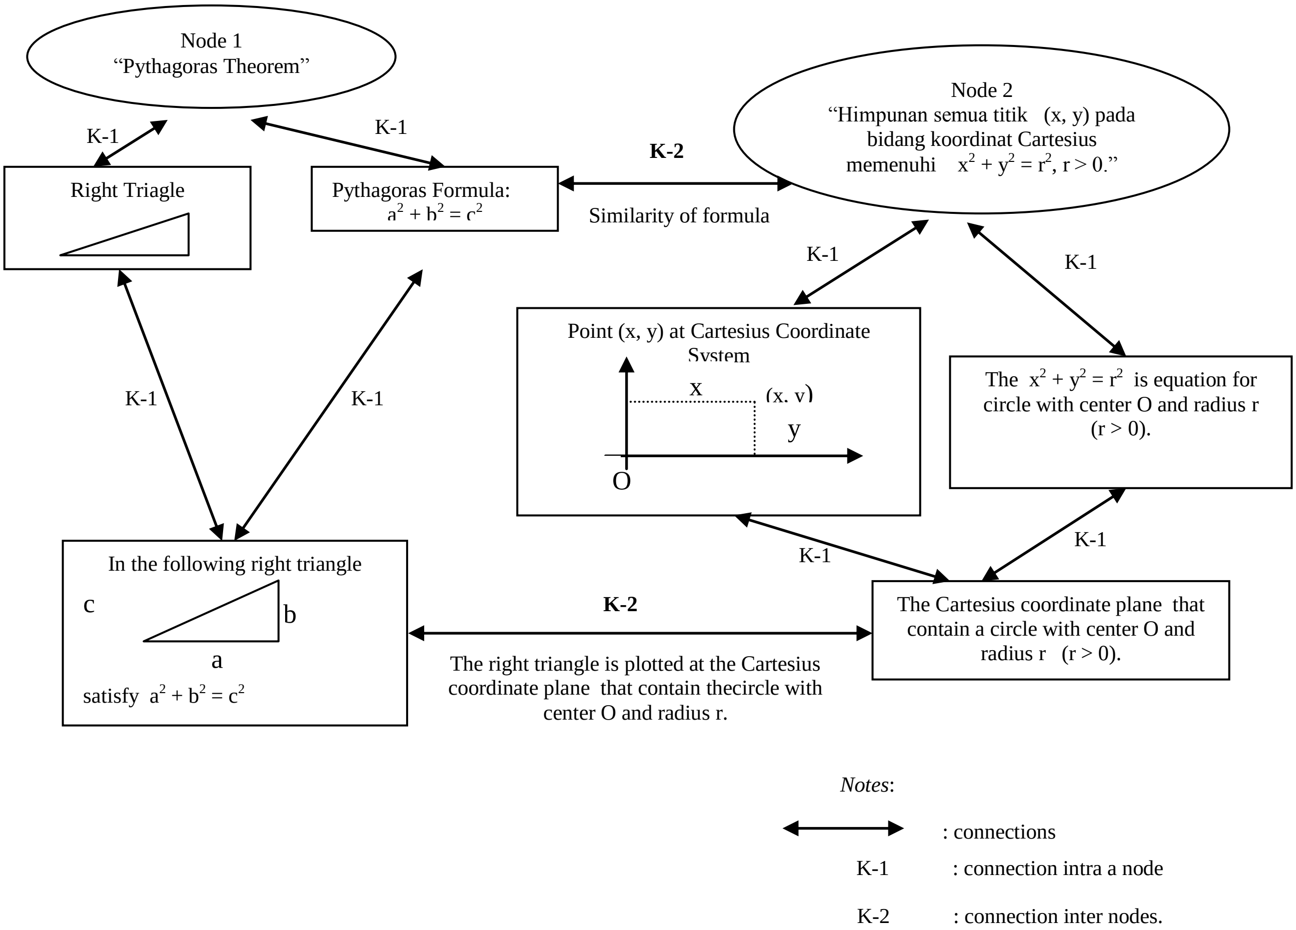

FIGURE 1. THE PROBLEM STUCTURE OF TASK NUMBER 1

In the Fig. 2 below, a participants that make connection inter nodes by compute derivative without consider geometrically interpretation is catogorized as procedural connections, meanwhile if a participants make connection inter nodes by compute derivatives, then consultated with geometrically interpretation is categorized as conceptual connections.The indicators of the type of mathematical connection can be expressed in Table 1.

TABEL 1. THE INDICATORS FOR TYPES OF MATHEMATICAL CONNECTIONS

No.	Type of Mathematical Connections	Indicators
1	Procedural Connection	• To connect the Pythagoras theorem with point (x, y) at Cartesian coordinate system that satisfy $x^2 + y^2 = r^2$by similarity formula. • To connect the absolute value function with derivative of function by count its derivative without consultated its graph. • To connect the absolute value funtion with graph of function by draw its graph without analize it. • Not make connection between derivative of function with tangent slope of function.
2	Conceptual Connection	• To connect the Pythagoras theorem with point (x, y) at Cartesian coordinate system that satisfy $x^2 + y^2 = r^2$by plotting the right triangle at the Cartesian coordinate plane that contain the circle with center O and radius r. • To connect the absolute value function with derivative of function by count its derivative and consultated its graph. • To connect the absolute value funtion with graph of function by draw its graph, then analize it.

ISBN 978-602-74529-0-9

		• Make connection between derivative of function and tangent slope of function, then look smoothness the graph.

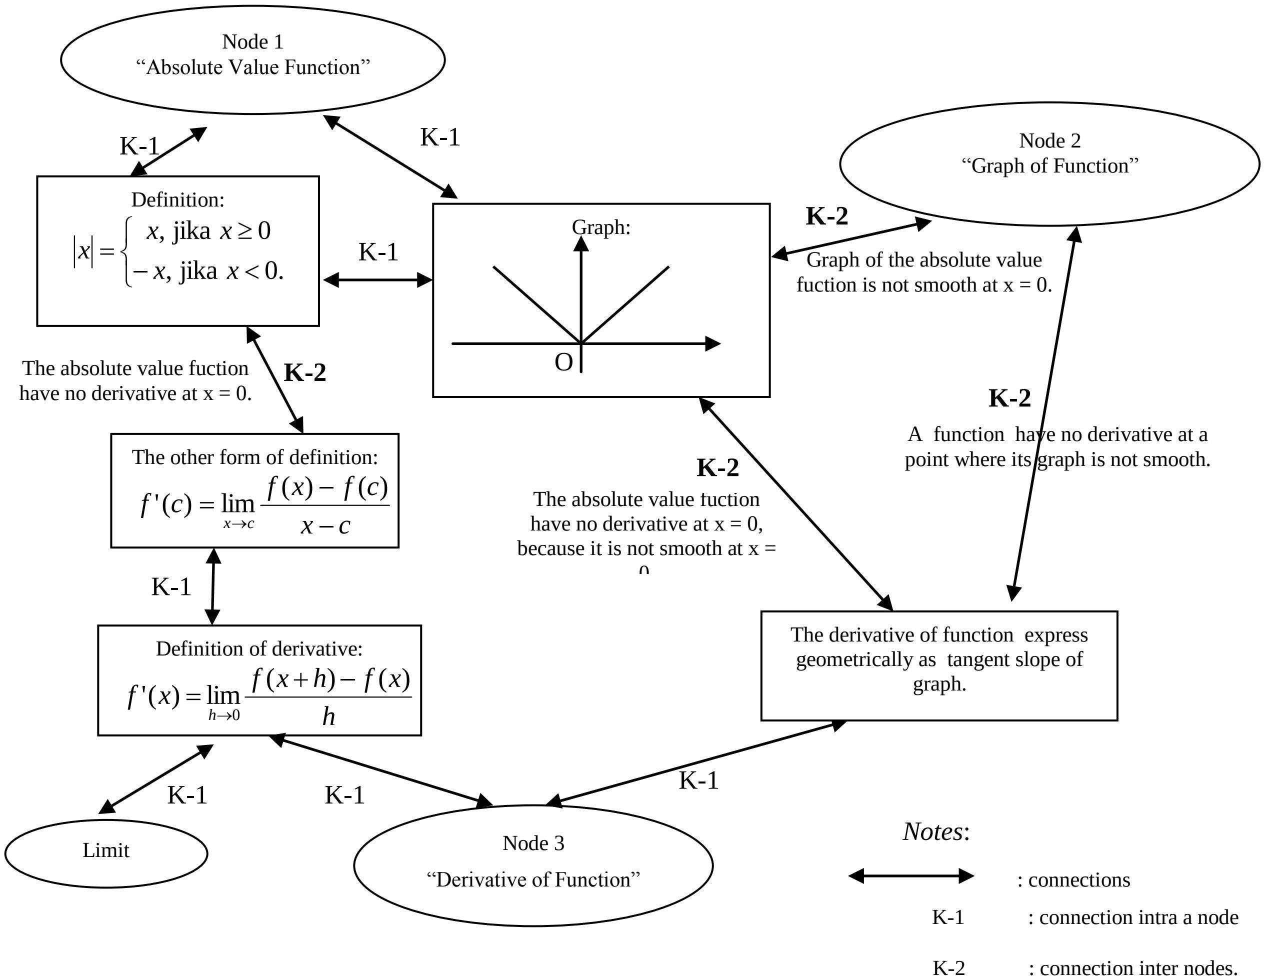

FIGURE 2. THE PROBLEM STUCTURE OF TASK NUMBER 2

III. Result and Discussion

The results of the participants' answers to the connection task recapitulated based on aspects of conceptual connection and procedural connection. There are some topics related to the material, which arePythagoras Theorem and Point in Cartesian coordinate system at task 1, meanwhile material in task 2 include absolute value function, derivatives and graph. Responses of participants is presented in Table 2 below.

Results of analysis of the data resulted in grouping type of mathematical connection, which can be divided into two types, namely conceptual connections and procedural connections. The conceptual connections occurs for participants S1 when make connections between "Absolute Value Function", "Graph of Function", and "Derivative of Function", because after count its derivative,then she draw its graph then analize it, so that can make connection between derivative of function and tangent slope of function or smoothness the graph, as shown in Fig. 3.

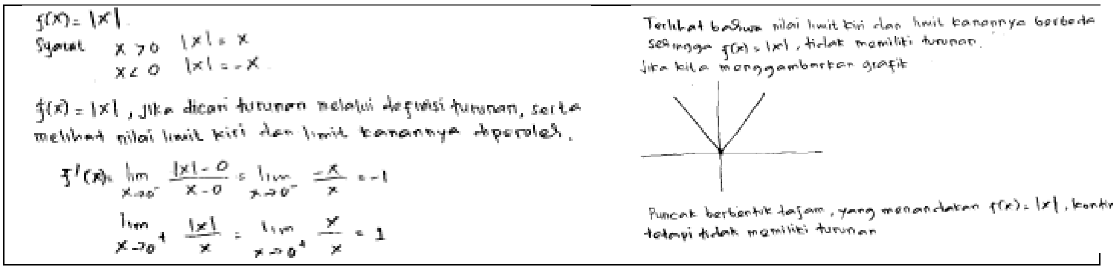

FIGURE 3. PARTICIPANTS' ANSWER THAT CATEGORIZED AS CONCEPTUAL CONNECTIONS

TABEL 2. RESPONSES OF PARTICIPANTS

Participants	Node of Connections	Explaining of Connections
S1	"Pythagoras Theorem" and "An arbitrary point (x, y) at Cartesian Coordinate System satisfies $x^2 + y^2 = r^2$, where $r \geq 0$"	Pythagoras theorem entitled at a right-angled triangle. The right triangle is drawed with O (0,0) and (x, y) as the vertex and sides are respectively x, y, and r.Therefore, the equation $x^2 + y^2 = r^2$ is the form of Pythagoras Theorem, where $r \geq 0$ is distance from original point (0, 0) to point (x, y).
S1	"Absolute Value Function", "Graph of Function", and "Derivative of Function"	Graph of the absolute value function depicted shaped sharply, indicating continuous but has no derivative. The absolute value function has no derivative at x = 0. It is calculated using the definition of derivative obtained limit value of the left and right limits are different.
S2	"Absolute Value Function", "Graph of Function", and "Derivative of Function"	Expressed $f'(x) = \|x\|/x$, but can not give a reason.Graph illustrates the absolute value function sharp angle, signifying nothing derivative in that.But for the general functions, such as quadratic functions, she can not give the interpretation of the derivative in terms of the graph of a function.
S3	"Pythagoras Theorem" and "An arbitrary point (x, y) at Cartesian Coordinate System satisfies $x^2 + y^2 = r^2$where $r \geq 0$"	Pythagorean theorem is the distance of points (x, y) in Cartesian coordinates satisfy $x^2 + y^2 = r^2$, $r \geq 0$. The right triangle is drawed in the Cartesian coordinate system with O (0,0) and (x, y) as a point angles and sides are respectively x, y, and r.
S4	"Absolute Value Function", "Graph of Function", and "Derivative of Function"	The absolute value function is a function that its graph is above the x-axis. Derivative of a function can be illustrated in a graph of a function. Absolute value function is a function that can be derived and the function can be described in a function.

The procedural connections occurs for participants S1 and S3 when make connections between "Pythagoras Theorem" and "An arbitrary point (x, y) at Cartesian Coordinate System satisfies $x^2 + y^2 = r^2$, where $r \geq 0$", because they only look similarity formula without plotting the right triangle at the Cartesian coordinate plane that contain the circle with center O and radius r.Connections between "Absolute Value Function", "Graph of Function", and "Derivative of Function" maked by participants S2 and S4 is categorized as the procedural connections too, because S2 expressed $f'(x) = |x|/x$, but can not give a reason and S4 can not make connection between derivative of function with tangent slope of function. The examples of procedural connections is shown in Figure 4.

FIGURE 3. PARTICIPANTS' ANSWER THAT CATEGORIZED AS CONCEPTUAL CONNECTIONS

IV. CONCLUSIONS

From the results of this study concluded that the type of mathematical connections when undergraduate students solve problems in topics of calculus can be divided into two types, that are conceptual connections and procedural connections. Characterization of each type of mathematical connections in terms of topics related, that are Pythagoras theorem and point at Cartesian coordinate system,as well as absolute value function, derivatives and graph. The implications of this study are expected that lecturers need to provide problem-solving issues that are non-routine and requires undergraduate students to explore mathematical ability as a whole in order to make the mathematical connections which is a tool in problem solving.

***Abstract*—** Knowing the information from the reality on the school that the mathematical reasoning students in class X is still less. Motivation and activity of students in the learning of mathematics is also less. Based on this background the purpose of this study is to determine whether there is influence the activity of students using problem-based learning in the ability of the mathematical reasoning students, whether in mathematics using problem-based learning can achieve the criteria completeness minimum (CCM), and to investigate the activities of teachers and students during the learning takes place. The method used in this research is the experimental method. In doing in class X SMA Negeri 1 Jalaksana Brass in the academic year 2013/2014. Selection of the samples in this study conducted with a purposive sample technique to make the class X-3 as the experimental class using problem-based learning and class X-2 as the control class by using conventional learning with expository. The instrument used for data collection in this study is an essay test in accordance with the indicators of mathematical reasoning to the material Exponent, The Roots and logarithm. Tests are given consists of 7 questions of reasoning. The results showed a positive effect of the activity between the use of problem-based learning to students' mathematical reasoning abilities. This is evidenced by the size of the acquisition value over the average posttest experimental class than the control class. Knowing the positive value of the coefficient update equation linear regression model that explains the meaning of the positive value of the activity of students in problem-based learning process a positive influence on students' mathematical reasoning abilities. The achievement of CCM using problem-based learning.

Keywords: *influence, problem based learning, mathematical reasoning.*

I. INTRODUCTION

In the era of global information, people are required to have the ability to acquire, select, manage and act on that information to be used in a dynamic life and full of challenges and competition. A dynamic life demands that we have a critical ability, this ability can be developed through learning mathematics.

Mathematics in schools (Depdiknas, 2006) are (1) train the way of thinking and reasoning to drawing conclusions. (2) develop a creative activity that involve imagination, intuition, and discovery by developing divergent thinking, original, curiosity, make prediction and expectation, as well as trial and error. (3) develop the ability to convey information and communicate ideas. The explanation can be said that there is a close relationship between the formation of human character which is expected by the learning of mathematics, so that the learning of mathematics must be given to all students without exception to be trained to think logical, analytical, systematic, and creative.

Learning mathematics based Education Unit Level Curriculum current is intended that learners have the capability of understanding the concepts, reasoning, problem solving, and mathematical communication. By not ignoring other skills, reasoning ability plays an important role in the learning of mathematics. The ability to reason is not only required students as they learn mathematics and other subjects, but also is needed for every human being at time when its own decisions. Reasoning ability is also necessary in order to achieve better results in solving a mathematical problem. Therefore, we need to realize that the reasoning skills should be ~~is~~ grown within the individual student.

Based on discussions with the author of a mathematics teacher in class X SMA Negeri 1 Jalaksana Brass obtainable information that mathematics learning activities include students have difficulty to solve problems that require analytical reasoning. A number of students who have understood the theoretical mathematical topic was experiencing difficulty when questions or problems presented in the form of analyze. Reality on the ground students simply memorize concepts and less able to use these concepts when they have a problem in real life. According to the survey, several high schools in West Java Kuningan area, generally the teacher explains concept be informative, giving the example problems, and provide exercises. The tradition of teaching such as this is a common characteristic for teachers implement mathematics in Indonesia and could be said that conventional mathematics.

Problem-based learning model is expected to be a solution or alternative in this research for teachers in order to improve students' mathematical reasoning abilities. Based on the above, the authors are interested in conducting research on "The Effects of Problem Based Learning Mathematical Reasoning Ability Of High School Students (Research Experiments in Class X SMAN 1 Jalaksana Brass)."

II. RESEARCH METHOD

This study used a study design shaped pretest-posttest control group design. In accordance with the study design used, this research involves two classes of experimental class and control class. To saw the effect of problem-based learning to students' mathematical reasoning abilities pretest and posttest in both classes. The design used appropriate (Sugiono, 2012: 116) could be described as follows.

R O1 X O2

R O3 O4

Information:

R: The sample study were randomized (random)

O1: pretest experimental class

O2: posttest experimental class

O3: Pretest control class

O4: posttest control group

X: Treatment of experimental class

The study population consisted of ten classes with all students numbered 400 students. Based on information from the school, students SMA Negeri 1 Jalaksana Brass had diverse capabilities. The sampling technique in this study used purposive sampling techniques. Based on the opinion of Sudjana (Sudjana, 2005: 168) "The definition of a purposive sample (sample purposive) that sampling based on individual considerations or consideration of researchers." Since the measurement is a measurement of high-level analyze so that researchers would use the excellent class. So that became a purposive sample in this research is class X-3 were used as experimental class learning used problem-based learning with the consideration that the class had an average UN high mathematics, so that assumed to have good reasoning ability. Data analysis was performed in order to draw conclusions with regard to the problem to be solved in the research. The data obtained data about students' mathematical reasoning abilities

Here are the steps performed in the data analysis.

1. Calculate descriptive statistics of mathematical reasoning ability by pretest and posttest, and calculates a score initial reasoning skills and reasoning abilities final score in each class were selected as sample.
2. To determine the increase in students' mathematical reasoning abilities after learning test was used Gain normalized.

3. Perform data normality test pretest, posttest and Gain normalized.
4. To test the homogeneity of data pretest, posttest, and Gain normalized.
5. To test the difference between two average.
6. Scaterplots observations on the value of the activity with the value posttest in the experimental class.
7. Perform simple linear regression test.
8. observations on scaterplots residue obtained from the simple linear regression model.
9. Perform calculations mastery learning outcomes could be seen from the posttest that have reached KKM.

III. FINDING AND DISCUSSION

After collecting the data, the data obtained in the form of initial test scores and final test scores, which average could be seen in Table 1.

Table 1

Descriptive Statistics Data Results pretest and posttest

Statistical Data	Experiments		Control	
	Pretest	***Posttest***	***Pretest***	***Posttest***
Number of Students	40	40	40	40
Largest Data	24	94	24	92
Data Smallest	00	10	00	00
Range	24	84	8,08	27,06
Average	11,72	65,97	11,22	56,07
Standard Deviation	6,88	25,47	8,08	27,06
Variance	47,43	649,20	65,410	732,533

Knowing the information from the test results influence (simple linear regression) showed that there is a linear relationship between student learning activities using problem-based learning with mathematical reasoning abilities of students in the experimental class. R-square values obtained or R2 = 0.817 = 81.7%. These values indicate the size of the goodness of fit between the regression model or data obtained from a class that implements problem-based learning. The R2 also shows the diversity of data able to be explained by the regression model $Y = \alpha + \beta x$. In addition there is a 28.3% variable diversity of data that is not explained by other variables in addition to the attitude shown in the process of problem-based learning.

Information obtained from the equation regression model received is $Y = -170 + 2{,}962x$. The linear regression model equation could be known the acquisition value of a positive coefficient of 2.962. This shows that the influence of the activity of students in problem-based learning activities had a positive influence on students' mathematical reasoning abilities. This means more active in the learning process, the higher the students' mathematical reasoning abilities.

From the acquisition of information regrsi linear model equations are received and information value of R2, it could be seen that there are positive influence between problem-based learning with students' mathematical reasoning abilities.

Teacher activity observation results are presented in Figure 1 as follows.

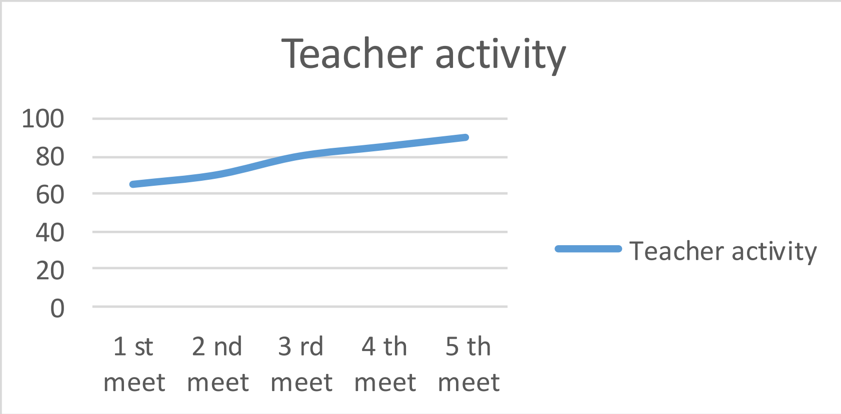

Figure 1 Teacher activity observation results

Knowing the information from Figure 1 and data analysis observation result, the value of teacher activity from the initial meeting until the end of the meeting has increased dikatagorilan good.

Then, from the results of observations on the implementation of problem-based learning at the first meeting until the fifth meeting, the information obtained at the first meeting activity value of teachers is 35 and the percentage is 70%, the second day of the value of the activity of teachers is 39 and the percentage is 78%, whereas the third day activity value of teachers namely 42 and the percentage is 84%. On the fourth day activity value and the percentage of teachers that is 45 to 90%. On the last day that the fifth meeting of the value of the activity of teachers is 47 and the percentage is 94%.

At the initial meeting measures problem-based learning activities that have been going on for quite match the characteristics of problem based learning has been established, but this has not been maximized. However, to further the implementation of learning activities, measures problem-based learning has been more leverage, as seen in the increase in the percentage of activity the teachers obtained.

Student activity observation results are presented in Figure 2 as follows.

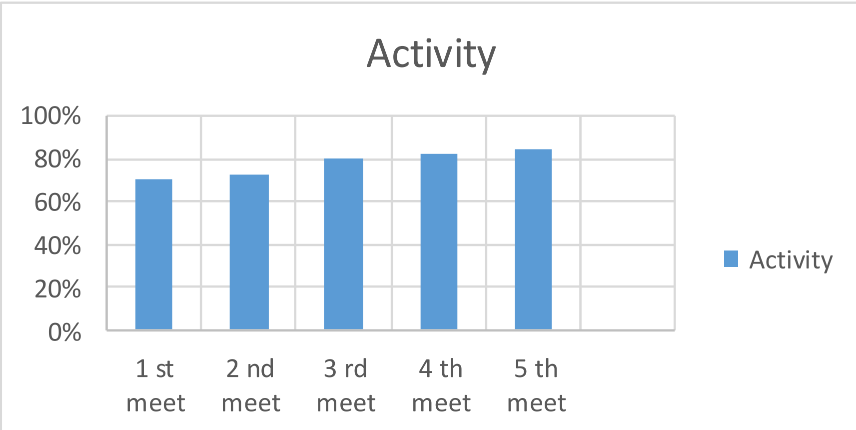

Figure 2 Observations on implementation

Knowing the information from Figure 2 that the results of observations on the implementation of problem-based learning carried out in the experimental class obtained average value activity at its meeting also increasing, with the first meeting obtained a value of 2.81 or 70% were terkatagori good. The second meeting enhancement experienced by 4% of obtaining a value of 2.96 or 74% were good category. The same thing also at the third meeting, namely an increase of 6% from the first meeting, the acquisition value at the third meeting soon is 3.2 or 80% were good category.

Acquisition value at the fourth meeting an increase of 2% from the third meeting, namely 3.33, or 83% were categorized either. At the fifth meeting or end the meeting there was an increase from the fourth meeting of 2%, is to obtain a value of 3.41 or 85% were categorized either. Of all the activities in every meeting obtained by the average value of the activity of 3.15 or 76%, which means the problem-based learning activities held in the experimental class good category.

IV. CONCLUSION AND RECOMMENDATION

A. *Conclusion*

1. Based on information from the analysis of research data shows that the mathematical reasoning abilities of students in the experimental class in mathematics learning problem-based learning used higher when compared with the control classes in mathematics menggunakkan conventional learning is expository. This can be demonstrated by the increase in the average scores of 54.23 to 44.85 for the experimental class and control class, so there is a difference between experimental class control class is 9.38. Aside from the average value of the test, students' mathematical reasoning ability difference between the experimental class and control class can also be seen from the average score of N-Gain. For the experimental class average score of N-Gain is 0.62 while the control class 0.51.Then, based on test results influence (simple linear regression) between the activity of students with mathematical reasoning skills gained sig. 0,000 = 0%. Significance level $\alpha = 0.05 = 5\%$. Because Sig.0,00 <0.05 hence H0 is rejected or, in other words H1 accepted. This suggests the hypothesis proposed by the author proved, that there is the influence of problem-based learning to students' mathematical reasoning abilities on subab "Exponent, The Roots and Logarithms" in class X-3 SMA Negeri 1 Jalaksana Brass. Then the R-square values obtained or R2 = 0.817 = 81.70%. These values indicate that the problem-based learning affects students' mathematical reasoning abilities on the subject of "Exponent, The Roots and Logarithms" As much as 81.70%.
2. Based on the analyze of observational data activity of teachers and students in the implementation of problem-based learning that is applied to the experimental class turns out there is increased activity of teachers and students from the first meeting until the fifth meeting. The average value in every meeting the teacher activity reached 83.2% with good criteria and the average value in every meeting of student activity is 78% with good criterion. At the first meeting of teachers and students are still not used in carrying out the problem-based learning. But at the next meeting of teachers and students have started to understand how the problem-based learning is applied. There is an increased capability of information obtained KKM, when the pretest none of the students who reached the KKM, increased during the posttest students who achieve KKM as many as 24 students. This is because each of their meetings learning, researchers gave exercises in the form of worksheets that settlement of the matter menggarahkan on the characteristics of problem-based learning, as this is routinely done at each meeting so that the students get used to solve problems with the steps of problem-based learning. So as to solve the problems students can do so easily and can increase the yield of each holding of the test. It can be concluded that by using values-based learning can be achieved KKM.

B. *Recommendation*

Researchers only apply problem-based learning in class X SMA Negeri 1 Jalaksana Brass and limited to the subject of "Exponent, The Roots and Logarithms", to the researchers expect the results of this study as consideration for teachers and prospective teachers, so that research can be continued research on the subject of different topics.To foster reasoning abilities in mathematics, especially material related to non-routine matters, teachers are advised to use a problem-based learning to encourage students to be more active to build knowledge and develop mathematical reasoning skills.

Developing Reasoning Ability and Curiosity of Students toward Mathematics through Problem Based-Learning

Bukhori[1], Heri Retnawati[2]
[1] Departement of Mathematics Education,Graduate School of Yogyakarta State University, Indonesia
[2] Faculty of Mathematics and Natural Sciences, Yogyakarta State University, Indonesia
bukhori633@gmail.com

Abstract— Learning mathematics is implemented in schools one of which aims to make the students have the ability to use reasoning and an attitude of curiosity in learning mathematics. Therefore, to be accustomed to using his reasoning, then students should be trained to be able to: (1) find pattern on a mathematical phenomenon; (2) formulate mathematical conjecture; and (3) draw conclusions based on valid arguments. Meanwhile, to increase the curiosity, the students need to be trained to get used to: (1) enthusiastic to learn; (2) trying to understand concepts; (3) happy and studious; (4) trying to find a solution difficulty in understanding the lessons; and (5) use the concept that has been studied previously in understanding new concepts. The ability and the attitude can be trained and improved through learning mathematics in the classroom. One approach to learning that are considered effective for improving reasoning ability and attitude of curiosity of students is a problem based-learning (PBL), because in the PBL the issues presented at the beginning of learning is a real problem or it could also be ill-structured so that learning step the next requires investigation of activities of individual or group that requires them to train mathematical reasoning abilities and stimulate curiosity in learning mathematics. The phases of the PBL approach include: (1) to orient students on the issue; (2) organize the students to learn; (3) guiding the investigation; (4) develop and present work; and (5) analyze and evaluate the problem-solving process.

Keywords: *curiosity, mathematical reasoning, problem based-learning*

I. INTRODUCTION

Permendiknas No. 22 of 2006 on the Content Standards states that the objective of mathematics courses in Indonesia, one of which is that the students have the ability to use reasoning and have respect for the usefulness of mathematics in the life of one of them an attitude of curiosity in learning mathematics. In addition, the learning characteristics that arise during the process of teaching and learning in schools in line with Permendikbud 68 in 2013 such that the learning patterns let a student-centered, interactive learning, students actively construct knowledge-based group, sera shades of active learning and critical , Thus, the proper learning of mathematics is based on competency so that one type of skills required to refer to the higher order thinking skills (HOTS).

Meanwhile, math teacher attention to HOTS students in Indonesia is still low. It is one of them can be seen from mathematical reasoning skills students are generally still low. The fact is, the data shown from the results of a survey conducted by TIMSS (Trends International Mathematics and Science Study) in 2011. Following the survey data in mathematics in terms of three aspects, namely: knowledge, application and reasoning as in Table 1 below (Mullis, Martin, Foy, and Arora, 2011: 150).

TABLE 1. AVERAGE SCORES INDONESIA IN 2011 BASED ON DATA TIMSS

Ordinal	Category of Capability	The Average Score	The Maximum Score	The Minimum Score
38	*Knowing*	378	616	331
	Applying	384	617	316
	Reasoning	388	612	322

Source: TIMSS 2011 Data

Survey data above show that the mathematical reasoning abilities of students in Indonesia is still low, so that Indonesia was ranked 38 out of 45 countries are included. This is due to the value of the average scores obtained by students in Indonesia are below average international score which is below a score of 500.

One approach for effective learning to improve reasoning skills and attitudes curiosity of students is a problem-based-learning (PBL). (Fogarty, 1997) stated that the problem based learning curriculum designed a model using real-life contexts problem. Characteristics of learning can be a problem unstructured, open-ended, or issues that are ambiguous. Moreover, PBL is also one of the recommended approach in the learning of mathematics in the curriculum of 2013. Later, in practice PBL needs to be supported by the existence of the learning device. Importance of learning tools is also stated by Posamentier (2007: 47), who said that although many theories suggest about the best way to teach math to students, so it is generally accepted that learning plans are well designed are the main ingredients of successful learning.

Furthermore fact the field regarding the implementation of the curriculum in 2013 found several barriers for teachers, including teachers difficulty arranging time on lesson plans, planning lessons, planning, the assessment, and the sort of knowledge and skill in the preparation of assessment instruments and time constraints in the implementation of learning, the difficulties associated with the device learning, and difficulty activating students (Heri Retnawati, 2015). In addition, there are other findings about the difficulties of teachers in the implementation of teacher assessment is not yet fully understood. difficulties teachers are also found in: developing instruments attitude, implement authentic assessment, formulate indicators, designing rubrics for skills assessment, and collect the scores of several measurement techniques. In addition, teachers can not find a decent application to describe student achievement (Heri Retnawati, 2016: 390) .Therefore, the corresponding mathematical learning device 2013. The demands of the curriculum need to be developed, especially in this study by using the PBL approach.

II. DISCUSSION

A. *Mathematics Learning*

During the learning process, the thought of giving information and then manage and refine the concept before. Learning does not only include the process of receiving new information, ideas and skills, but the new material is the result of reconstruction or synthesis returned by the mind (Joyce & Weil, 2004: 13). In other words, learning is a process of change of behavior, habits, knowledge, attitude, and the ability of a person towards a better direction. These changes resulted from a series of experiences that involve interaction with the environment and the necessary infrastructure. It shows that the environment and various facilities that support has a very important role in the learning process.

As for the scope of school mathematics, Ebbut and Straker (Marsigit, 2009: 8) defines it as follows: (1) mathematics as search activity patterns and relationships, (2) mathematics as creativity requires imagination, intuition and invention, (3) mathematics as problem solving activities (problem solving), (4) mathematics as a tool to communicate.

B. *Problem Based-Learning (PBL)*

PBL is an approach to learning that is initiated by the filing of the issues or questions that are expected to be completed by the student. PBL uses the context of real-world problems to identify students in identifying researching concepts and principles as well as knowing how the solution through the issue (Duch, Groch, & Allen, 2001: 6). In addition, sometimes the problem situations that arise in the learning process is complex and confusing students that need to be studied to examine linkages with different disciplines, in other words the issue in early learning are sometimes ill-structured or open-ended (Fogarty, 1997). Further characteristics of PBL delivered Arends & Kilcher (2010: 326) includes: (1) problems or issues (learning begins with the filing of the problems in students); (2) authentic (students seeking a realistic settlement to a real problem); (3) investigation and problem solving (students actively involved through a series of investigative activities and problem-solving groups); (4) view interdisciplinary linkages (students explore the standpoint of several disciplines when analyzing the problems in the investigation); and (5) a small group collaboration (learning occurs in the context of a small, in a group consisting of five or six students); and (6) the results of discussions and presentations (students demonstrate learning outcomes by creating products and flaunt it. In many cases, the students present the group's work to her friends or other groups).

With PBL, the focus of mobile learning content or material to the issues such as the following illustration.

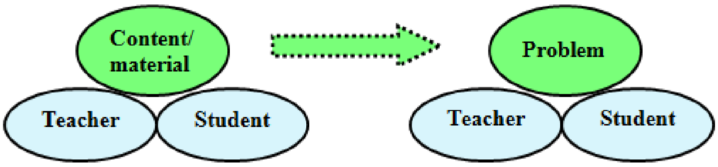

FIGURE 1. FOCUS OF PBL

With the picture above scheme, learning becomes more realistic to create learning that emphasizes real-world, high-level thinking skills, cross-disciplinary learning, independent study, group work skills and communicate through the atmosphere PBL.

TABLE 2. PHASES OF PBL

Phases Of Learnin	Learning Activities
Phase 1: Orient students on issues	The teacher presents real problems through pictures, video and motivate students to perform troubleshooting. Students at this stage make observations on the issues presented.
Phase 2: Organize students to learn	Students in small groups to design steps to resolve problems by collecting information needed by the observations that have been made. Teachers guide students prepare questions and plan for settlement of the issue through the guide in the form of an activity sheet. Students prepare questions to the problems observed.
Phase 3: Guiding investigations of individuals or groups	Students with the group gathered information to conduct an investigation into the problems presented through data or information that has been collected. The data collected is processed to determine the settlement of the problem through investigation. Teachers guide the students carry out the settlement to get a solution to the problem.
Phase 4: Develop and present work	Students communicate the results of the solution to the problems that have been obtained at the front of the classroom or in the other group.
Phase 5: Analyze and evaluate the problem solving process	Students perform evaluation or review of the results that have been obtained. At this stage, teachers guide students in making a final conclusion.

C. *Mathematical Reasoning Ability*

Reasoning ability is one of the important ability to have. Reasoning can be expressed as the science regarding the procedure of withdrawal conclusion (Leighton in Goldstein, 2008: 435). A more complete definition of the reasoning states that the reasoning could be viewed as a cognitive process in which people start with a number of inter-related information further draw conclusions from the information link (Kurtz et al. In Goldstein, 2008: 435). The two statements in line with the suggestion that reasoning is a thought process or activity that seeks the connection between the facts that are known (premise) leads to a new statement or conclusion (Sadiq, 2009: 9).

The process of reasoning to support understanding in mathematics learning and enables students to understand that they learned. This process involves the phenomenon explore, develop ideas, create duagaan mathematics, and the results justify. During the learning process the teacher to help and provide support to students to find the concepts they are learning through exploration. Thus, students can easily understand the mathematical concepts they are learning.

Thus, the opinion of some of the above it is operationally mathematical reasoning referred to in this research include the ability to create a mathematical conjecture, found a pattern on a mathematical phenomenon, draw conclusions from a statement, and provide an alternative for an argument. In other words, the indicators of the ability of mathematical reasoning in this study, are presented in Table 3 below.

TABLE 3. INDICATORS OF MATHEMATICAL REASONING

No.	Indicators Mathematical Reasoning
1.	Finding patterns on a mathematical phenomenon
2.	Formulate a mathematical conjecture
3.	Drawing conclusions from a statement

D. *Curiosity of Students*

Definition of curiosity (curiosity) expressed by many psychologists. (Litman & Spielberger, 2005: 75) defines the attitude of curiosity broadly as a desire to acquire new knowledge and new sensory experiences, which motivate action exploration. In line with this, (Renner, 2006: 305) states that the type of curiosity which is among others include information and new knowledge. A similar opinion illustrates curiosity as an impetus internally to mastery / attainment of knowledge and skills, and it will tend to be reduced in line with the acquisition of knowledge and the results of repetition / exercise (Berlyne, 1954: 180).

Thomas Alva Edison was revealed that the greatest invention in the world one of which is the idea or the ideas of the children and each of the ideas came from a curiosity, so it's important to cultivate curiosity. Moreover, the attitude of curiosity is precisely what has been a lot to contribute in the development of various new discoveries (Stokoe, 2012: 63). Likewise curiosity in learning, critical owned by the students, because with the curiosity would trigger the need for students to learn, investigate or find out. This will lead to an interest to follow up exploration activities or investigation (McElmeel, 2002: 51). In fact, curiosity about something causes a strong desire to understand it.

Curiosity can be increased by connecting the lesson, one of them by hooking sample materials studied to student life (Arends, 2012: 162). By knowing the benefits of use in everyday life, it can bring up to feel the curiosity of students towards learning. Examples workmanship issues contained in problem-based learning (PBL) or in other learning approaches that are realistic. Furthermore, cultivate an attitude of curiosity can be reached in several ways, including: (1) demonstrate things that are unique, new, exciting, shocking or surprising, (2) activities that are challenging students with the knowledge they have (Slavin, 2006: 327).

At a more narrow sense (Kasdhan, at al., 2004: 291) view curiosity as a system of emotional-motivational positively related to exploration activities of the introduction of a thing, the search for the needed information, and setting themselves up for mengekslorasi and get new ideas and opportunity challenges in trying new things. Meanwhile (Ball, 2012: 3) analogize curiosity in science as an impulse that requires understanding of the symptoms that occur in nature.

From the opinions of experts who presented above, it can be concluded that in general curiosity is defined as the desire to obtain more information about the knowledge, skills, or similar natural conditions around new experiences. The desire of curiosity will encourage someone to do a quest for information / knowledge is required. In addition, the finer points of some sense of curiosity outlined above, namely: (1) the desire to obtain some necessary information about an object being studied is the trigger for the attitude of curiosity, (2) the manifestation of the attitude of flavor curious visible from search action / exploration and investigation. The exposure of the aspects and operational indicators curiosity of students that will be used to measure the curiosity of students to mathematics for this study are presented in the table below.

TABLE 4. CURIOSITY ASPECTS AND INDICATORS OF STUDENTS

Aspect	Indicator
Desire to learn	a. Enthusiastic about learning mathematics b. Trying to understand the mathematical concepts c. Happy and diligent study, vigorously, do not get bored with varied tasks.
Investigate	Trying to find a solution difficulty in understanding the math by asking the friends / people who know better, or by reading / studying math book.
Coordinate existing cognitive structure	Using the theory / concept that has been studied previously in understanding new concepts.

E. Development Learning Tool

In planning learning activities, teachers should set up a device that can support the learning process so that it can run properly. The learning tools that will be developed in the study include lesson plan and student activity sheet.

benefits of preparation lesson plan at least serve as a guide to teach or record teachers in the learning process. In addition, the lesson plan will also provide an opportunity for teachers to mentally rehearse prior to the implementation of learning (Posamenteir, at al., 2007: 47). It is very urgent and very beneficial, especially for teachers who are teaching experience is still relatively new to teaching and teachers who try to apply the model / learning approaches that are new.

The use of worksheets students in learning activities greatly help students to cultivate their own ingredients studied or with friends in a form of group discussions. Student worksheet also serves as a learning resource to facilitate learning in groups according to the learning activities developed.

F. Review of Relevan Research

The research is relevant to this study from the aspect of problem based learning to aspects of mathematical reasoning abilities and aspects of the curiosity of students, as follows:

1. Research conducted by Endang Wahyuningsih (2014) in the junior class VIII, entitled "Development of a circle with a learning device problem-based learning approach oriented mathematical reasoning and communication in class VIII SMPN Puring Kebumen". This research resulted in the learning circle with a problem-based approach pemebelajaran oriented mathematical reasoning and communication junior high school students of class VIII. The tests showed that the lesson plan and

worksheets that are developed each valid criteria with very good category. Field trial results showed that the developed lesson plans and worksheets that meet the criteria of a practical and effective. Practicality achieve excellent category based on the evaluation of teachers, both categories based on student responses, and the very good category is based on the observation keterlaksanaan learning. The effectiveness of achieving effective category based mastery learning students. The percentage of the number of students who pass the tests of mathematical reasoning abilities reached 82.82%, the test mathematical communication ability reaches 76.57%, and the learning achievement test reached 79.69%.

2. Research conducted by Mirayanti (2012) on the high school students of class XI in Bima. The study is quasi-experimental research. The population in this study were all high school students in class XI in Bima district in the academic year 2011/2012. Research samples were high school students of class XI each category represent the school well, pretty and less. The study design used is Nonequivalent Control Group Design by using purposive sampling technique. Research results show that there are differences both on the increase in mathematical reasoning ability and the ability of mathematical communication between students who received the study of mathematics by problem-based learning approach and conventional learning at school either category, sufficient and less. In the school category enough, increase the ability of students' mathematical reasoning, either learning using problem-based learning and conventional learning is higher than the category of good schools and less. Improved communication skills students learn mathematical menngunakan problem-based learning in school enough categories, higher than the students in the school category and less good.
3. Research conducted by Tatang Herman at students of SMP Negeri 22 Bandung with a main subject is class VIII B. The title of his research is Problem Based Learning to Enhance Mathematical Reasoning Ability Junior High School Students. This research is the development activities undertaken collaboratively between teachers, students, and faculty by using descriptive qualitative method. The results of these penelitiann visible improvement of mathematical reasoning abilities experienced by students occurs in every cycle. In the first cycle reasoning test results showed the average mean of 7.35 and the second cycle reaches 7.56. Then in the third cycle of learning seem more evolved and is also evidenced by the results of tests of reasoning at the end of the third cycle, which reached an average 7.90.

G. Framework

In the first phase of PBL, students are exposed to the problems that are real that stimulate the curiosity of students. Such problems will raise questions on students, encouraging students reason to hypothesize and speculate. In the process of finding a solution, students need to think logically. Thus, learning by PBL can improve students' mathematical reasoning abilities.

The next phase, students will be guided to plan the inquiry process by forming a group, divide the tasks of investigation, as well as set a specific subtopic-topics to be studied more deeply. So that the investigation can proceed smoothly, the division of tasks for each member of the group must be clear. In this situation, the student will communicate to share role and it is expected to increase their curiosity towards their respective roles in the investigation activities to be undertaken in the next phase.

In the third phase PBL, students are asked to conduct an investigation / discussion groups. At this stage, students can discuss intensively so that they will be asked, answered, criticize, mengevalasi, and to clarify any concepts or mathematical arguments that emerge from the discussions. In this event also allows the development of students' ability to create, refine and explore allegations (conjecture) that solidify their understanding or mathematical concepts being studied, or the mathematical problems are solved. In addition, these activities also allow students to collect and analyze information, conduct investigations, and make conclusions. Thus, the atmosphere of cooperation within the group as described above, can improve communication skills, curiosity and students' mathematical reasoning.

Furthermore, in the fourth phase is the presentation of the work, the students communicate the results of group discussion, either orally or in writing to the teacher and classmates. At this stage, the students rehearsed a lot about how to present their thoughts are kind and courteous to others. Thus, learning by PBL can improve students' mathematical communication skills.

Last phase of the analysis and evaluation of problem-solving process. The core of this activity is to reflect on the thinking of students and the process of investigation or the problem solving process that has been done. Through this phase, various errors will be corrected. Thus, it will improve the ability of mathematical reasoning and mathematics achievement learn some vital lessons.

III. CONCLUSION AND SUGGESTION

PBL is a learning approach that stimulates the power of reason and the attitude of curiosity of students. Moreover, PBL is also a learning approach that is recommended and in accordance with the curriculum of 2013. Each phase in the PBL has a role in enhancing the ability of reasoning and the curiosity of students. Presents problems that will be used in PBL is not easy. The exact problem should include a contextual situation motivate students to complete although not yet know firsthand how that should be done to solve the problem. This does not mean that type of problem to be intractable students, even teachers are expected to predict that siiswa has the potential to solve them. Sometimes PBL can be time consuming long enough if the management class is not managed properly. Therefore, teachers should have a lesson plan carefully, so it is expected to guide and help students exactly how, appropriate and timely.

Teachers as agents of change in the front line of education are expected to implement the PBL approach in teaching mathematics in schools. Thus, it is expected that students have good mathematical reasoning ability and a high curiosity towards mathematics.

ACKNOWLEDGMENT

This paper is part of a research and development tool math learning by problem-based-learning approach to improve mathematical reasoning ability and attitude of curiosity of students. Thanks to Dr. Heri Retnawati on the guidance given in this research and development.

The Development of Module of Learning Quadrilateral Based on Van Hiele Theories

Deshinta P.A.D. Argaswari[1], Budi Usodo[2], Ikrar Pramudya[3]
[1,2,3]Pascasarjana Pendidikan Matematika, Universitas Sebelas Maret
deshintapuspa@yahoo.com

Abstract— The aims of this research are to know the process and to develop a teaching and learning module using Van Hiele theories in learning quadrilateral for grade VII students in middle school. The relevant research state that nowadays students are instantly generalizing the concept of geometry without further understanding about the properties of geometry and the ability of proving and reasoning. Whereas, the purpose of learning geometry is to achieve the deductive thinking which is in level 2 informal deduction based on Van Hiele geometry thinking level. The survey result state that only 10% of students reached level 2 informal deduction, 56,6% students reached level 1 analysis and the rest of students are still in level 0 visualization. The book of reference for learning quadrilateral or module of learning is not written to reach level 2. The book is only consist of definition and properties of quadrilateral without further learning experience for increasing deductive thinking skill. In order to solve this problem, this research develops a module which is written based on phase of learning geometry. The purpose is to make students think and learn quadrilateral in higher geometry thinking level. The quality of this module is assessed based on contains, appearances, graphics, and language. The method of research is research and development with modification of Borg and Gall and Plump method. The module is verified through trial test in a class of students grade VII in order to get data of validity, effectivity, and practically. The result of this research is a module which is consist of two sections. Section one consist of activities in order to increase level 0 to level 1. Section two consist of activities in order to increase level 1 to level 2. Each section is designed as five phase of learning geometry by Van Hiele.

Keywords: Van Hiele, Quadrilateral, Research and Development, Modul of Learning

I. BACKGROUND

Even though learning geometry seems easy because it studies about shapes which is not too abstract, but students face difficulties and has a misconception about geometry (NCTM in Biber, 2013)[1]. Fujita & Jones (2007)[8] indicate that students face difficulties because they do not have enough understanding about the concepts so they overgeneralize the concepts. For example, in learning quadrilateral, mostly student memorize the properties rather than understanding the concept and link the implication of each quadrilateral's definition (Okazaki & Fujita, 2007[12]). This condition shows that students have not reach the goal of learning geometry which is having skills in reasoning and proving through deduction thinking process (Clements & Battista, 1992[3]).

Based on Van Hiele level of thinking geometry, students in junior high schools can be divided into three level of thinking: Level 0 Visualization, Level 1 Analysis, and Level 2 Informal Deduction (Crowley, 1987[5]). Pre-survey is done at grade 7 students at SMP N 1 Selogiri. The results show that only 10% students reach level 2 Informal Deduction, 56 % students reach level 1 Analysis, and the rest of students stay at level 0 Visualization. Students face difficulties in classification of quadrilateral which is the indicator of reaching level 2 informal deduction. Based on direct interview when students doing the survey, students face difficulties to relate each quadrilateral because previously they learn class of quadrilateral separately.

In theories of Van Hiele geometry thinking level, the level of geometry thinking can be increased using instruction. The instruction is given based on Five Phase of Learning Geometry (Erez & Yerushalmy, 2006[7]). This phase of learning is designed to help teacher design a teaching and learning activities in order to increase students' thinking. In this case, this phase can be designed to help all students reach level 1 Analysis. After that, this phase also can be done to help students reach level 2 Informal Deduction. Other than the design of activities, this phase of learning needs teacher's intervention in facilitating the learning activities. It is happened because the increasing of level of thinking cannot be done naturally, meaning that teaching and learning geometry need to be done using activities designed based on five phase of learning geometry and teacher facilitation (Burger, 1986[2]).

This 5 phase of learning geometry is arranged systematically as inquiry phase, free orientation phase, explication phase, direct orientation, and integration phase. The teaching and learning activities is arranged based on these phase and should be arranged systematically. In other hand, students' ability of learning is variety. It means that the speed of learning will be different. Therefore, these phase of learning need to be written in module, so students are able to study individually based on their level of thinking (Daryanto, 2002[6]). In fact, module which contain this phase of level is hard to find in Indonesia. Pre-survey shows that commonly the quadrilateral topic is written with order such as definition of quadrilateral, properties of quadrilateral, area and perimeter of quadrilateral, and evaluation. Teacher also follow the order written in book of reference. Commonly, the book of reference does not provide activities to facilitate students to think deductively.

In order to solve problems of limitation book which provide the five phase of learning geometry and urgency of increasing students' geometry thinking level. This research develops a module of learning quadrilateral based on five phase of learning geometry in order to increase the students' geometry thinking level.

Hence, the research question for this research is how is the process and result of development of a module of learning quadrilateral based on Van Hiele theories which is valid? The purpose of this research are to explain the process of develop and produce a valid module of learning quadrilateral based on Van Hiele theories.

II. LITERATURE REVIEW

Van Hiele model in geometry consist of exist of level, properties of level, and movement from one to another level. Exist of level consist of geometry thinking level of a students. It is consist of five level (Burger, 1986).

1) *Level 0 is called visualization level.* Students in this level are able to give name for selected quadrilateral but they are not able to give correct reason. They likely say "because it looks a like". Students also able to draw a quadrilateral based on its name. The drawing is not detil means there is no sign of similar sides or angles or others.

2) *Level 1 is called analysis level.* Students in this level are able to link the figure of quadrilateral with its properties. They are able to state the properties or analyze quadrilateral based on properties given. But, students in this level could not show the relationship of quadrilateral.

3) *Level 2 is called Informal Deduction level.* Students in this level are able to show how one class of quadrilateral has relation to others class of quadrilateral. Students are able to give reason based on properties of quadrilateral. But, students could not give a reason formally and systematically as proofing.

4) *Level 3 is called Deduction level.* Students in this level are able to proof the geometry statement using postulate, axioma, and proof systematically. This level of thinking is commonly shown by college students or university students.

5) *Level 4 is called rigor level.* Person in this level are expert in proofing deductively the axioma, prostulate in geometry. They are able to work on both Euclidean and Non-euclidean geometry.

Since, students in secondary level is asked to have ability in reasoning, so the level of thinking of students in sedondary is vary from level 0 to level 2. In properties of level is shown that each level is fix, meaning that students cannot naturally jump from one to another level. In order to move from one to another level, teh teaching and learning geometry should be consist of The Five Phase of Learning Geometry (Burger 1986, Clements & Battista, 1992).

1) *Inquiry.* This phase is consist of the activity in order to build students' attention towards the field of study that will be taught. Commonly, the activity of this phase is introducing the field of study or the application of the study.

2) *Free Orientation.* This phase will give experience for students to directly involve in knowing the field study that being taught. The activity of this phase are commonly design as grouping a figures, draw a figures, and others.

3) *Explicitation.* In this phase, students are ask to state their understanding towards the field study that being taught. Students experience how to link their prior knowledge to the new knowledge they got. Activity in this level is commonly design as identify properties of figures.

4) *Direct Orientation.* In this phase students get more complex problems in order to apply students' new knowledge.

5) Integration. This phase is designed to summarize all of knowledge that students learnt during the lesson. Activity of this phase is design as making summary of the lesson or making mind mapping of classification of the field study,

III. METHODS

The subject of the test of this research is students of SMP N 1 Selogiri. Subjects are randomly chosen from grade 7. Validator are purposively chosen from mathematics expert, mathematics practitioner, lecturer, and teacher.

This research use research and development method. Research and development method is a method of research which is used to produce a specific product whether software or hardware (Sugiyono, 2012[14]). This research modify the Plomp and Borg & Gall (in Sukmadinata, 2007[15]) model of research and development. The following are research procedure of this research: 1) Initial Investigation: In this stage, researcher do a literature review about Van Hiele theories, analyze students' level of thinking geometry, and analyze the book of reference which is used by students and teacher. 2) Design: In this stage, the plan of module is designed based on literature review result and analysis result from initial investigation. 3) Realization: In this stage, the researcher make realization of module based on theories and analysis into draft 1 module of learning quadrilateral. The systematic of writting module refer to Daryanto (2002). 4) Test, Evaluation, and Revision: In this stage, the draft 1 module is reviewed by validator of media experts and concept experts.

This research need a data of assessment result towards module which is coming from validator in education experts, mathematics experts, and practitioner and students' comments after using this module as learning media. The data contains a content validation of module of learning.

The research instrument of this research is a validation sheet and students' comments. Students' comments is used to collect data of students's comments towards module. Validation sheet is designed as validator reference in assessing the module of learning quadrilateral based on Van Hiele theories. The components in assessing module are consist of (BNSP, 2007[16]) as: 1) Content aspect: Content aspect consist of validity for compatiblity of competence standard, accurate of contents, up to date of contents, compatibility of Van Hiele theories, compatiility of module's components, and effort of increasing geometry thinking level. 2) Presentation aspect: Presentation aspect contains of presentation technique, presentation of learning, and completeness of presentation based on module's components. 3) Language aspect: Language aspect contains of compatibility of students' development mental level, compatibility with Bahasa Indonesia, and systematically of thinking plot. 4) Graphics aspect: Graphics aspect consist of book size, cover design, content design, ilustration, compatibility of paper, compatibility of cover paper.

The data collected is analyzed using content validity analysis. All data coming from validators of content validator and media validity are compared and is analyze in order to do revisions for the module. Data of students' comments is analyze as qualitative data. Data collecting will stop until validator state that the module is valid and ready to use. Revisions are made based on validators' assessment and students' comments.

IV. RESULT

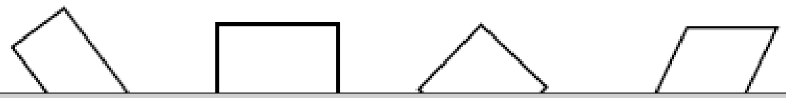
Based on validity contents from validator and students' test, the process and product of this research as follow:

A. Content Validity

Three validator of content expert validate the module based on BNSP's assessment of module. The corrections for module is given as follow:

1) Module 1: This section contains of concept of definition and properties of quadrilateral. In this section, students learn about six class of quadrilateral including paralelogram, rectangle, square, rhombus, kite, and trapezoid. Activity of inquiry phase is designed to give a sufficient information for students about what quadrilateral is. The activity chosen is recognizing the quadrilateral shapes in real life. By recognize the quadrilateral shape in real life, students are expected to build their knowing about classes of quadrilateral that will be material of discussion at class. The revision is given to the instruction because the instruction is not clear and easy to understand. Validator suggest to give instruction one by one to make it easy to be understand. Other than that there is no link to classes of quadrilateral. Activity of free orientation is designed to give opportunities for students to getting involve in knowing the topic discussion. The activity of this phase is grouping quadrilateral into six classes of quadrilateral. Students are expected to be able to grouping the quadrilateral based on its shapes. Revision for this phase is given to the instruction. The instruction is given one by one to make it clear and easy to understand. The revision is made as table 1. Activity of explication phase is designed to encourage students to be able to explain their opinion about topic discussion. The activity of this phase is identify the properties of each class of quadrilateral at section "Tugas". Revision is given to the illustration of the properties in order to help students with visualization level. The instruction of material also revised in order to be easily understand. The revision is made as table 1. Activity of direct orientation is designed to give opportunities for students to work on more complex task. In this phase, the activity is to identify the properties of certain quadrilateral problem. The detail is made as table 1. Activity of integration phase is designed to summarize the topic of discussion. The activity is making a definition for each class of quadrilateral. As addition, given shapes of set of certain quadrilateral in order to help students with visualization level. The detail is made as table 1. As addition for integration phase, the module provide a summary of the properties of quadrilateral. Validators suggest to add more accurate properties and accurate definition of quadrilateral. Other than that, validators suggest to add shapes with specific mark to help students in visualization level.

TABEL 1. ACTIVITY OF MODUL 1

<table>
<tr><th>Phase</th><th>Activity</th></tr>
<tr><td>Free Orientation</td><td>
KEGIATAN 1.1: MENGELOMPOKKAN SEGIEMPAT
Pada kegiatan sebelumnya, kamu menemukan beberapa jenis segiempat yaitu persegi panjang, persegi, jajargenjang, belah ketupat, layang-layang, dan trapesium.
Pada kegiatan dibawah ini kamu akan mengelompokkan keenam jenis bangun segiempat. Ikutilah petunjuk berikut!
1. Potonglah bangun-bangun segiempat dibawah ini.
2. Kelompokkan menjadi 6 jenis segiempat.
3. Tempelkan pada Tabel 3, serta beri nama jenis segiempatnya.


</td></tr>
<tr><td>Explicitation</td><td>
TUGAS 1.1 : Identifikasi sifat-sifat persegi panjang dengan tabel berikut ini!
Tabel 5. Sifat-sifat Persegi Panjang
<table>
<tr><th>Gambar</th><th>Sifat</th><th>(coret pernyataan yang salah)</th></tr>
<tr><td></td><td>Panjang sisi yang berhadapan.</td><td>Sama/tidak sama panjang.</td></tr>
<tr><td></td><td>Kedudukan sisi yang berdekatan.</td><td>Sejajar/berpotongan tegak lurus/ berpotongan tidak tegak lurus.</td></tr>
</table>
</td></tr>
</table>

Direct Orientation	**SOAL 1.1 : Jawablah pertanyaan berikut!**  Gambar di samping adalah persegi panjang PQRS. 1. Sebutkan panjang dua pasang sisi persegi panjang PQRS yang sama panjang!
Integration	**DISKUSI 1.3 : Jawablah pertanyaan-pertanyaan diskusi berikut!**  1. "Jajargenjang adalah segiempat yang panjang sisi berhadapannya sama". Apakah pernyataan di atas cukup untuk menggambarkan jajargenjang? Jelaskan!

2) Module 2: Learning activity 2 contains a discussion about classificatin of quadrilateral. Through this activity, students are expected to reach level 2 informal deduction thinking level. Activity of inquiry phase is knowing about changes of sides or angles which imply a class of quadrilateral become another class of quadrilateral. Students are expected to aware about the relationship of each quadrilateral which is the topic discussion of this section. Validators suggest a revision to the instruction Activity of free orientation phase is experiment of changing sides or angles. Students are expected to experience the changing of sides or angle so they recognized the relationship. The detail is made as table 2. Activity of explication phase is making a Venn diagram of relationship of quadrilateral. Students are expected to show their opinion of quadrilateral relationship that has been discussed. Validators suggest to put a picture of the Venn diagram in order to make student easily understand the instruction. The revision is made as table 2. Activity of direct orientation is answering more complex problem about relationship of quadrilateral. Validators suggest to revise the instruction. The revision is made as table 2. Activity of integration is classify the quadrilateral. Students are expected to use all their knowledge about topic discussion to summarize the classification of quadrilateral. The activity is made as table 2.

TABEL 2. ACTIVITY OF MODUL 2

Phase	Activity

Free Orientation	**Eksperimen** **Lakukan eksperimen pada bangun segiempat dengan mengubah ukuran sisi atau sudutnya.** **Ikutilah petunjuk berikut!** 1. Buatlah **sebuah segiempat** (pilih persegi panjang, jajargenjang, atau belah ketupat)!
Explicitation	**TUGAS 2.1** **Buatlah diagram Venn yang menggambarkan hubungan antara himpunan bangun persegi panjang, persegi, jajargenjang, dan belah ketupat!** Direct Orientation	2. **Misteri Gambar Segiempat.** Sebuah segiempat diambil dari sebuah amplop secara perlahan-lahan seperti gambar berikut. Gambar diambil dengan cara menarik atau merotasi bangun segiempat. Tebaklah kemungkinan gambar yang akan muncul! a.  Gambar 2.7 Kemungkinan bangun apa yang akan muncul? ________
Integration	**DISKUSI 2.1: Berdasarkan Diagram Venn pada Tugas 2.1, jawablah pertanyaan berikut!** (Sumber: Fuys, David., Geddes., & Tischler, Rosamond. 1988. The Van Hiele Model of Thinking in Geometry Am Adolescents) 1. Apakah persegi merupakan anggota kelompok persegi panjang?________________ Mengapa?____ 2. Apakah persegi panjang merupakan anggota kelompok kelompok persegi?________ Mengapa?____

B. *Media Validity*

1) *Cover:* Cover is designed to illustrate the topic discussed in the module. Validators suggest to make a specific illustration according to the classification of quadrilateral. The illustration must contain the classification of quadrilateral because that is the uniqueness of this module. Revision is made as figure 1.

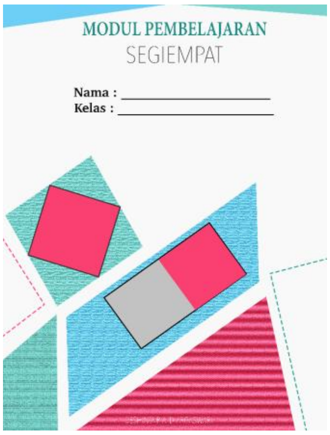

FIGURE 1. MODULE COVER

2) Clipart: Cliparts is used to gain students attention to the module. Validator suggest to use a pictures of application of quadrilateral in real life rather than using clipart. It is used to gain more attention and avoid students' boredom. The revision is made as tabel 3.

TABEL 3.CLIPART

Section	Picture
Clipart before revision	
Clipart after revision	 

C. Students' Test

The module is tested to 11 subjects coming from grade 7 students using random sampling. The purpose of this test is to see how well this module help students to learn quadrilateral. Some revision is made due to students' comments after using the module as learning media. All of students agree that the module help students to learn quadrilateral. For module 1, 63,6 % of students like to work on quadrilateral introduction on inquiry phase, 18,1 % students likes identification of quadrilateral's properties, 9,09 % students like matching pair, and 9,09% students like others. Students who like quadrilateral intoduction state that they like this activity because they enjoy to grouping the quadrilateral and they are able to directly learn how to distinguish the quadrilateral into six groups of quadrilateral. Students who like identify the quadrilateral's property state that they like this activity because they are able to understand easily the properties of quadrilateral.

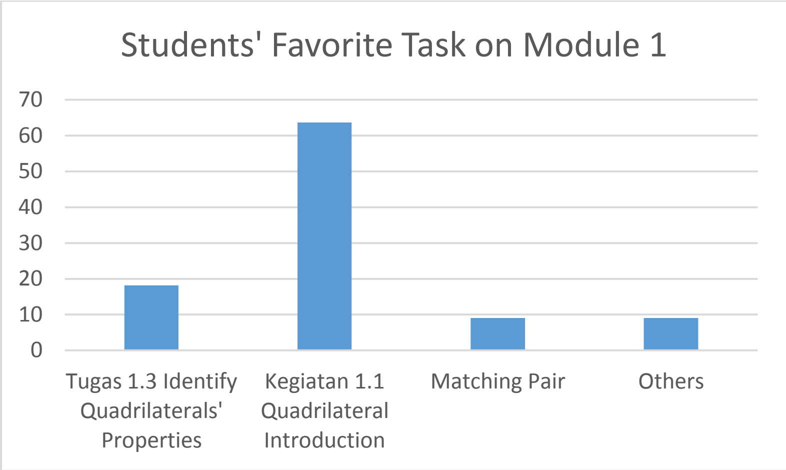

FIGURE 2. STUDENTS' FAVORITE TASK ON MODULE 1

For module 2, 45,5 % students like to work on experiment task, 18,2 % students like Venn Diagram, 18,2 % students like Soal 2.1, and 18,2% students like others. Students who like experiment task state that they like this activity because they learn something new about quadrilateral. They just know that there are relationship of quadrilateral by changing the angles or the sides. Venn Diagram also being liked by students because students can easily understand the relationship of quadrilateral. Soal 2.1 is impressed students as students state that it was fun answering the problem.

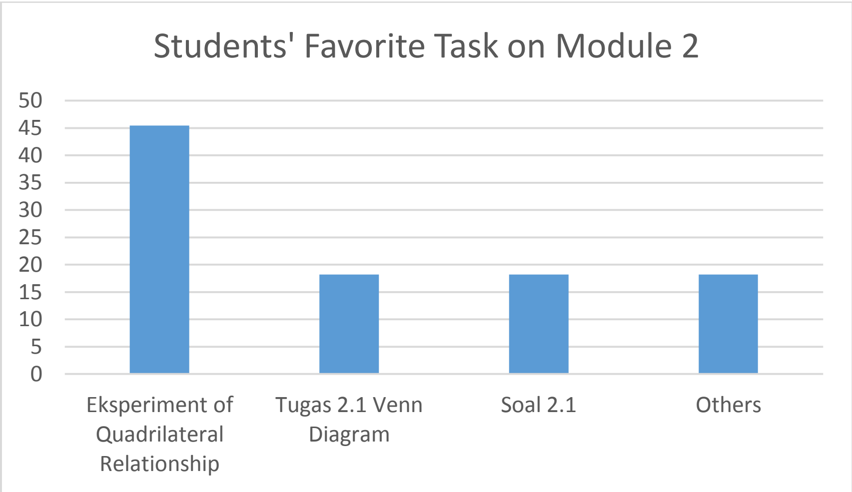

FIGURE 3. STUDENTS' FAVORITE TASK ON MODULE 2

Students face some difficulties to work on module. 9,09% students difficult to work on "Diskusi" where students are ask to summarize the minimum properties of quadrilateral. 18,2 % students face difficulties to understand the definition of parallelogram.

V. DISCUSSION

Through this result, it shows how to implement The Five Phase of Learning Geometry by Van Hiele step by step. For Module 1 which contain of the definition and properties of quadrilateral, the inquiry phase supposed to stimulus students to know the application of quadrilateral in the real life. As addition to gain students interest, module should use the variety of picture of application of quadrilateral. Free orientation phase can be given by grouping the quadrilateral because it helps students to distinguish the classes of quadrilateral. 63,6% students like to work on this activity because students experience by them self how to distinguish the quadrilateral and it is easy to use by the students in visualization level. Because it is the beginning of module, module should be able to help students in the lowest level. Explicitation phase can be given by identify the quadrilateral properties. Based on test result, it can be seen that the format of picture and table of this activity helps students easily understand the properties of each quadrilateral. But students face difficulties on parallelogram topic. It is happened because the definition used in this module is different from the previous one. Naturally, students get confused at the first time, but then by using this definition in the following activity, students can build their undertanding deeply about parallelogram. The direct orientation phase is given by working on complex problem. Last, integration phase can be given by discussion of the minimum properties. 9,09% students state that this activity is quite difficult for them because they need to understand the minimum properties. The next revision of module 1 is given to integration phase consider to the level of difficulties for students.

For module 2 which contains of the relationship of quadrilateral, the inquiry phase is given by build the students' awareness of the relationship of quadrilateral. After that, the free orientation phase is given by experiment to make specific quadrilateral become another class of quadrilateral. Students show enthusiasm in this activity by giving positive comments because they learn something new about quadrilateral. This activity success to give students an experience by themselves in proving the relationship of quadrilateral. The next phase is given by asking students to make a Venn Diagram of the relationship of quadrilateral. Students give positive comments because they feel easily understand the relationship through Venn Diagram. The direct orientation phase is given by working on problems. Mostly problems are posted to gain students' ability in reasoning. On problem quadrilateral mystery, students state that it was fun to guess the quadrilateral. Last, the integration phase is given by asking the relationship. In this phase, students are ask to proving and reasoning by the definition and properties of quadrilateral.

VI. SUMMARY

The process of making the module is summarize as: 1) Review Van Hiele theories especially The Five Phase of Learning and review the topic quadrilateral, 2) Design the activities and questions, 3) Write the draft 1 Module, 4) Test to students and test to validators, 5) Revise based on validators and students' feedback. The module is assessed based on its contents validity of validators. The valid module consist of activities based on the five phase of learning geometry. The valid module consist of: 1) Be familiar with quadrilateral in real life as inquiry phase, 2) Grouping quadrilateral as free orientation phase, 3) Identify quadrilateral's properties as explicitation phase, 4) Solving problem as direct orientation phase, and 5) Summarize the definition of quadrilateral as integration phase. The suggestion for futher research is to consider the integration phase. Some students face difficulties when they need to express their ideas in writting. The module design might included an activity as pre-activity before activity which ask students to write their ideas or opinion.

Acknowledgment

We would like to thank Dr. Mardiyana who kindly become validator for validation sheets. We also would like to thank Desyarti Safarini S.Pd, M.Si, Dhitta Puti Sarasvati, M.Ed, Budi Huang, Sutopo S.Pd, M.Pd, Agus Kristanto, Supriyadi Wibowo S.Si, M.Si, who kindly become our validator and give suggestion for module revision. We would like to thank Tulus Sarnyoto, S.Pd, and Tri Murniati, S.Pd, who kindly support the realization of this research and kindly help us connect to students. Finally, we would like to thank SMP N 1 Selogiri, Universitas Sebelas Maret, and Sampoerna University, who support us doing this research and development.

The Role of Productive Struggle to Enhance Learning Mathematics with Understanding

Dian Permatasari, S.Pd[1]
[1]PPs Universitas Negeri Yogyakarta
dian.permatasari750@gmail.com

Abstract— Struggle is a natural part of the learning process that refers to a student's intellectual effort to expand their understanding of the mathematical concepts that challenge but fall because of student's capabilities. This paper discuss about the classification of student's struggle and the teacher responses, the role of productive struggle in learning mathematics with understanding, and strategies to supporting productive struggle. Productive struggles are identified as an important component of effective mathematics teaching and learning, implying that good teaching involves placing students in problem solving situations where they would have difficulty and frustration experience that could serve as a learning opportunity. Student's effort to learn mathematics, figure something out that is not immediately obvious can help students in their thoughts and play an important role in deepening the student's understanding. Teachers can give appropriate guidance and support to maintain the mathematics understanding and opportunities to think more deeply about mathematical concepts. When students struggle, there are consequences of "incorrect" answers. It is not seen as failures but rather opportunities to explore, grow, and learn serve better support and motivate students to persist. Teaching that uses productive struggle leads to long-term benefits, with students more able to apply their learning to new problem situations. Mathematics teaching using student's struggles can be good opportunities to deepening their understanding of mathematics so that it can be effective. This study suggests the productive role student struggle can play in supporting student learning with understanding.

Keywords: *productive struggle, learning process, deep understanding*

I. INTRODUCTION

Student's struggle in learning mathematics is often seen in a negative light and viewed as a problem or learning difficulty [1]. Sometimes, the cause of it will be attempted to remove by diagnosis and remediation [2]. There is a negative belief that struggling with a mathematical task is not viewed as an opportunity to learn but as a weakness [3]. It would be hard to see that student's struggle in mathematics could be viewed as positive thing and as a learning opportunity.

Recently, National Council of Teachers of Mathematics (NCTM) released policy document, Principles to Actions. It notes that supporting productive struggle in learning mathematics is one of the eight important teaching practices [4]. Struggle refers to student's effort to make sense mathematics, find something out that is not immediately obvious. It is not used to refer needless frustration levels of challenge created by difficult problems [1].

Struggle is essential to intellectual growth has a long history. Dewey referred to the process of engaging students in some confusion or doubt as essential for building deep understanding. In the other hand, Piaget also thinks that student's struggle as a process of restructuring their disequilibrium towards new understanding [2]. Prior study by Hiebert and Grouws suggest that struggle is a necessary component of learning mathematics with understanding [1]. Warshauer also suggests that productive struggle can support doing mathematics and its implications on student learning with understanding [2]. Teachers and instructional designers also can integrate student struggle into tasks and instructional practices rather than avoid or prevent it. Productive struggles are identified as an important component of effective mathematics teaching and learning, implying that good teaching involves placing students in problem solving situations where they would have difficulty and frustration experience that could serve as a learning opportunity [5]. This paper tries to discuss about the role of productive struggle to enhance learning mathematics with understanding.

II. Discussion

A. Productive Struggle

Struggle is a natural part of the learning process. It refers to that a student's intellectual effort to expand their understanding of the mathematical concepts that challenge but fall because of student's capabilities [1]. Student's struggle is an opportunity for investigating more deeply into understanding the mathematical problems and the relationships among mathematical ideas, instead of simply seeking correct solutions [4]. Thus, struggle is a student's intellectual effort to expand their understanding of the mathematical concept by investigating more deeply the mathematical problems and *the* relationship among mathematical ideas, instead of simply seeking solution of a challenge problem but they fall because of their capabilities. There are some types of struggle [2][6].

1) *Get started:* Students feel confuse about what the task asked them to do ("I kind of understand it…but I'm a little confused"). Some students may even proclaim they did not remember doing problems of this type though it appeared vaguely familiar to them ("I have absolutely no idea….I don't remember that far"). Then, they call for help ("I need help") and gesture uncertainty and resignation (looks, thinks, sits back and then says, "I don't know") or show no work on their paper.

2) *Carry out a process:* Some students get difficult to carry out the procedure and the demonstrated or voiced some plan for achieving the goal of the task but encountered an impasse. These impasses tended to revolve around an inability to implement a process such as solving the problem.

3) *Uncertainty in explanation and sense making*: Students are uncertainty in explaining or sharing their work in small groups or with the whole class. In order for students to complete each task, they are expected to explain their work and solutions in writing and in many examples to each other or to the class. Students often struggled to verbalize their thinking and give reasons for their strategies even if their answer appears correct.

4) *Express misconception and errors*: Struggle is involved the students' misconceptions appeared to be instances when deep-seated mistaken ideas were used as the basis for solving problems rather than student's confusion or possible error due to carelessness.

Teacher must support student's struggle, so it is become positive endeavor and not full of difficulties and frustration [2]. Teacher needs to be careful to select the best responses of the struggle. Teacher's responses to student's struggle generally divided into four types [2][6].

1) *Telling*: In a telling responses, teachers often provides sufficient information for the students to overcome the struggle, suggest a new approach or strategy, correct an error, evaluate students work, related to simpler problem and decrease process time.

2) *Directed guidance*: Directed guidance involves redirecting student thinking toward the teacher's thinking, narrowed down possibilities for action, directing an action, breaking down the problems into smaller parts or altered problems to an analogous one such as from an algebraic to numerical ones. It is done by asking open-ended questions, breaking down the problem into smaller parts, and narrowing down what the student might try next.

3) *Probing guidance*: Probing guidance puts the struggle back into the student's lap. Teacher offers ideas based on the student's thinking, asks for an explanation that might surface an error, or asks for reasons and justifications. Then, teacher must seek explanation that could get at an error or misconception and ask for written work of student's thinking.

4) *Affordance*: Affordance provides an opportunity for students to continue to engage in thinking about the problem and build on their ideas with little help from the teacher. Teacher is explicit in encouraging students to continue their effort in their task. The characteristics of these types of respond are ask for detailed explanation, build on students thinking, press for justification, sense making with group or individually, and afford time for students to work.

All of these approaches are useful as long as the level of cognitive demand remains high, and student thinking is supported [3]. When students show effort to solving the confusing problems or making sense of challenging ideas, they engage productive struggle process [7]. Productive struggle is fostered through what psychologists have termed desirable difficulties; challenges that compel the learner to repeatedly retrieve information over time, thereby strengthening long-term memory for flexible transfer of the information to new contexts later [7]. Productive struggle, similar with to other executive function like cognitive skills that help the brain organize and act on information, is supported by a developmental progression in thinking and learning [3]. It is a core component of effective mathematics teaching and learning, implying that good teaching involves putting students in problem-solving situations where they will feel the difficulties and frustrations that could serve as learning opportunities [5]. Students can experience productive struggle when given a task slightly beyond their abilities. Some factors influence productive struggle, that is:

1) Mathematical self-image: Mathematical self-image is related student's perception about their mathematical ability. Students often think that mathematical ability is something that some students are skilled at rather that a behavior that everyone can develop [3]. Because of it, motivation is needed. Motivation for productive struggle requires a growth mindset. It is an understanding that success is a result of effort more than of raw ability. It makes students want to new challenges, and enthusiastic rather than be afraid about learning. Students who believe that their ability levels are fixed are less motivated to engage in productive struggle because they afraid of failure, resist the risks, and worry about the judgments of others, thwarting their own learning [7].

2) Student's disposition with challenging mathematical task: Student's disposition depends on whether they (1) find the task interesting, (2) believe that they know enough mathematics to be able to solve it, and (3) believe that solving it is worth the effort. Student's belief that effort is more important than innate ability is the main factor. In order to persevere, one needs to view the struggle that may to be a part of problem solving as an opportunity to learn. Motivation enables a solver to see struggle as a natural part of the learning process, and to see that confronting and working through struggle can ultimately be helpful [5].

3) Support and feedback: Effective feedback makes clear about what the goal is, what progress they are making toward that goal, and what they need to do next to make better progress. The durability of students' motivation to do in struggling to achieve a goal is mediated by the quality of the teacher-student relationship and the scaffolding provided through feedback. Correcting students' errors, effective feedback guides students to develop better strategies for processing and understanding the material so that they get mastery, confidence, and motivation to continue to support effort in productive struggle [6].

Struggle is not productive when students become frustrated because the goal is unclear or far out of reach, they do not feel safe to fail, or they do not receive adequate, appropriate support. Struggle can be destructive, and teachers need to intervene after finding that students are not making any progress and feeling that their efforts are pointless [6]. Struggle is productive if student's can maintain the initial goals and cognitive demand of the task, support their thinking by acknowledging effort and mathematical understanding, and move forward in solving the task through their actions [2].

B. The Role of Productive Struggle in Learning Mathematics with Understanding

Struggle is a necessary component of learning mathematics with understanding [1]. Understanding is defined as the mental connections among mathematical facts, ideas, and procedures, and then struggling is viewed as a process that reconfigures these things [1]. Relationships among facts, ideas, and procedures are reformed when new information cannot easily be assimilated or when the old relationships are found to be inadequate to make sense of a new problem [9].

Understanding is crucial because learning with understanding can be used flexibly, adapted to new situations, and used to learn new things. It is the most useful things to know in a changing and unpredictable world. Students who lack understanding and must resort to memorizing are likely to feel little sense of satisfaction and are likely to withdraw from learning. Understanding gives student confidence and engagement; not understanding leads to disillusionment and disengagement [11].

Understanding is participating in a community of people who are becoming expert at doing and making sense of mathematics, then struggling is vital because it can be an essential aspect of personal meaning making within the community [14]. Understanding is also important because it is one of the most intellectually satisfying experiences, and, on the other hand, not understanding is one of the most frustrating and ultimately defeating experiences. Learning mathematics with understanding has increasingly received attention from mathematics educators and psychologists and has progressively been elevated to one of the most important goals of the mathematical education of all students [10].

Students who are given opportunities to understand, from the beginning, and who work to develop understanding are likely to experience the kind of internal rewards that keep them engaged. Student's effort to learn mathematics, find something out that is not immediately obvious can help students in their thoughts and play an important role in deepening the student's understanding. In summary, struggling with important mathematics is implicated in both definitions of understanding by identifying the common processes hypothesized to develop understanding. Mathematics teaching using student's struggles can be good opportunities to deepening their understanding of mathematics so that it can be effective.

C. Strategies to Supporting Productive Struggle

To support productive learning, students must realize that they have an ability of doing well in mathematics with their effort and perseverance in reasoning, sense making, and problem solving. Teachers provide support and guidance for students, individually and collectively, to work through uncertainties as they struggle with representing a mathematical relationship, explaining and justifying their reasoning, or finding a solution strategy for a mathematical problem. The table below summarizes teacher and student actions supporting struggle as a natural aspect of learning in the mathematics classroom [4].

TABEL 1. SUMMARIZES TEACHER AND STUDENT ACTIONS SUPPORTING STRUGGLE

What are teachers doing?	*What are students doing?*
• Ancipating what students might struggle with during a lesson and being prepared to support them productively through the struggle • Giving students time to struggle with tasks, and asking questions that scaffold student's thinking without stepping in to do the work for them • Helping students realize that confusion and error are a natural part of learning, by facilitating discussions on mistakes, misconceptions, and struggles. • Praising students for their efforts in making sense of mathematical ideas and perseverance in reasoning through problems.	• Struggling at times with mathematics tasks but knowing that breakthroughs often emerge from confusion and struggle. • Asking questions that are related to the sources of the struggle and will help them make progress in understanding and solving tasks. • Persevering in solving problems and realizing that is acceptable to say, "I don't know how to proceed here," but it is not acceptable to give up. • Helping one another without telling their classmates what the answer is or how to solve the problem.

Teacher and student must cooperate to support struggle in mathematics classroom. Teachers need to select tasks carefully that require students to struggle and provide the support that students need without giving students too much help. Students need sufficient time, not only to solve difficult mathematical problems, but also to develop genuine curiosity and durability [3]. They also influence how students perceive and approach struggle in the mathematics classroom. They can give appropriate guidance and support to maintain the mathematics understanding and opportunities to think more deeply about mathematical concepts. In the below, there are some strategy to support student struggle and make it productive [3].

- Set goals at the beginning of the lesson and keep track of student progress during the lesson.
- Set problems in a familiar setting whenever possible, such as a sport or a familiar everyday task.
- Support students by providing appropriate tasks, tools, and representations.
- Group students heterogeneously, which helps struggling students.
- Establish high mathematical expectations (i.e., doing mathematics requires effort).
- Use good questioning techniques, such as asking students to explain how they solved a problem and why a strategy works or ask them to describe another way to solve the same problem.
- Provide time for group reflection during problem-solving activities. This can help students recognize unproductive strategies.
- Compare student outcomes at the end of the lesson to your original goals.

Supporting from teacher, in one side can enhance and in other instances diminish the level of student learning. It depends on the circumstances, including the goals of the task, the student's prior knowledge, and the student's willingness to attempt to do the problem. Teachers can incorporate into their practice explicit reminders to students that struggling to make sense of mathematics is an important and natural part of learning. Rather than avoiding this phenomenon, teachers can integrate struggle as part of doing mathematics by acknowledging students' consternation, encouraging perseverance, asking questions, and offering time to work through problems. Table 3 shows the outlines teaching strategies that remind students of the positive aspects of struggle and student actions that indicate productive engagement [6].

TABEL 2. STRATEGIES AND INDICATIONS OF PRODUCTIVE STRUGGLE

	Teaching Strategies	*Student indicators of a Productive Struggle*
Question	Teacher asks question that help students focus on their thinking and identify the source of their struggle, then encourage students to build on their thinking or look at other ways to approach the problem.	Students ask questions to identify the source of their struggle, write down their ideas, clarify ideas with others, and consider alternative strategies or representations to address their struggle.
Encourage	Teacher encourages students to reflect on their work and support student struggle in their effort and not just in getting the correct answers.	Students use their effort to solve problems and try to make sense of their work, not only satisfied with a correct answer or that they perceive themselves as smart or not.
Give time	Teacher gives time and support for students to manage their struggle through adversity and failure by not stepping in too soon or too much, thereby taking the intellectual work away from the students	Students use their time to develop and follow through on their strategies, evaluate their progress, and understand what they can do and what still remains to be done.
Acknowledge	Teacher acknowledges that struggle is an important part of learning and doing mathematics	Students persist in their work to make sense of and to solve their problem and not give up or get discouraged easily.

When students appear confused, unable to make sense of an answer, or reach an impasse in working on their task [6]. This is not obstacle in learning but it is an opportunity for develop student's understanding of mathematics. When students struggle, there are consequences of "incorrect" answers. It is not seen as failures but rather opportunities to explore, grow, and learn serve better support and motivate students to persist. One of cognitive approach to learning mathematics with understanding is using student's error or incorrect answer as sources of information about their understanding [9]. By incorporating instructional approaches that acknowledge student's struggles and effectively support, guide, and feedback the student's thinking toward a productive resolution, student given opportunities to strengthen their disposition toward challenging tasks and they will persist through their struggle to make sense of and understand important mathematics.

III. CONCLUSION

Struggle is a student's intellectual effort to expand their understanding of the mathematical concept by investigating more deeply the mathematical problems and the relationship among mathematical ideas, instead of simply seeking solution of a challenge problem but they fall because of their capabilities. There are some type of struggles, i.e., get started, carry out a process, uncertainty in explanation and sense making, and express misconception and errors. Teacher's responses to student's struggle generally divided into four types, i.e., telling, directed guidance, probing guidance, and affordance. Struggling to make sense of mathematics is a necessary component of learning mathematics with understanding. Understanding is the mental connections among mathematical facts, ideas, and procedures and learning with understanding can be used flexibly, adapted to new situations, and used to learn new things. Students who are given opportunities to understand, from the beginning, and who work to develop understanding are likely to experience the kind of internal rewards that keep them engaged. Teachers provide support and guidance for students, individually and collectively, to work through uncertainties as they struggle with representing a mathematical relationship, explaining and justifying their reasoning, or finding a solution strategy for a mathematical problem. Teachers can incorporate into their practice explicit reminders to students that struggling to make sense of mathematics is an important and natural part of learning. Rather than avoiding this phenomenon, teachers can integrate struggle as part of doing mathematics by acknowledging students' consternation, encouraging perseverance, asking questions, and offering time to work through problems. Teaching that uses productive struggle leads to long-term benefits, with students more able to apply their learning to new problem situations. Mathematics teaching using student's struggles can be good opportunities to deepening their understanding of mathematics so that it can be effective.

Didactical Design Research of Mathematical Communication about Concept of Cuboid Volume in Elementary School

Hj. Epon Nur'aeni[1], Muhammad Rijal Wahid Muharram[2]
[1,2]UPI Kampus Tasikmalaya
eponalamsyah@yahoo.com

Abstract- The research based on learning obstacle in preliminary research about mathematical communication for concept of cuboid volume which must be understood student. These concepts are taught in the fifth grade. The research purposes to be achieved is of development of learning design of cuboid volume to mathematical communication of student in problem solving story. Learning obstacles are: students haven't able to use mathematical concept to mathematical models, to use mathematical concept to life, and haven't able to use therelationship between mathematical topics in life. To minimize learning obstacles for concept of cuboid volume, then drafted a didactical design. Didactical design organized at SDN Rahayu Kecamatan Mangkubumi, Tasikmalaya as much as 2 (two) cycles, are preliminary didactical design and revised didactical design. Preliminary didactical design implemented to minimize learning obstacle for mathematical communication skills for concept of cuboid volume and revised didactical design to fixing Preliminary didactical design. Didactical Design Research consists of three phases: 1) analysing of didactical situation before learning be in the form of Hypothetic Didactical Design, including ADP; 2) Metapedadidactical Analysis; 3) Restropective analysis between result of hypothetical didactical situation analysis with analysis result of metapedadidactical analysis. This research can increasing mathematical communication understandings and skills for concept of cuboid volume.

Keywords: *Learning obstacle, Didactical Design, Cuboid Volume, Mathematical Communication*

I. INTRODUCTION

Based on article 31 point 1 of The *1945 Constitution* of the Republic of Indonesia "Every citizen has the right to receive education". Curriculum is a educational foundation in school. In Kurikulum Tingkat Satuan Pendidikan (KTSP), mathematics is one of mandatory subjects in every level of education, include elementary school. Mathematics is used in all fields of science as well as having an important part in solving the problems in life. Therefore, mathematical knowledge should be mastered by the students as early as possible. Understanding the concepts of material in the mathematical learning in elementary school is an implicit prerequisite to continue their education to a higher level.

Education aims to humanize humas, make not knowing to knowing, and can't be able to able. Aim to improve the quality of human resources in education, referes to act of the republis of indonesia number 20 year 2003 article 3 "The National Education functions to develop the capability, character, and civilization of the nation for enhancing its intellectual capacity, and is aimed at developing learners'potentials so that they become persons imbued with human value who are faithful and pious to one and only God; who possess morals and noble character; who are healthy, knowledgeable, competent, creative, independent; and as citizens, are democratic and responsible.". In addition, education is also one way of formulation of the human ability to use reason effectively and efficiently as the answer to face with problems that arise in creating a better future. But in reality, education hasn't reached its intended purpose, both in terms of the learning process and the result of the students' achievement, not show satisfactory results.

The problem of education has always been an interesting topic, both among teacher, parents, even among the educational expert. This is something that is fair because everyone wants the best education for students as the iron stock for our nation. One of the problems of education is on math, this is stilll due to low student achievement in that subject. Efforts to improve the quality of mathematics education in Indonesia has long been implemented, but complaints about the difficulty of learning mathematics still continue to be found.

Mathematical learning is identical to drill critical thinking skill of students.Geometry is one of material of mathematics at elementary school. Understand and calculate the cuboid volume is one thing to be achieved student of elementary school in mathemaical learning. Questions about cuboid volume usually presented with picture and the students were only instructed to calculate the cuboid volume. Related to that, the students presented only the usual problems or questions, so that when students faced to the unusual problems, student will have difficulty and will not be drill to have critical thinking.

Based on the condition of cuboid volume learning, the research is aimed to developing of learning design collaborate with a variaty of learning methods, media, and techniques which is relevant. This research expected to improve mathematical learning process, especially on the material of cuboid volume in elementary school. With the development of learning design expected to facilitate students to think critically is every learning, especially mathematics.

Based on the research background, the formulation of the problem in this study is "How to didactical design in computing and understanding the concept of cuboid volume to improve the mathematical communication in students?".

Start from the formulation of problems, then drafted specific research questions as follows:

1. How a learning obstacle experienced by elementary school student in the material of cuboid volume?
2. How the didactical design to resolve of learning obstacle of student in the material of cuboid volume?
3. How implementation of didactical design on student in the material of cuboid volume?

The research purposes to be achieved is "Development of learning design of cuboid volume to mathematical communication of student in story problem solving in grade V of elementary school". While specifically, the research purposes to be achieved are:

1. To know and understand a learning obstacle experienced by elementary school student in the material of cuboid volume?
2. To desribe the didactical design to resolve of learning obstacle of student in the material of cuboid volume?
3. To describe implementation of didactical design on student in the material of cuboid volume?

Benefits of research are: 1) The theoritical benefits and 2) The practical benefits. The theoritical benefits are: expected to contribute positively in the development of the theory of mathematical learning, especially on the material of cuboid volume to improve the quality of education corresponding national education goals. Then, the practical benefits are:

a. For the teacher, as an input to develop innovative learning design in order to achieve optimal learning objectives, and to pre-service teacher as a preparation to face the profession.
b. For the student:
   1) Get a new material about cuboid volume;
   2) Improving the understanding of the concept of cuboid volume;
   3) Drill for critical thinking in the learning process.
c. For reseachers, can obtain direct experience in developing instrument and didactical design of cuboid volume.
d. For schools, contribution of ideas in written form related learning of cuboid volume.

II. RESEARCH METHOD

Sugiyono (2007 , pg.6) suggests that "the research method can be interpreted as a scientific way to get valid data to be found, developed and demonstrated that in turn can be used to understand, solve and anticipate a problem". Method used by researcher on this study is Didactical Design Research.

Didactical design is a learning plan form of teaching materials which aiming to reduce or eliminate learning obstacle based on the preliminary study. So that students being able to understand a concept or operates whole learning materials. The purpose of this didactical design is to reduce and eliminate learning obstacle on student so they are able to understand a concept as a whole.

Didactical Design Research consists of three stages, namely: (1) situation didactical analysis before learning process in the form of a didactical design hypothesis including ADP; (2) Metapedadidactical analysis, and (3) Retrospective analysis which relating the outcome of situation didactical analysis hypothesis and metapedadidactical analysis.

III. RESEARCH FINDINGS

A *cuboid* is a three-dimensional space formed by three pairs of square or rectangular, with at least one pair of which sized differently. A *cuboid* has 6 faces, 12 edges and 8 vertexes. A *cuboid* is formed by six congruent squares called a *cube.*The concept of *cuboid* volumes surely cannot be separated with components of the *cuboid*. Generally in schools, including elementary schools (SD), it involves the length, width, and height of the *cuboid* or better known as *length* x *width* x *height = volume.*

The first step of this DDR based research is organising preliminary study instruments. This instrument contained Competency Standard (SK), Basic Competency (KD), Learning Obstacles, Mathematical Communication Indicator, and Learning Indicator. SK and KD adjusted to School-based Curriculum (KTSP) which cuboid concept is one of them. As for Mathematical Communication Indicator which contained on the preliminary study instrument and the goal of this didactic design are:

a. Students are using the concept/ mathematical language to interpret mathematical idea.
b. Students are able to state the mathematical concept into mathematical model.
c. Students are able to pour the mathematical concept on their daily lives.
d. Students are able to understand the relation among mathematical topics to daily life.

Based in the preliminary study which had done on October 23rd 2015, learning obstacles was found. There three types of learning obstacles found, namely:

a. Type 1: Learning obstacle related to pour mathematical concept into mathematical model;
b. Type 2: Learning obstacle related to pour mathematical concept to the daily life;
c. Type 3: Learning obstacle related to pour mathematical topics to the daily life.

The next step after the obstacles obtained is creating learning didactical design. Learning didactical design was made in order to achieve learning goals. This didactical design, which researcher used, is related to the concept of cuboid volume and was done in 2 cycles (2 meetings) at SDN Rahayu Kecamatan Mangkubumi.

Early didactic design (cycle 1) was done during 2 hour learning time on Saturday, November 7th 2015. Based on the learning indicator and to achieve goal desired, the learning process was also done based on learning steps in lesson plan *(*RPP*)* which directed students to achieve learning goal. Learning process on the first cycle, intended to make students understand the concept of cuboid volume, then students were guided to do the student worksheet (LKS), in which students were doing with the their learning group. The groups were formed using colored paper, which let the students who picked the same color in the same group. After the learning groups formed, the students were given a worksheet consists of 3 activities to do with their group. Each group was guided by researchers while doing the activities. In early didactic learning design (cycle 1), students needed an intense guidance because the problems on the worksheet were not usual problems for them. Moreover, to explain about the concept of cuboidvolume in the first cycle Medias are needed, therefore, researchers used a cube and rectangular prism. With those medias, researchers was hoping the students could understand the concept of cuboidvolume, so the students are able to solve problems related to cuboidvolume. Each learning groups were evaluated after finishing the worksheet.

Since on early didactical design revision is needed, a revised didactical design was created. The revised didactical design was organised based on the implementation in the previous cycle. Based on early didactical design, there were things which need revision, and things which were revised are: The learning process is going to be done individually, the evaluation process is going to be done individually, and the duration is to be prolonged; from 2 x 35 minutes to 2 x 40 minutes and problem alteration.

The revised didactical design (cycle 2) was done on Friday, November 13th 2015 at SDN Rahayu. This revised design was intended to improve learning process which had done on earlier cycle (cycle 1). In this revised design, the difference between the earlier cycle and the second cycle was on the worksheet which done individually. This revised design shown different things compared to the early didactic design, in the revised design, researchers were not providing medias, because researchers believed that the students were already understood the concept of cuboid volume. The students were already understood the concept of cuboidvolume, it was proven as the need of guidance from researchers to students was decreased.

IV. RESEARCH DISCUSSION

Based on preliminary study, it was revealed that there are three types of learning obstacle, namely:

a. Type 1: Learning obstacle related to pour mathematical concept into mathematical model
b. Type 2: Learning obstacle related to pour mathematical concept to the daily life
c. Type 3: Learning obstacle related to pour mathematical topics to the daily life.

All three types of learning obstacle, was revealed from preliminary study which had done before didactical design. To minimize all three types of learning obstacle, then didactical design was done which consists of early didactical design and revised didactical design. to minimize the learning is through LKS obstacle to learning in any didactical design. LKS learning in every didactical design was a method to minimize learning obstacle.

Students learning obstacle could be resolved and minimized by didactical design, it was proven with the increased of students mathematical communication understanding in each meeting, one of characteristic is guidance from researchers to students was decreased and final evaluation of this research was increased from a preliminary study.

Implementation of didactical design at SDN Rahayu Kecamatan Mangkubumi, Tasikmalaya, was done in 2 cycles. There was increased of students mathematical communication concepts of cuboid volume from early didactical design to revised didactical design. Teaching method of early didactical design and revised didactical design were same, which was guidance finding method. However, the guidance from researchers was decreased from early didactical design to revised didactical design because the students were already understood and appliedtheir communication skills in problem solving.

V. CONCLUSION

Based on the result of research and discussion, it can be concluded:

1. Based on preliminary study, it was revealed that there are three types of learning obstacle, namely:
   a. Type 1: Learning obstacle related to pour mathematical concept into mathematical model
   b. Type 2: Learning obstacle related to pour mathematical concept to the daily life
   c. Type 3: Learning obstacle related to pour mathematical topics to the daily life.
2. To minimize all three types of learning obstacle, then didactical design was done which consists of early didactical design and revised didactical design.
   a. Didactical design was done at SDN Rahayu Kecamatan Mangkubumi Kota Tasikmalaya in fifth grade with 25 students.
   b. Students learning obstacle could be resolved and minimized by didactical design, it was proven with the increased of students mathematical communication understanding in each meeting, one of characteristic is guidance from researchers to students was decreased and final evaluation of this research was increased from a preliminary study.

VI. SUGGESTION

Based on the result of research and conclusion, then the researcher have some suggestions, as follows:

1. The didactical design has been drafted is one of the learning design of teaching materials that can be used in each lesson can be developed according to the needs.
2. This research is expected to continue to be develop by drafting the didactical design better about mathematical communication in concept of cuboid volume

e-mail: dwi2purnomo@yahoo.co.id

Abstract-It is an article as the result of a study to analysis happening of mathematical students' metacognition changes in solving and describing the characteristic of mathematical problem. The metacognition is based on the changes of awareness, evaluation, and regulation as the components of it. To make known of them, the writer has determined the indicators of each of the components which are spelled out into descriptors in order the process of metacognition changes can be seen. The process of the study involved 23 Students of Mathematics Department who finished Differential Calculus lesson as the subjects of the study. The subjects of the study were given mathematical problems about the application of function derivation to make known of the maximum area of a field. The data of the study was obtained consists of mathematical problem worksheet, record, metacognition questionnaire, and interview transcript. Then, the data was analysed by using Glaser's and Strauss' constant comparative models. Based on the analyzing, it can be inferred that the characterization of mathematical students' metacognition changes in solving mathematical problems can be classified by three categories: (1) metacognition changing process with complete-order indicator, (2) metacognition changing process with complete-disorder indicator, and (3) metacognition changing process with incomplete indicator. During the happening of the process of metacognition changes, the subject of the study, carried out the activities which are suitable to awareness, evaluation, and regulation indicators determined.

Key Words: *metacognition, awareness, evaluation, regulation, mathematical problem*

I ACKNOWLEDGEMENT

Mathematics owns direct and indirect objects. According to Gagne (Soedjadi, 2000; Hudojo, 2008) direct object consists of fact, concept, operation, and principle. While indirect object consists of logical thinking capability, problem solving, analytical thinking, positive thinking against mathematics, carefulness, perseverance, discipline, and the other cases which will implicitly obtain if someone learn mathematics. One of the objects is concept. The orientation of the concept of mathematics can be done through learning activity. Djamarah (2008) states that someone who owns the concept could carry out the abstraction. So that, he or she is able to translate and invite awareness and form mental representation. During understanding the concept, someone needs a specific ability and strategy. Duffin and Simpson (2000) states that the ability owned by someone during the understanding the concept is expected to be able to re-express the subject communicated to the source of learning, so that could solve the problem.

Polya (1988) mentions four steps to solve the problem, e.g. understanding the problem, planning the action, carrying out the planning, and reflecting the action done. The step expressed by Polya in solving the problem is the activity which can be observed during learning activity and as the measurement of completeness of learning result. According to taxonomy Bloom, the completeness of learning result is differentiated in the field of cognitive, affective, and psychomotor. Anderson, Krathwhol (2001) improves taxonomy Bloom cognitive field into two dimensions: the process of cognition and knowledge. The process of cognition consists of remembering, understanding, applying, analysing, evaluating, and creating. While knowledge is divided into the factual, conceptual, procedural, and metacognition.

Metacognition consists of *meta* and *cognition*. *Meta,* Greek, means after or behind and *cognition* is the process of getting knowledge. (Zahmeister & Neyberg. 1982). Metacognition can be related to the activity of solving problem, knowledge, and cognition or the strategy used during the learning process. At first, the term of metacognition was used by Flavell in 1976. According to him, metacognition consists of knowledge, experience, and regulation. Besides, Flavell stated that metacognition is use as the important element and play an important role in the success of problem solving. However, someone often fail to solve the problem. The main cause of it is the lack of metacognition aspect, especially relating to the steps of problem solving. (Schoenfeld, 1992; Goos, 1995;). In its progress, metacognition can help mathematics thinking process effectively. (Clarke, 2004). While Schoenfeld regards that the difficulty of solving problem is closely related to student's disability to observe and control their process of cognition (Schoenfeld, 1987).Some studies of the relationship between metacognition and problem solving had been carried out, such as Desoete (2001), Lioe (2003), Wilson & Clarke (2004), Cromley (2005), Efklides (2006), Lesh (2007), Panauorra (2009), Kuzle (2011), Molenar (2011), Karan & Irizary (2011), Magiera & Zawojewski (2011), In'am (2012), Praba (2013), Zarimah & Tajudin (2013). The studies have not expressed the characteristic the process of metacognition in detail. Relating to the process of problem, researchers did their studies to describe the characteristic of the process of metacognition to mathematical students in solving mathematical problems. The characteristic of the process of metacognition in the study is described based on *awareness*, *evaluation*, and *regulation*, the components of metacognition.

II. THEORITICAL STUDY

A. The definition of Metacognition

Friedrichs & Hoyt (1976) calls metacognition in term of metamemory, while Veenman (2012) describes it as two main parts: knowledge of metacognition and regulation, and observing metacognition. Knowledge of metacognition is an offer of interaction between someone's knowledge and ability to do his or her duties, characteristic of duties, and strategy used to solve them. Regulation or observation of metacognition is the activities relate to one's planning, monitoring, evaluating, and the process of cognition to control the process. Metacognition is a process which has four important aspects. According to Baker & Brown (1984), the four aspects are self-controlling, planning, evaluating, and monitoring. Wellman (1985) states that metacognition is a form of cognition or a process more than second level of thinking which involves controlling of cognition activities. That's why, metacognition can be said as a someone's thought about thinking of her or his self or someone's knowledge of cognition.

Besides having four aspects, according to Schoenfeld (1992), metacognition is a process of someone's thinking about being thought and interaction among three important aspects: knowledge of thinking process, self-controlling, and intuition. The interaction is very important for the knowledge of process of cognition can assist and control cases around us and select the strategies to increase our further cognition ability. The process of metacognition, according to Schoenfeld, are the ability to question and answering the questions about case, topic and subject, duration of time used by the students to study a certain topic, strategy, method and tactic, level being studied, failure done by the students, and dong revision to the next plan.

Livingstone (1997) defines metacognition as *thinking about thinking*. In other word metacognition is someone's ability to think about he or she thinks, so that metacognition object is thinking process happens to her or himself. Biryukov (2003) expresses that metacognition is someone's prediction about his or her thinking consisting of knowledge, skill, and experience. The knowledge as awareness of what being known, skill of awareness of what being done, and experience as awareness of cognition ability owned.

Davidson & Sternberg (1998), states that metacognition has a very important function and contributes towards the success of problem solving which enable someone to identify and work strategically. Matlin (1998) states that metacognition is a knowledge relating to awareness and cognition process. Wellman (1985) states that metacognition is a form of cognition or two levels or more thinking process involves control to cognition activity. That's why metacognition can be said as someone's thinking of his/her-self or someone's cognition of self-cognition.

Tan (2003) states that metacognition is thoughtfulness refers to think of self-thinking, self-controlling, self-checking, and information processing and how to process the information effectively. Lioe (2003) states that metacognition is someone's awareness of cognition process and stand lone lines to reach a certain goal. Metacognition appears in problem solving whose components are attitude, skill, concept, process, and metacognition. Peirce (2003) defines metacognition in general and specific. In general, metacognition is thinking of thinking. While in specific, Peirce adopts Taylor's metacognition definition saying that metacognition is an appreciation of what is known relating to the ability to make a right conclusion of how to apply someone's knowledge of strategy in a certain situation, and to do it efficiently and perfectly.Taccasu (2008) describes metacognition is a part of planning, monitoring, and evaluating the process of teaching and learning, thinking of what being known, or unknown and control the way to learn involving those two awareness and someone's learning awareness, so that learning will be effective. Mokos & Kafoussi (2013) states metacognition is someone's ability to observe and control her/him-self towards the known thing. During learning process, mathematics is an important thing of a study of students' metacognition process during solving problem focussed on the field of problem solving relating to mathematics.

Based on the definitions above, it can be identified the main meaning of metacognition, e.g. (1) metacognition is soul ability in cognition group, (2) metacognition is the ability to aware, know, the process of cognition happens in someone, metacognition is the ability to direct cognition process in someone, (3) metacognition is the ability to learn how to learn being done in the process of planning, observing, and evaluating, metacognition is a high thinking activity for the activity can control thinking process be doing on someone, and (4) metacognition relating to students thinking process of his/her thinking in order to find a suitable strategy to solve problem, (5) the skill of metacognition is very important to solve mathematical problem, so that the skill need to increase. To increase metacognition skill needs awareness owned by students in each steps of their thinking. Student's awareness is needed to think when solving the problem.

B. The Components of Metacognition

Magiera & Zawojewski (2011) find that metacognition happened during giving assignment in the class. Metacognition happening in the students has three components, e.g. awareness, evaluation, and regulation. During the process of metacognition, it can be seen the appearing activities in every components of metacognition called as types of metacognition activities. The types of awareness consist of what the students know, what the students need to solve the problem, what the students must do, where the students solve the problem. The types of evaluation consist of result evaluation, students' difficulty problem of evaluation, progress ability or understanding evaluation. The types of regulation consist of planning strategy, selecting strategy of problem solving, formulating the goal.

Awareness, according to Wilson & Clarke (2002, 2004), relates to someone's awareness in the process of learning or in the process of solving problem, the content of specific knowledge owned, and someone's knowledge in learning or strategy of solving problem. It is also about someone's knowledge about what is needed, what has done, what can be done in a certain learning or situation in solving the problem. *Evaluation* refers to evaluation made by someone about thinking process, ability and limitation, such as working in a certain situation or as a self-complication. For example, someone can make evaluation about thinking effectiveness done or strategy chosen. *Regulation* in metacognition happens when someone uses his/her skill of metacognition to direct knowledge and thought and refers to individual knowledge in the form of strategy, such as how and why using certain strategies, as well as skill, such as planning, self-correction, decide the goal to optimal the usage of their own cognition source.

Metacognition components stated by Wilson & Clarke (2002,2004) and Magiera & Zawojeski (2011) has indicators as variable and measurement. However, how the process of changes among the components of metacognition has not analysed deeper yet. Sriraman (2003) has considered students about the relationship between their knowledge and what is needed in problem situation given, as Stillman & Gabraith (1998). *Evaluation* has been described and studied concerning the students explicit reflection during the process of solving problem, the function of evaluation in determining the strategy in solving problem. Make a decision in systematic evaluation, alternative plan, and strategy insolving problem (Lester, 1980; Lester, Garafalo, & Kroll, 1989). *Regulation* has been clarified in the form of student flexibility in choosing a solution plan, choosing strategy, and plan implementation improved by Lester (1989), Zan (2000).

C. THE METHOD OF THE STUDY

The study done is qualitative descriptive whose subject is 23 university students. The method and steps of study are (1) giving mathematical problem to the students who have got Differential Calculus as the subject of the study. The mathematical problems are about function downward application to determine maximum and minimum value. The problems have been validated by 2 experts in mathematics and mathematics education. During doing the problems, the subject do and being recorded. (2) Researchers correct the result of students' works based on the answer-key made before. Based on it, subjects of study are classified into high, middle, and low ability students. (3) Give questionnaire.It is given after the students finish doing mathematical problem. It consists of 14 items to measure the process of metacognition happened to the students. It is the improvement of research done by Biryukov (2001), Azsoy & Ataman (2009), Meriam & Idrus (2010), Panaoura (2010), Sengul & Katransi (2013). (4) Doing the interview. It is based on the result of students' works, record,questionnaire answers. It is done to make deeper known about the characteristic of the process of *awareness, evaluation, and regulation*. It is done after students carry out . Interview protocol is arranged by improving the indicators of *awareness, evaluation*, and *regulation*. (5) Doing transcription the record of and interview. The transcription is done for obtaining the data of each of the subject of the s tudy of the characteristic of metacognition process during finishing mathematical problem relating to students ability.(6) Reduce the data. Reducing the data is done by making abstract in the form of summary of data core, process, and statements done by the subject of the study in finishing mathematics problem as well as arranging the data in parts which will be categorised by *coding.* (7) Data analysing, analysing metacognition process each of the subjects of the study though each indicators *awareness, evaluation*, and *regulation*. (8) Data validation, data validation is done using triangulation technique and checking classmates through discussion. Triangulation used is source one, that is comparing the result of observing during the subject finishing mathematical problems, the result of students works, , questionnaire answers, and interview.

D. THE RESULT OF STUDY AND DISCUSSION

The data of the study is in the form of the result of student works of finishing mathematical problems, the record of , the answers of metacognition questionnaire and the interview transcript is studied and analysed qualitatively. The theory design built by the researcher is analysing the characteristic of the student metacognition process in finishing mathematical problems through indicators of *awareness*, *evaluation*, and *regulation.* Based on the theory design, the result of analyse of the study is grouped into category of characteristic of student metacognition process of high, middle and low ability.

During the study, researchers gave mathematics problems to 72 students of Department of Mathematics Education who finished programming the subject of Differential Calculus. The process of metacognition was observed to describe and analysis. Description and analysis done relate to the characteristic *awareness*, *evaluation,* and *regulation.* The result of the initial observation and analysis show that 23 students did the complete metacognition as follows: 6 students are in high ability, 9 students are in middle ability, and 8 students are in low ability.

Based on the result of the study, each of the subjects of the study in each group has characteristic which are relatively same. So hat, there are 6 subjects of data explanation done by the researchers in describing the characteristic of the process of metacognition. They are 2 high ability students symbolized by S-1 and S-2, 2 middle ability students symbolized byS-3 and S-4, and 2 low ability students symbolized by S-5 and S-6.

Next, the characteristic of metacognition process of those three subjects of the study were examined through the indicators of *awareness*, *evaluation*, and *regulation*. The component of *awareness* has 5 indicators. They are the subject of the study re-think of what was known about given mathematics problems given (A1), re-think the question of mathematical problems and related it to the similar problem gotten and done before (A2), re-think the undone thing (A3), re-think the next steps to do (A4), and re-think the steps done (A5).

The component of *evaluation* has 5 indicators. They are the researchers re-think the way to solve the problems (E1), re-think the order and steps to do (E2), re-check the answers (E3), re-think whether the answers are right or wrong (E4), and re-think the failure done in answering mathematical problems which were given in the last way (E5).

The component of *regulation* has 4 indicators. They are the subjects of the study re-think and make a plan to finish mathematical problems (R1), re-think the different way done in answering mathematical problems (R2), re-think of what will do after finishing answering mathematical problems (R3), and re-think how to change the way. The process of the happening of metacognition can be described as follows:

A. The Process of High Ability Students Metacognition

The subject of the study in high ability S-1 and S-2 have same characteristics of metacognition process. During the metacognition process, S-1 and S-2 show the activity that describes the characteristic of component indicators *awareness*, *evaluation*, and *regulation*. When finishing mathematics problems, the indicators of mathematical problems appeared in order: A1, A2,A3, A4, A5, E1, E2, E3, E4, E5, R1, R2, R3, and R4.The order of appearing indicators on S-1 and S2 can be seen on the figure 4.1

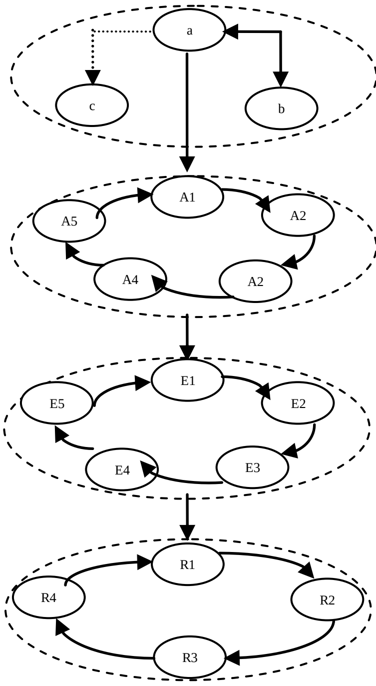

Figure 4.1: Metacognition Process S-1 and S-2

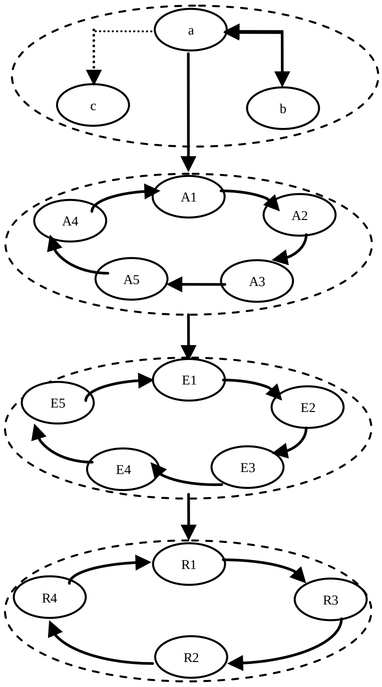
B. The Process of Middle Ability Students Metacognition

The middle ability subject of the study, S-3 and S-4 carried out metacognition process with complete indicators but disorder. When finishing the problems, the indicator in S-3 appeared in order A1, A2, A3, A5, A4, E1, E2, E3, E4, E5, R1, R3, R2, and R4. The indicator in S-4 appeared in order A1, A2, A3, A4, A5, E1,E2, E3, E4, E5, R1, R2, R4, R3.

The order of appearing indicator in S-3 can be seen in figure 4.2 and the order of appearing indicator in S-4 can be seen in figure 4.3



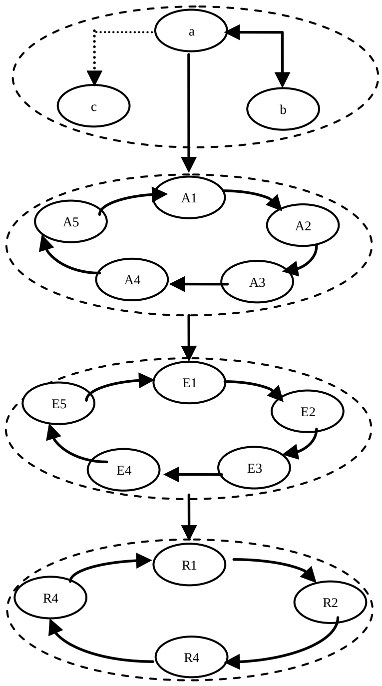


Figure 4.2: The process of Metacognition S-3 Figure 4.3: The Process of Metacognition S-4

ISBN 978-602-74529-0-9

C. The Process of Low Ability Students Metacognition

The low ability subjects of the study are S-5, and S-6. The changes of metacognition process S-5 and S-6 showed the activities that described the characteristics of indictor *awareness*, *evaluation*, and *regulation*. When finishing mathematical problems, the indicator in S-5 appeared in the order A1, A3, A2, A4, A5, E1, E2, E3, E4, R1, R3, R2, R4, R3.The order of appearing indicator in S-5 can be seen in figure 4.4 and the order of appearing indicator in S-6 can be seen in figure 4.5

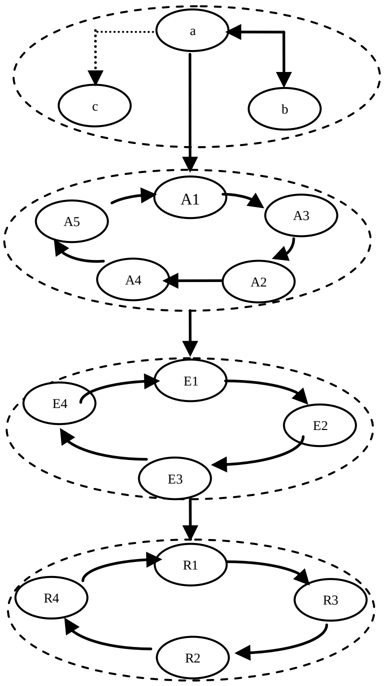

Figure 4.4: The process of Metacognition S-5

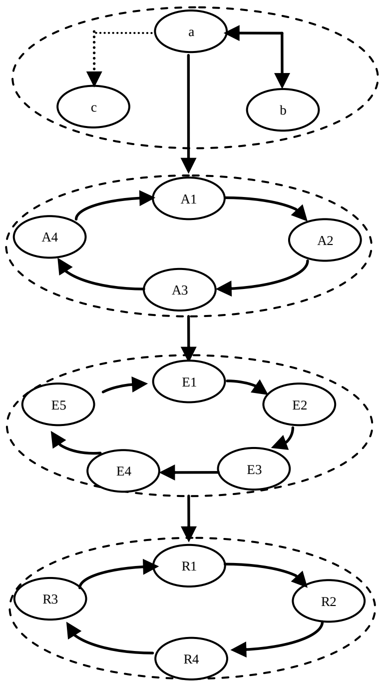

Figure 4.5: The Process of Metacognition S-6

The finding of the result of the study can be related to the previous theory as the basic of the study. If relating to the opinion of Wilson and Clarke (2002, 2004), each of the characteristic of the components are activities concerning with someone's ability to think of what he/she has done when finishing the problem. The problem of the study is how the subject of the study can find out the believed ways as the answers of the mathematical problems. The belief of the subject of the study is based on the process of evaluation and regulation done and as a part of abilities to observe and control him/her-self toward something known. Self-controlling can be done when finishing the problems (Mokos & Kafoussi, 2013). In a accordance with the indicator during the process of metacognition happened, it can be seen that the activities are the types of metacognition activities.The type of awareness is what the students know, what students need to finish the problems, what the student must do, where the students were. The type of evaluation activities result of evaluation, grading of students' difficulties problems, grading the improvement, ability, and understanding. The type of regulation activity is the strategy of planning, selecting the strategy, formulating the goal. Magiera & Zawojewski (2011).

E. CONCLUSION

Based on the data analysis, it can be inferred that high ability students are in complete and order of their characteristic of metacognition process, middle ability students are in complete and disorder of their characteristic of metacognition process,while low ability students are in incomplete of their characteristic of metacognition process.

The complete and order of characteristic of metacognition process is in S-1 and S-2, the complete and disorder of characteristic of metacognition process is in S-3 and S-4, and the incomplete characteristic of metacognition process is in S-5 and S-6 can be in detail as follows: The component *awareness* with A1 brings out 6 characteristics, A2 brings out 7characteristics, A3 brings out 5characteristics, A4 brings out 8 characteristics, and A5 brings out 4 characteristics. The component of evaluation with indicator E1 brings out 6 characteristics, E2 brings out 6 characteristics, E3 brings out 6 characteristics, E4 brings out 4 characteristics, E5 brings out 4 characteristics. The component of

regulation with the indicator R1 brings out 5 characteristics, R2 brings out 3 characteristics, R3 brings out 4 characteristics, R5 brings out 6 characteristics.
The explanation of the order of indicator of 6 subjects of the study can be clarified as in the following table.

TABLE 1: The Order of Metacognition Process of Subject of Study

No.	The Subject of the Study	The Component of Metacognition	The Order of Indicators
1.	S-1 and S-2	*Awareness*	A1, A2, A3, A4, A5
		Evaluation	E1, E2, E3, E4, E5
		Regulation	R1, R2, R3, R4
2.	S-3	*Awareness*	A1, A2, A3, A5, A4
		Evaluation	E2, E1, E3, E4, E5
		Regulation	R1, R3, R2, R4
3.	S-4	*Awareness*	A1, A2, A3, A4, A5
		Evaluation	E1, E2, E4, E4, E5
		Regulation	R1, R2, R4, R3
4.	S-5	*Awareness*	A1, A3, A2, A4, A5
		Evaluation	E1, E2, E3, E4
		Regulation	R1, R3, R2, R4
5.	S-6	*Awareness*	A1, A2, A3, A5
		Evaluation	E1, E2, E3, E4, E5
		Regulation	R1, R2, R4, R3

Students' Anxiety Facing Computer Based Test (CBT) System of National Examination

Eny Sulistyaningsih
Mathematics Education, Yogyakarta State University
enylistya@gmail.com

Abstract—National examinations in education sometimes become a debatable issue among various groups. In response, the government made changes for the better education in national examination system. National examination that was originally done in written form (Paper Based Test/PBT) changed into a computer system or (Computer Based Test/CBT) in academic year of 2014/2015. Changing the PBT national examination into the CBT national examination was because the CBT national examination had more benefits than the other. However, the limited human resources in the management of test facilities that support the implementation of CBT national examination became one of the things needed to be considered and paid attention to, especially for students who would have the CBT national examination. It was a new thing that triggered students' anxiety, not to forget mentioning that the examination itself was already made them anxious. This study was a survey done by using questionnaire method given to the senior high school students in 3rd grade in Yogyakarta province. The results of this study are: (1) generally, students' anxiety is in medium level. Science students' anxiety in the idea of having CBT system for the national examination is medium level, and it is in similar level for the social students; (2) there is no relation between the students' anxiety with their major (natural or social science).

Keywords: *students' anxiety, computer based test, national examination*

I. INTRODUCTION

Education is important for the sustainability of every individual. Therefore, the quality of education must be improved for the better. One of the forms of education evaluation in Indonesia is by conducting the national examination. National examination is one of the policies made by the Indonesian government in terms of education, especially in the implementation of the final assessment at national level of education. Assessment has an important role in the educational process. It is also considered as an important measurement tool in evaluating the student's performance. In addition, the assessment is important as a process of obtaining information that is used to make decisions about the students, the curriculum and programs, and the educational policy [1]. The national examination is a form of evaluation of students, the education unit, and educational programs carried out by independent institutions on, thorough, transparent, systemic, and done on a regular basis, to assess the achievement of national education standards [2]. The national examination is the measurement and assessment of national competency attainment in certain subjects. National exam SMP / MTs, SMA / MA / SMAK / SMTK and SMK / MAK can be done through Paper-Based Test (Paper Based Test) and/or Computer-Based Test (Computer Based Test) [3]. However, not all of the schools in Indonesia implement the new CBT form of national examination. The CBT system is done gradually by certain schools that meet the requirements.

CBT national exam has already been implemented in 2014 in Indonesia-Singapore junior high school and Indonesia-Kuala Lumpur junior high school. The result was quite encouraging that it pushed the government in improving the students' literacy to ICT (Information and Communication Technology). CBT National examination system is an effective solution for carrying out the evaluation or educational assessment conducted on large number of students. This is also explained by the results of the research that the validity of web-based CBT tests given to large number of respondents is proved [4]. The statement that CBT test or exam is effective for educational evaluation with large number of participants is in line with the policy of the Indonesian government which is about the CBT national exam. However, schools to implement the CBT system are required to submit the confirmation on the school's readiness of implementing the system. Furthermore, a process checking is also essential, done by the official verification to ensure the school's readiness on facilities and infrastructure. The verification process covers the availability of computer laboratory, networking, switching devices, internet access, UPS, generators, server, client, and other supporting infrastructure [5]. The benefit of CBT national exam system is on the time division. It is divided into three sessions in a day. One subject is done in each session, resulted in a better integrity of the students. This is because the questions of examination appeared on each computer is different [6]. In addition, the different examination question for each student is proven to decrease cheating drastically [7]. Nonetheless, there are some students who may be anxious with the new system [8]. It is due to the general computer literacy level of the students.

Anxiety can be observed from the attitude or behavior of the person, on this discussion is the high school students. High anxiety of every level is observed from most of the students, caused by the CBT system implementation for the examination [9]. The test is similar with the national exam. National exam has positive and negative impact. One of the negative impacts is increasing students and teacher anxiety [10]. Anxiety happened to students will lead to certain traits or symptoms. Certainly, anxiety produces physical symptoms. In fact, some people suffer particularly from the changes in appetite, sleep, energy, or pain, when they are reported to be lost in their own thinking, showing behavior problems. In other opinion, Chess &Hassibi [11] stated that anxiety is defined as an unpleasant situation that is usually perceived as a fear of something that will happen and feeling irritable accompanied by anxiety, fatigue, and a variety of somatic symptoms such as headaches and stomach aches. Anxiety is an individual experience related to mental tension alarm as a result of public reaction and inability to confront the problem or their sense of security. Anxiety is accompanied by psychological and physiological signs. Psychological signs are including shaking, sweating, and increased heart rate. While signs of psychological panic are including tense, confused, and cannot concentrate [12]. Signs of emotional anxiety caused by examinations are over whelming feelings, helpless and hopeless, ashamed and worthless (feels like a failure), panic, unable to concentrate, complained of being ill, have an angry outburst or tantrum, fatigue, and difficulty in sleeping the night before the test [13]. In this case, one kind of test or exam that may cause anxiety in students is national exam that students at the end of every level of education should face. Now with the new CBT system of national examinations, the students are prone to experience higher anxiety. This statement is the idea of this research on studying the anxiety of the high school students in Yogyakarta regarding the implementation of CBT system on national examination.

The problem formulations of this study are: (1) how does the level of anxiety of high school students in Yogyakarta province in facing the CBT national examination? (2) Is there any influence between the students' major (natural or social science) and the anxiety level?

The aims of the study are: (1) to determine the anxiety level of the high school students in Yogyakarta province on the CBT national examination, (2) to determine whether there is any influence of major, which were natural science and social science, with their anxiety level. The benefits of the study are: (1) giving contribution to the conceptual studies on the effect of the government policy on the CBT system for national examination to the anxiety of high school students in DIY in facing mathematics national exam, (2) giving benefit to the schools because it could be used as the consideration for giving better guidance to the students in facing the national exam, so that their anxiety could be controlled, (3) being useful as information and knowledge for academic use and public use in general about the anxiety of high school students in Yogyakarta province caused by the implementation of CBT on the national examination, (4) being used as a basis for similar research in other provinces or for similar research with different variables.

II. RESEARCH METHOD

A. *Research Design*

This study was a survey conducted by using questionnaire created according to the theory of students' anxiety in facing CBT national examination. This study described the results of the analysis of the students' anxiety level.

B. *Research Subject*

The population in this study was all students of class XII (3rd grade) in Yogyakarta province which senior high school implemented CBT system for the national examination. Selected samples were seven schools in four regencies and one municipality. The regencies were Sleman, Bantul, Kulonprogo, Gunungkidul regencies, and also Yogyakarta municipality. The samples were 318 students, consisted of

167 science students and 151 social students. A science class and a social class were selected randomly from each school.

C. Research Procedure

The study was conducted on February 17th to March 5th, 2016. This study was a survey conducted by using questionnaire as data collection instrument. The questionnaire used five alternative options, which were always/strongly, agree, often/agree, sometimes/hesitations, rarely/not agree, and never/strongly not agree. The scale used was the Likert scale, in the range of 1-5. The higher the questionnaire score of the student, the higher the students' anxiety was.

After going through the validation phase, the questionnaire then was tested to determine its reliability. The questionnaire reliability was 0.824, and KMO's score was 0,720. Furthermore, the questionnaire was given to selected respondents or samples to obtain the research data.

D. Data Analysis

Data analysis was conducted after the data had been obtained. To analyze the data, first of all, it was analyzed by using central tendency analysis. It consisted of the average, median, mode, standard deviation, maximum score, and minimum score. The data then was analyzed to determine the level of anxiety of the high school students. It was analyzed by using the criterion table of anxiety score. The last, the data was analyzed to find out the anxiety level of the sample, both from the science and social studies majors. It was focused on whether there was any influence of major, which were natural and social science, with the anxiety of high school students in Yogyakarta province. The data was analyzed by using different average test (independent sample t-test).

III. DISCUSSION

The discussion in this study consisted of two main discussions. The first discussion will be the discussion as a whole on the level of anxiety of high school students in Yogyakarta province in the CBT national exams. It will be adapted to table criteria. The second, the discussion will determine whether the difference in major, whether it is natural science or social science, could influence the anxiety level of the high school students.

A. Anxiety Level of High School Students in Yogyakarta Province Facing CBT National Exams

Data description of high school students' anxiety is shown in Table 1.

TABLE 1. DATA DESCRIPTION OF STUDENTS' ANXIETY FACING CBT NATIONAL EXAM

	Natural science class	**Social science class**	**Total**
Number of students	167	151	318
Average	86,521	84,099	85,31
Median	88	84	87
Mode	88 and 89	83	88
Standard Deviation	12,584	12,907	12,775
Maximum score	118	115	118
Minimum score	48	45	45

The table shows that the average level of the high school students' anxiety for natural science major is at 86.521 and the average level of the social science students' anxiety is at 84.099. It is clear that the average level of anxiety of natural sciences major is higher than the social sciences. Reflected in the table also the median and the mode of natural science students are higher than the social students'. Moreover, from the standard deviation, it can be seen that students in social science class scored higher than the students in natural science class. The maximum and minimum scores of natural science students are also higher compared to the students of social sciences'. However, both majors have similar range of score, exactly a score of 70.

Overall, the number of students 318 provides an average 85.31, median 87, mode 88, and standard deviation 12.775. As for the maximum value and the minimum value includes both science and social groups, the maximum value is 118 and minimum value is 45. The values can be categorized based on the criteria for the anxiety level of high school students in Yogyakarta province facing the CBT national examination by using the criteria as served in Table 2 [14].

TABLE 2. CRITERIA OF STUDENTS' ANXIETY

Interval	Category	Criteria
$Mi + 1{,}5Si < X \leq Mi + 3Si$	$120 < X \leq 150$	Very High
$Mi + 0{,}5Si < X \leq Mi + 1{,}5Si$	$100 < X \leq 120$	High
$Mi - 0{,}5Si < X \leq Mi + 0{,}5Si$	$80 < X \leq 100$	Medium
$Mi - 1{,}5Si < X \leq Mi - 0{,}5Si$	$60 < X \leq 80$	Low
$Mi - 3Si < X \leq Mi - 1{,}5Si$	$30 < X \leq 60$	Very Low

Based on Table 2, it can be stated that the average level of anxiety of the natural science students is 86.521. The category is medium. Moreover, the average level of anxiety of the social science students is 84.099. The category is also medium. In general, the average level of anxiety for both of the majors is 85.321, which is categorized as medium criteria. CBT national exam is possibly a way of implementing the new exams for some students, despite of the fact that there will possibly be some students who are not accustomed to using the computers. In fact, the results of the study stated that the student anxiety is at the medium level. It can be concluded that the students are generally able to overcome a sense of anxiety in them, so that the students will have them in control.

The anxiety that these students are feeling when it comes to the CBT implementation for the national examination can also be a positive energy when it is not excessive. It can be used as encouragement for students to get better exam results. Students with high level of anxiety will have lower cognitive achievement, while students with low anxiety will have higher cognitive achievement [15]. In the other hand, excessive anxiety may cause a psychological impact on students. The test results may also not reach its optimum possibility.

The results are consistent that the anxiety experienced by students regarding the implementation of national examination is actually a strong cause that motivates the students to learn and try (79.1%) [16]. The high students' motivation of learning and students effort will bring good result. Motivation and effort being mentioned will be able to help the students control and lower the students' anxiety in facing the examination. It can also lead to better concentration while doing the examination, for one of the symptoms anxiety can cause to an individual is a low level of concentration or being "blank" during the test [17].

B. Analysing Whether There Is Any Relation between The Students' Major and The Anxiety Level of High School Students in Yogyakarta Province in Facing CBT National Examination

This analysis is conducted by using different average test (independent sample t-test). Before analyzing, the data must fulfill the assumption test. By means assumption test here are normality test and homogeneity test. The hypothesis used in the test for normality is as follows:

H0: Data distribution is normal

H1: Data distribution is not normal

The result of the analysis showed that the Kolmogorov-Smirnov normality for the data of science students' anxiety is 0.062. It is greater than 0.05. Its consequence is H0 is accepted. It means that the data distribution is normal.

The next assumption is homogeneity test. Hypothesis used in the test for homogeneity test is as follows:

H0: Variance data of science and social groups is homogenous

H1: Variance data of science and social groups is not homogenous

By using Levene's test, the result of the analysis is 0,711. It is greater than 0.05. Its consequence is H0 accepted. It means that the data variation of science and social groups is homogenous.

After testing the assumptions, the data was continued to be analyzed by using different average test. The analysis is done by using the independent sample t-test. The analysis made use of the data of high school students 'anxiety in Yogyakarta province facing CBT national exams in natural and social science. This test aimed to determine whether or not the major of the students have influence to the anxiety level of senior high school students. The hypothesis in this analysis is:

H0: $\mu 1 = \mu 2$ (There is no significant influence between the anxiety level and the major, natural and social science, of the senior high school students in Yogyakarta province regarding the CBT national examination)

H1: $\mu 1 \neq \mu 2$ (There is a significant influence between the anxiety level and the major, natural and social science, of the senior high school students in Yogyakarta province regarding the CBT national examination)

The result of the analysis is significant with the value of 0.091. It is greater than 0.05. Its consequence is H0 accepted. It means that there is no significant influence between the anxiety level and the major, natural and social science, of the senior high school students in Yogyakarta province regarding the CBT national examination. Students majoring in natural or social science feel the same anxiety as they face the CBT national exam. The level of anxiety faced by both major is also not very different. This is because there is no difference in treatment regarding the implementation of CBT national examination between students of both major. Natural and social science carry the same CBT test for preparation (known as try out test), the same implementation schedule, the same schedule for the result, the same possibilities that can occur when the CBT national exam is implemented, such as problems about the electricity, computers, or networking. Besides that, each of the students from both majors has personal goals that must be achieved on the national exam. The determination of these targets can trigger their anxiety, and it appears on each student of both majors. In addition, students of both groups had to control their anxiety when facing the new computer-based national examination.

IV. CONCLUSIONS AND SUGGESTIONS

A. Conclusions

Based on the research results, there are two points that can be concluded from this study. The first is that the anxiety level of the senior high school students in Yogyakarta province in facing CBT national exams is categorized into the medium level. Students of natural science and social science major's anxiety level is also concluded to be in medium category. The second, there is no significant influence of major, which were natural science and social science, with their anxiety level of the senior high school students in Yogyakarta province.

B. Suggestions

Regarding this study, there are some suggestions. For a better study conducted in the future, it is suggested to the researcher to have bigger number for the sample and population, so that the scope of the research can cover wider research range. Moreover, it is suggested to have more variables in the study, so that the research can be seen in a wider point of view.

Increasing Higher Order Thinking Skill to Build Student's Character by Using Mathematical Reasoning

Evvy Lusyana[1], Magdalena Wangge[2]
[1]Yogyakarta State University (Magister of Mathematics Education)
[2]Yogyakarta State University (Magister of Mathematics Education)
evvy.himalaya@gmail.com

Abstract— This paper discusses about mathematical reasoning can increasing higher order thinking skill which can build student's character while learning process. In the process of mathematics learning, students will be faced on routine and non routine problems, so they need critical and creative thinking skills to solve the problems. Mathematical reasoning is one of goals from learning mathematics. There are five various types of mathematical reasoning, such that; 1) Algebraic reasoning, 2) Proportional reasoning, 3) Statistical reasoning, 4) Geometrical reasoning, 5) Probabilistic reasoning. With mathematical reasoning, teachers can provide space for students to think logically in understanding mathematics concepts and consider all the possibilities that exist to solve problems. In the process of finding the solution of this problem, students will require unusual thinking skills are often referred to as higher order thinking skills. Improved way of thinking in the process of mathematical problem solving can build performance and moral student's characters such as discipline, honest, responsible; never give up etc. Because there are six pillars of character such that, 1) Trust, 2) Respect, 3) Responsibility, 4) Fairness, 5) Caring and 6) Citizenship. If this characters be applied to life, it can helping students to facing developments and global challenges.

Keywords:*Higher Order Thinking Skill, Mathematics Reasoning, Student's character*

I. INTRODUCTION

The rapid growth of science and technology has made free flow of information accessible to everybody. The fact has shown that government is incapable of setting a certain limit to the accessibility and censorship of information which resulting in easy access to misbehavior. Weak parental and societal guidance in selecting information set the students as the only ones to decide for themselves of whatever information to be accessed. Brawling as an instance is a common reality presented by media technology. As this rampant phenomenon is shown, it then becomes a trend of the youth nowadays. Thus, like a tuberculosis, it spreads everywhere instantly from a certain place to another and from an educational institution to another.

Indeed there is a lot of accessible information either good or unhealthy ones whose unconfined accessibility can lead students astray. Consequently, the presence of the advantages and disadvantages of free access to this information influence the formation of students' characters. Aside from the problems arisen from the free access to information, the fact that human persons are relational being, there are indeed problems emerged in the relationship either with persons around the place where they live, with other students at school or with whoever they come in contact with. What is saddening nowadays is not anymore problems emerged from actual relationship with fellow students but rather problems encountered within virtual reality. The interaction and involvement of students with the latter reduce the necessary encounter with fellow students at school which basically formative.

However, regardless the above mentioned detrimental situations encountered by students, the government still has great hope for the schools which take into consideration the formation of students' characters. With the issue of Permendiknas No. 41 Tahun 2007 which talks about standard process, where in the learning process beginning from introduction, core substances, and conclusion, these three parts are taken into consideration so as to contain and give priority to expected values. This *Student Centered Principle* as it is called is above all aimed at the assimilation of values in life by students. Aside from that, teachers are expected to become living exemplars of how to live out of the values that they impart to the students.

Fundamentally in learning process the expected values to be achieved by students are integrated in every subject in the school not to exclude in Mathematics. The latter is the most common subject offered in school at any level. The main characteristic of this subject is not a usual skill as found in any other subjects. Its skill is called *Higher Order Thinking Skills* (HOTS). *Higher Order Thinking Skills* (HOTS) is a thinking process of how to find answers or solutions in the midst of difficult and tricky situations by way of taking and connecting new and stuck knowledge so as to make them wider knowledge. HOTS in Bloom's taxonomy, falls on the category of cognitive analysis, evaluation, and creation. This cognitive analysis and evaluation falls under critical thinking while cognitive creation is under creative thinking [1].

Indonesia is not included in the number of countries which are considered as well-versed in science and technology. This is because of the low achievements of our education. This low achievement is gauged from the ability of students in answering questions which demand higher thinking skills. Based on the datum given by PISA in 2012, from among 65 countries in the list, Indonesia is in the 64th rank when it comes to science and mathematical skills. Indonesian students are used only with common questions on first and second levels which consequently resulting in lower acquirement of grades when they are given questions based on PISA standard which are actually ranged from first to sixth level and basically contextual in their characters.

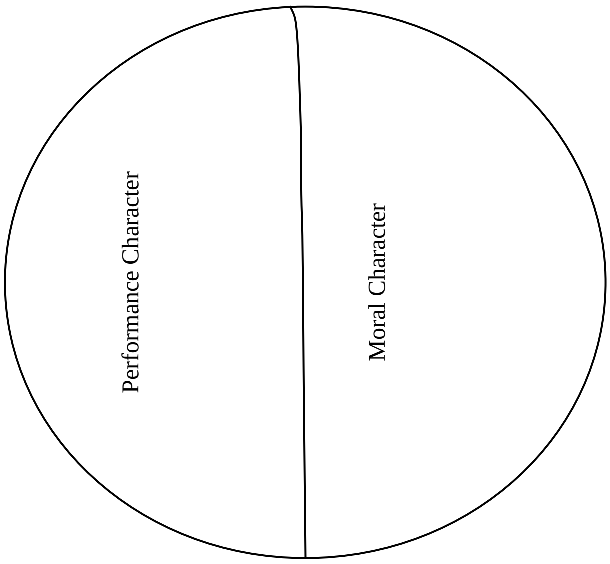
The government then applies 2013 curriculum with the perspective of facing the demands of education in this globalization era. The theme of the development of the said curriculum is a curriculum which is capable of producing Indonesian individuals who are productive, creative, innovative, and affective through the strengthening of good positive values, skills, and integrated knowledge. Competent attitudes expected from the students are those attitudes that mirror piety, honesty, high regard for discipline, responsibility, care, courteousness, responsive and pro-active behavior. Besides, students are expected to acquire factual, conceptual, procedural and meta-cognitive knowledge in different disciplines for them to be knowledgably competent. The latter demands students to possess the ability to act effectively and creatively so as to put into practice in the daily life methods and theories acquired in school.

The learning system contained in 2013 curriculum stresses the indispensability of HOTS. Students with HOTS are not only those who memorize to the letter the information imparted at school but they also have the ability to put them into practice at daily bases. They possess analytic mind as well. Mathematical reasoning offers new efficacious ways to build into awareness and to express ideas about varied and wide phenomena in this globalization era. Thus, students with analytic minds tend to cling on pattern, structure, and regularity or irregularity either in concrete situations of life or hypothetical ones.

II. STUDENT'S CHARACTERS

Human characters are different for each person, as well as student's character in the classroom. These differences are influenced by many factors; one of the factors is teacher's role in learning activities in the classroom. Teacher's role in the class may affect student's character, so teacher are expected to take more time to observe and learn student's character. Thus, teachers can choose appropriate learning methods to be able to build student's character. Characters are special markers that distinguish each person, or individual's qualities that made the difference. Naim [1] wrote in his book that character is a picture that shows attitude of right and wrong behavior, good or bad behavior. Characters can be classified into attitudes, behavior, motivation and skill, from those Naim wrote that characters include religious attitude, honesty, tolerance, caring, democratic, disciplined, hard working, independent, high curiosity, never give up, critical and creative. Hildebrandt & Zan [2] wrote that there are six pillars of character such that, 1) Trust, 2) Respect, 3) Responsibility, 4) Fairness, 5) Caring and 6) Citizenship. That opinion indicates that character will support human social life then can be used to deal with developments and global challenges. Through learning, students are expected to have a character that can support their social life. So, mathematics teacher are expected help student to build their characters through the process of mathematics learning.

Characters cannot be formed in short time, when teacher want to building the student's character they must be patient. Build student's character through mathematics learning is not easy, it is requires long time and continuously. However, character which build in this learning will be rooted on student's life. For example, when teacher divides students into small groups and ask them to discuss an issue then the characters that appear are tolerance, caring, curiosity and creative. Then, when the students were asked to convey their discussion's result, the characters that appear are democratic, critical and creative. When teachers provide an opportunity for students to corporate their abilities then the characters are formed will be better. Summarize the Piaget's opinions [2] that students who intellectually passive then they do not have independent themselves, so teachers are asked to give them a chance to be active intellectually.



Picture 1st. Performance and Moral Character by Matthew

Learning mathematics which given by teachers can be used as bridge for students to build their good characters. When teachers provide opportunities for students, it will minimize rebel's attitude or minimize moral damage that happens now days. As written by Matthew Davidson [2] in his research that characters are defined into two sections interconnected, there are performance character and moral characters. Performance characters include persistence, tenacity, work ethic, positive attitude, ingenuity and disciplined which used to support academic's activities, work and life. While the moral characters include integrity, fairness, caring, respect and cooperation are needed in interpersonal relationship. So, to able to treat other students with good attitude, then a student must be has a good character too. Mathematics teachers can also manage their learning mathematics to be able to support characters building as exemplified advance.

Students have different characteristics and should be used as one of the focus of attention in learning, so that optimal learning results obtained. Therefore, at least the teacher must know the character of each student. By knowing the character of their students, teachers will gain some of the benefits that would be used as one of the cornerstone in the implementation of learning activities. The benefits of such teachers can recognize the ability of the students, the student learning experience, the social background of students, the level of development and the needs of students, as well as the level of mastery of previous students.

Learning mathematics is a process organized by the teachers to teach the students to acquire science and math skills. When we ask a student for expressing his opinion about learning math, then it will be a lot of complaints that sounds boring math lesson, not interesting, even too abstract, so that leads to the results of learning math. Teach mathematics is not easy due to the fact that the students experience difficulties in learning mathematics. To avoid those things, math learning should be based on the characteristics of the students.

III. HIGHER ORDER THINKING SKILL

Bloom's taxonomy is considered as the basis for the classification of thinking skills. In revised Bloom's taxonomy, analytic, evaluative and creative skills are categorized as *transferring* or processing which is part of higher order thinking skills while the ability to remember, to comprehend and to apply the learning are categorized as *recalling* which is part of lower order thinking skills [3].

The school's curriculum which focused to develop the human resources (HR) includes the cognitive, affective and psychomotor. Higher Order Thinking Skills is one of the resources so that knowledge and skills must be improved and developed. Therefore, one indication the improvement success of human resources in the education field are students have a high level of skill is good, because the primary purpose of learning in the 21st century is to develop and enhance the student's HOTS. Especially in the math lesson HOTS is one of the priorities of developed, following Permendikbud No 64 Tahun 2013 about standard contents for mathematical subjects stated that math needs to be given to all students ranging from elementary school to equip learners with the ability of logical thinking, analytical, systematic, critical and creative & ability of problem solving and teamwork.

However, based on the results of TIMSS written by Mullis.at.al (2012) the position of Indonesia on the domain of cognitive reasoning and domain content numbers each are on the last ranking and rating to 37 from 43 countries. This suggests that the ability of the learners on the low, so the reasoning needs to be improved by making the process of learning mathematics based HOTS. In addition, based on the results of the survey conducted Musfiqi [4] to 20 Junior high school mathematics teacher in Jepara regency, found that 75% of respondents initiated their math learning with the introduction of definitions and formulas without connecting it to solving problems in a variety of contexts. While it 90% of the respondents had never planned nor implement learning that emphasizes on thinking skills. As a result of students ' thinking ability has not been directed to the level of the higher thinking skills, including the ability to think critically and creatively in problem solving.

Based on the above facts, it can be concluded that the ability of higher-order thinking students remains relatively low; this is due to the HOTS have not applied in the process of learning mathematics processed. Therefore, the perceived need for a learning process oriented enhancement as well as granting HOTS questions based HOTS. In line with that, based on the principle of teaching from NCTM (NCTM, 2000, p. 20) "effective mathematics teaching requires understanding of what students know and need to learn and then give the challenge and support them to learn them well".

According to Bloom [5], Higher Order Thinking Skills is a process that involves mental, such as classification, induction, deduction, and reasoning. Stein and Lane [6] defines a high level thinking is the complex thinking, non-algorithmic thinking to solve a task in which there is not a predictable, well-rehearsed approach or pathway explicitly suggested by the task, task instruction, or a worked out example. According Stein, higher-order thinking using a complex thinking, non algorithmic to complete a task, there is that unpredictability, uses a different approach with existing tasks and different from the example. Higher-order thinking is the ability to complete tasks where there is no algorithm that has been taught, which require justification or explanation and have more than one possible solution [7]. High level thinking skills learners will produce: proficiency students in problem-solving strategies to become good, confidence level learners in mathematics increased, and the learning achievements of students in non-routine problem that demands high level thinking skills increase.

Mc Loughlin and Luca [8] state that HOTS means the ability to comprehend the information beyond what is given, to adopt critical disposition, to possess the meta-cognitive awareness, and to solve problems. HOTS is an ability to connect, manipulate, and transform knowledge as well as already possessed experience so as to think critical and creatively in order to decide for the necessary things to do and to solve problems in any new situations. According to Susan M. Brookhart [9], HOTS is classified into three categories. Those categories are which define HOTS as *transferring* in matter of critical thinking and in problem solving.

Based on the definition, higher order thinking skill leads to problem solving skill. According to Woolfook [10], problem solving skill is a skill of a student in directing his/her thoughts to solve problems through the gathering of facts, analysis of information, putting together the many alternatives of solving them, and selecting the way the most effective means to solve the problems. Thus, HOTS is a one's skill to criticize, to find solution to problems which are complex and to be able to give several alternative solutions over a certain problem by way of manipulating different information acquired. Human persons are not the only ones who can solve problems but solving problems is identical to human activities. On the basis of the opinions above, then it can be inferred a high level thinking skills is thinking skills at a higher level than just memorizing content and involve diverse thought processes of analyzing, evaluating and creating a conditioned in the process of mathematical problem solving.

According to Krathworl & Anderson in Arifin [11] Practice, indicators to measure higher-order thinking skills include: (1) analyze: (a) Distinguish (differentiating) include the ability to distinguish the parts of the overall structure of the form accordingly. Distinguish happens when students discriminate information relevant and irrelevant, what's important and not important and then pay attention to the information that is relevant and important. (b) Organize (Organizing) include the ability to identify the elements together into a structure. The process of organizing occurs when students build relationships a systematic and coherent (related) between pieces of information. (c) Attributing is the ability of students to mention about viewpoints, refraction, the value or the intention of concerns. (2) Evaluate: (a) Checking is the ability to test the internal consistency or error in operation or the outcomes as well as detect the effectiveness of the procedures used. (b) Criticize is the ability to decide the result or operation based on specific criteria and standards, and detect whether the results obtained on the basis of a procedure are approaching the correct answer. (3) Created: (a) Formulating hypothesis or make hypothesis, involves the process of describing the problem and make choices that meet certain criteria. (b) Planning process involves plan a method of settlement of an issue that is in accordance with the criteria of the problem. (c) Producing involves the process of implementing a plan to solve a problem that meets certain specifications.

Newman and Wehlage [12] state that HOTS require students to requires students to manipulate information and ideas by way of transforming their meaning and implications, such as when students combine facts and ideas in order to synthesize, generalize, explain, hypothesize, or arrive at some conclusion or interpretation. Realizing that knowledge is wide, with HOTS students will learn more profoundly and comprehend the concept better. This is definitely in accordance with substantial character of every subject when students are expected to be able to express their understanding over the matter with profundity. With HOTS, students will be able to differentiate ideas with clarity, to stand the arguments soundly, to solve problems, to construct due explanations, to hypothesize, and to comprehend complex matters clearly. HOTS is learnable, it can be taught to students, and with it, students' character can be formed accordingly. Furthermore it is said that there is indeed difference between rote learning with that of HOTS which applied higher order thinking. To think means to use one's analytical, creative, and applicable skills. This sort of thinking is what is needed in one's daily life.

It is also said that with HOTS students can become independent thinkers, hence the arguments uttered indicates the quality of his/her abilities. Applying HOTS as one of the means of learning leads to the productive learning especially in socio-cognitive interaction, such as: (1) giving and receiving help, (2) changing and completing information, (3) elaborating and explaining concepts, (4) sharing of knowledge with co-students, (5) mutual giving and accepting correction, (6) collaboratively doing assignments, and (7) rending necessary contribution in overcoming challenges. With the approach brought by HOTS, students are invited to actively think especially in the problem solving [13].

IV. MATHEMATICS REASONING

Learning school mathematics is assumed to be given to a student who never know mathematics before. According to Joyce and Well [14] that the teacher's duty in the learning process is to assist students to finding information, ideas, skills, value, way of thinking, as well as looking for good way of learning and express themselves. Having regard to learning's rule, teachers may be able to evoke right

ISBN 978-602-74529-0-9

way to makes mathematics reasoning. In Permendikbud No.22 Tahun 2006; that students are expected to use reasoning, logical thinking, analytic, systematic, critical and creative in solving mathematical problems. Thus, the reasoning ability is one of important focus in learning mathematics, because if the students have not been able to reasoning, then they will difficult to solve the problems presented. Mathematics reasoning is not an ability that can be seen in a short time. Students, who are able to reasoning properly, usually trained in completing various forms of problems presented by teachers, both problems are simple to complex problems. Given the problems with the conditioning routine, non mathematical reasoning students will be expected to build and can be applied to the problems faced in the future.

Each student needs reasoning in order to achieve the desired learning objectives. Reasoning has not been clearly defined, but if makes hypothetical analytic reasoning means controlling and developing the thought of a thing until became clear. Then, when drawn in mathematical it is called mathematical reasoning. Mathematical reasoning is an ability to solve mathematics problems. There are five various types of mathematical reasoning, such that; 1) Algebraic reasoning, 2) Proportional reasoning, 3) Statistical reasoning, 4) Geometrical reasoning, 5) Probabilistic reasoning. Which all of those component are in learning school mathematics. When students are learning mathematics, teacher must be direct students to build their reasoning.

Walle [15] makes a conclusion that algebraic reasoning is ability to representing, generalizing and formalizing pattern and regularity in all aspect of mathematics. There are levels within learning algebra. Learning school mathematics is not always use abstract symbol, because teachers must be developing mathematics reasoning gradually. Lesh, Post, and Behr [16] claimed that proportional reasoning is ability to compare different comparison and mental ability to store and process the information pieces by using sensory. So, when students learn about ratio and they can compare all of different comparison, its mean students have a proportional reasoning. Sceaffer [17] stated that statistical reasoning is ability to solve mathematics problems related to corporate data, sampling and experimentation, anticipating patterns and statistical inference. Then Jeanette [18] says that “geometrical reasoning is the process defining and deducing the properties of a geometric entity using the intrinsic properties of that entity, its relationships with other geometric entities and the rules of inference that kind such properties together in geometric space”. The last of various types of mathematical reasoning is probabilistic reasoning. Have the same principle with statistical reasoning, probabilistic reasoning is ability to see pattern in data.

V. RELATION BETWEEN MATHEMATICS REASONING, HOTS AND STUDENTS CHARACTER

Students who give non routine mathematical problems in continue ways; will give the effect of improved thinking skill. Thinking improvement is characterized by the reason ability or gives reasons over the settlement they earn. This ability is called mathematics reasoning. Mathematics reasoning needs critical and creative thinking skills, which is both an indicator of higher order thinking skills. So it is understood that reasoning, critical and creative thinking skills are indicators of Higher Order Thinking Skill such as formulated by the Bloom that Higher Order Thinking Skills is a process that involves mental, such as classification, induction, deduction, and reasoning.

Thus, it is known that in order to improve high order thinking skills required learning mathematics with mathematical reasoning. But note that mathematical reasoning include analyze, differentiate, simplify, presenting and illustrating with accompanying reasons. And this would not be realized in learning just a few times, but it takes a long time to let those skills appear in students. The exposure of previously known that high level thinking skills can foster student’s character, it is seen from the student's persistence in solving mathematical problems presented by the teacher. To solve mathematical problems in diverse, it is not possible for students to find an alternative solution in short time, which could indicate towards a critical and creative. In the face of diverse mathematical problems, the non routine, students need quite a long time so that it will appear in the process traits of character that leads to students as thorough, diligent, sensitive, honesty, tolerance, caring, democratic, disciplined, hard working, independent, high curiosity, never give up, critical and creative.

VI. CONCLUSION

Higher Order Thinking Skills is a process that involves mental, such as classification, induction, deduction, and reasoning. And if we drawn in mathematics there are five various types of mathematical reasoning, such that; 1) Algebraic reasoning, 2) Proportional reasoning, 3) Statistical reasoning, 4) Geometrical reasoning, 5) Probabilistic reasoning. With mathematical reasoning, teachers can provide space for students to think logically in understanding mathematics concepts and consider all the possibilities that exist to solve problems. In the process of finding the solution of this problem, students will require unusual thinking skills are often referred to as higher order thinking skills. Improved way of thinking in the process of mathematical problem solving can build performance and moral student's characters such as discipline, honest, responsible; never give up etc. Because there are six pillars of character such that, 1) Trust, 2) Respect, 3) Responsibility, 4) Fairness, 5) Caring and 6) Citizenship. When learning mathematics that uses mathematical reasoning as one of focus learning can increasing higher order thinking skill. This can be achieved when in learning process; teachers provide opportunities for students to explore their ability. Then, with non routine problems, students will be used to looking for creative solutions, critically analyze, unyielding seek a proper, honest and tolerance in the difference solutions. And teacher's belief when provide an opportunity for their students can affect their moral characters, because students will find that their mathematics teacher is an open-hearted person. So, students will apply these characters in their life.

***Abstract*—**Problem-based Learning (PBL) is one of recommended learning models in implementation of curriculum 2013. PBL provides opportunities for students to construct knowledge, and enhance their thinking skills through the filling of a problem as the starting point of learning process. Problems in PBL requires students to regain access to prior knowledge that lead students to think deeply. Thinking is infused in PBL when students plan, generate hypothesis, employ multiple perspective, and work through facts and ideas systematically. Problem resolution also involves logical and critical analysis, use analogies and divergent thinking, and creative integration and synthesis. Thinking Activities are needed by students, especially for understanding difficult math materials. One of math material that need student's thinking is calculus. It consist of limit, derivative, and integral of function. Not only a lot of students that have difficulties to learn calculus, but also teachers. They have difficulties in how to teach this material. Therefore, PBL is the most suitable method that can be an alternative to teach calculus. In conclusion, PBL activities in the classroom will foster student's higher-order thinking skill.

Keywords: *fostering, higher-order thinking skill, problem-based learning, problem, calculus*

I. INTRODUCTION

Inovation in education still held in every year to improve quality of learning activity. Improvement of learning quality purposed to solve all problems that faced, include Mathematics learning problems. One of inovation in education that had been done by government is evaluation of curriculum.

In 2013, Indonesian government decide new curriculum named curriculum 2013 for elementary and secondary school. Implementation of that curriculum can be seen in learning procces in the classroom. Learning procces of schools helds in interactive, inspirative, interesting, challenging, and motivated students to be active and give oppurtunities for their innovation,creativity, independece through their talent, interest, physically and psychology [11]. Paradigm that used in learning procces is constructivism [16]. So that learning models that used in learning procces based on constructivism paradigm.

Implementation of curriculum 2013 still has many problems. Most of teachers in indonesia have difficulties in impelementation curriculum 2013 [16]. The big problem that face is the lack of teacher understanding about the new curriculum [17]. In the other hand, learning quality in the classroom effects in improvement of student's thinking skill. Teacher as a designer must provide learning atmosphere that can be support improvement of sudents' thinking skill. Ideally, all students are provided high-quality instruction that offer the opportunity to learn the knowledge and skill [7]. In constructivist class, a teacher does not teach how to answer the questions, but presentated problem and encouraging students to find out their strategy in solve the problems.

According to Vygotsky, thinking skill growth from lower to high level. Learning material should be used as a tool to train student's thinking skill, not as a purpose [19]. Beside that, learning not only as rehearsing information and formulas/equation, but also how to use that information and knowledge to sharp the thinking skill. The learning environment should encourage students to engage in higher-order thinking activities [19]. Teachers need to move away from an over-emphasis on content mastery and adopt pedagogies that enable the development of thinking processes [15]. To foster student's higher-level thinking, teachers must possess not only in-depth subject matter knowledge in the field they are specializing in, but also good pedagogical knowledge on how to develop student's higher-order thinking –

both in the context of the subject matter they are dealing with and as a general skill [2]. Pedagogical knowledge include learning models based on the purpose in curriculum.

One of learning model that recommended in implementation of curriculum 2013 is Problem-based learning [16]; [10]. Problem-based learning (PBL) is learning that use problem as starting point of learning procces [21]. “Problem-based learning has been shown to actively engage students in relevant learning experiences” [1]. Student’s activities in problems-based learning, can help them to build their thinking skills and problem solving. effort to encourage student’s higher-order thinking skill that have positive effect in increasing motivation and achievement [4]. In short, problems that pose in learning process can help students to construct their knowledge and find out the concept through problem solving process.

Students need thinking activities to understanding the difficult learning material in mathematics. One of the difficult material is calculus [20]; [3]. Not only a lot of students that have difficulties to learn calculus, but also teachers. They have difficulties in how to teach this material. To solve the problems, learning by using PBL model can be used as an alternative. Many finding of researches was suggested teachers to use PBL in learning mathematics to improve student’s thinking skill. PBL in calculus course improve student’s critical thinking, evaluative and judgment/making decision [13]; [9]. Therefore, adopting PBL method in learning process, teacher can create a number of creative thinkers, critical decision makers, problem solvers which is very much needed for the competitive world.

II. LITERATURE REVIEW

A. Problem-based Learning

Problem-based learning (PBL) is a student-centered approach that organizes curriculum and instruction around carefully crafted “ill-structured” and real-world problem situations [1]. PBL focus on problem use as starting point in learning process [21]. Problem-based instruction describes a learning environment where problems drive the learning. That is, learning begins with a problem to be solved, and the problem is posed such a way that students need to gain new knowledge and skill before they can solve the problem[18]. PBL is recognized as a progressive active-learning and learner-centered approach where unstructured problems (real-world or simulated complex problems) are used as a starting point and anchor for the learning process [21]. It can be conclude that problem-based learning (PBL) is learning model that student-centered and use contextual, complex, ill-structured problems as starting point learning process. PBL process not only oriented in finding solution of the problems, but also problem solving process it self and help them to find the concept.

PBL activities in the classroom involve design of problems and organize of students. Every step of PBL required students be active in that activity. Problem-based learning (PBL) in the classroom includes the following steps. Tan [22] suggest five steps: (1) meeting the problem; (2) problem analysis and learning issues; (3) discovery and reporting; (4) solution presentation and reflection; and (5) overview integration and evaluation. Arends and Kilcher [1] suggest five steps: (1) orient students to the problem; (2) organize students for study; (3) assist independent and group; (4) develop and present artifacts and exhibits; and (5) analyze and evaluate the solving process. Beside that, Eggen and Kauchak [6] suggest four steps: (1) review and present the problems; (2) define strategy; (3) implement the strategy; and (4) examine and evaluate solution. According to some opinion above, we can see that PBL activities in the classroom include: (1) present the problems; (2) organize students for study; (3) identification and formulation the problems; (4) investigate and problem solving; (5) solution presentation presentasi; and (6) evaluate and making conclusion.

Teacher’s roles in PBL are design the problems, facilitate, and mediate students in learning process. Teachers do not give subject material but motivated and facilitated students by giving problems. In problem-based learning, complex and real-world problems are used to motivate students to identify and research the concepts and principles they need to know to work through those problems [5]. In PBL, students are given the opportunity to find knowledge for themselves and to deliberate with other. They then refine and restructure their own knowledge with new knowledge and experiences. Therefore PBL in the classroom is not only about infusing problems into the class but also about creating opportunities for students to construct knowledge themselves. Fig. 1 shows shift of learning paradigm from traditional model that focused on learning material to be learning that focused on problems by using problem-based learning (PBL).

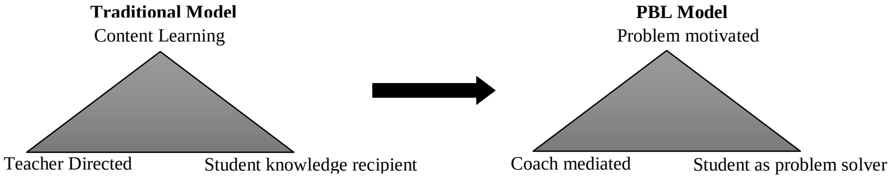

FIGURE 1. SIFT OF LEARNING PARADIGM FROM TRADITIONAL TO BE PBL

Paradigm that used in PBL appropriate with curriculum 2013. There are 14 points suggested in learning process based on this curriculum. Several of learning process that suggest in that curriculum accommodate in PBL. there are learning that from students be informed about concept, to be students to find out, from teacher as the only one learning source to be learning with many sources, from learning based content to be learning based competence, and from learning that suggest one solution/answer to be multi solution [11].

B. Facilitating Higher-order Thinking Skill in PBL Process

Here are techniques to foster student's higher-order thinking skills through learning activities in the classroom. These techniques are related with teaching strategies. Musfiqi and Jailani advise that to improve the higher-order thinking skills (HOTS) of students, the teacher's role as facilitator should be noticed [14]. Moreover, Protheroe [8] suggested that a mathematics classroom must do the following things to achieve an effective environment for higher-order thinking: (1) actively engage in doing mathematics; (2) solve challenging problems; (3) make interdisciplinary connections; (4) share mathematical ideas; (5) use multiple representations to communicate mathematical ideas; (6) use manipulative and other tools. Beside that, Upon studying the effects of varying instruction for high school math and science students, Miri, David, and Uri [12] proposed the following three teaching strategies for generating higher-order thinking skills: (1) present real-world cases–encourage students to cope with relevant situations; (2) direct class discussions related to a concept/phenomenon or a problem–encourage students to ask questions and present their own solutions; and (3) guide short inquiry-type experiments in groups–encourage students to learn in cooperation.

Thinking is infused in PBL when students plan, generate hypothesis, employ multiple perspective, and work through facts and ideas systematically. Problem resolution also involves logical and critical analysis, use analogies and divergent thinking, and creative integration and synthesis. One of strategy that can be used by teachers in PBL is the questioning method. Questions aim to help students through each step in the PBL activity. Many researchers have proposed using probing techniques or questioning methods to enhance thinking in students. Asking higher-order questions has values in helping students to develop their thinking skills Wetzel [8] proposes using the following examples as questions that probe the individual toward higher understanding: (1) what additional information do you need to solve the problem?; (2) how does the data relate to your findings?; (3) how does the evidence support your conclusions?; (4) what would you need to do to determine if this solution is true?; (5) how can you compare this with other problems?. These questions can be given from the beginning until the end of learning process. Table 1 show the list of the questions that can be used to facilitate student's thinking skill in PBL activities.

TABLE 1. QUESTIONS LIST TO FACILITATE HOTS IN PBL ACTIVITIES

PBL Activities	Question
Identification and formulation the problems	• What the meaning of limit on that problem? • What being approximate? • Is the value of f(x) around x = c can be define? • Why the value of f(x) at x = c does not exist? • What are the differences tangent line and secant line? • What additional information do you need to solve the problem?
Investigate and problem solving	• Is the limit of function can be define by using method…? • Why limit of that function can not be define by method…? • Is the problem can be solving by using method…? • Is the other ways more effective?
Evaluate and making conclusion	• How about the limit of function… if the value of x is change with approximate with….? • Write two or more problem that can be define by using our concepts. • What would you need to do to determine if this solution is true? • How can you compare this with other problems?

III. CONCLUSSION

Based on the description above, it can be concluded that PBL activities in learning calculus class will foster student's higher-order thinking skill. Beside that, to be more effective in PBL activities, teacher's role as a facilitator should be noticed In addition, the use of PBL in teaching calculus must be supported with these kinds of problems presented in each of the learning process.

The Student' Models For The Meaning And Procedure Of Multiply Two Fractions

Hongki Julie[1]

[1]Mathematics Education Department, Sanata Dharma University

hongkijulie@yahoo.co.id

Abstract—Lortie-Forgues, Tian and Siegel (2015) suggests that students' understanding of the fractions is very important in the study of mathematics further and are also used in many professions, but according to Lortie-Forgues, Tian and Siegle (2015) and MA (1999), many students have great difficulty in understanding it. Furthermore, according to Ma (1999), the difficulty is not only the difficulties experienced by students in learning fractions, but also the difficulties experienced teachers to teach the concept of fraction. It was felt by teacher at one of the private elementary school in Yogyakarta, especially in teaching multiplication on fraction. The goals of this study were (1) finding the student'model that could be constructed when they learnend about the meaning and procedure of multiplication between an integer and a fraction, and (2) finding the student'model that could be constructed when they learnend about the meaning and procedure of multiplication of two fractions. There were two contexts used by the researchers in this study that is buying the ribbon and giving oranges. Lesson plan created by the researcher were for students of grade five. There were six models of multiplication between an integer and a fraction that could be constructed by students using that context. There were four models of multiplication of two fractions that could be constructed by students using that context. This type of research used by the researchers in this study was the design research developed by Gravemeijer and Cobb. According Gravemeijer and Cobb (in Akker, Gravemeijer, McKeney, and Nieveen, 2006) there are three phases in the research development, namely (1) the preparation of the trial design, (2) test the design, and (3) the retrospective analysis.

Key Words: *the multiplication of fractions, realistic mathematics education (RME), and design research.*

I. INTRODUCTION

In 2013 and 2014, the researcher developed some context and sequence of learning that can be used to teach the fractional multiplication in grade five of the elementary school. From the experience of two years, the researcher wanted to try to develop another context that will be used to teach the multiplication of the fraction in grade five of the elementary school. In this year, the researcher had the opportunity to develop and provide context about buying the ribbon, and giving oranges. The researcher also got the opportunity to pilot the lesson plan in one class on grade five in a private elementary school in Yogyakarta. In this paper, the researcher would present the student'models that could be built by students when problems were built with the context given to students.

Lortie-Forgues, Tian and Siegel (2015) suggests that students' understanding of the fractions is very important in the study of mathematics further and are also used in many professions, but according to Lortie-Forgues, Tian and Siegle (2015) and MA (1999), many students have great difficulty in understanding it. Furthermore, according to Ma (1999), the difficulty is not only the difficulties experienced by students in learning fractions, but also the difficulties experienced teachers to teach the concept of fraction. There were several studies that have been done related to fractions which explains why fractions into one material that is difficult to understand by students, namely:

1. According to Lamon (2001, in Ayunika, 2012), the development of understanding of the meaning of fractions in the teaching-learning process was a complex process because the concept of fraction had a

number of interpretations, namely (1) fraction as a part of the whole, (2) fraction as the result of a measurement, (3) fraction as an operator, (4) fraction as a quotient, and (5) fraction as a ratio.
2. According to Ross and Case (1999 in Shanty, 2011), on the process of learning fractions, teachers often emphasize on how to do the operation procedure than on the meaning of the operation.
3. Stafylidou dan Vosniadou (2004 in in Shanty, 2011) states that one of the reasons why the idea of mathematical fractions are systematically misinterpreted by students is an inconsistency with the principles of arithmetic used in operations involving natural numbers. For example in the operation of multiplication of natural numbers, if the two natural numbers multiplied, then the multiplicative result is a natural number greater than or equal to two natural numbers are multiplied. It was not always the case if the two fractions multiplied.
4. According Streefland (1991), in many textbooks the instruction of fractions is characterized by:
   a. Towards the concept of fraction.
   b. There are not meaningful contexts both as sources and domains for the application of fractions.
   c. The isolated use of models and patterns, which never extends to serve the process of algorithmization or mathematization.
   d. There are not connections with mathematically domains, such as decimal fractions, ratios, scale, and percentages (Vergnaud, 1981).
   e. Towards the algorithms.

There were two questions that will answer in this paper, namely (1) what were the student'model that could be constructed when they learnend about the meaning and procedure of multiplication between an integer and a fraction? and (2) what were the student'model that could be constructed when they learnend about the meaning and procedure of multiplication of two fractions?

II. THEORETICAL FRAMEWORK

The philosophy of RME was mathematics as a human activity, which means that the learning process of mathematics first of all should not be connected with mathematics as a deductive system that was well organized and formal, but it should be connected with mathematics as a human activity (Freudenthal, 1971, 1973, in Gravemeijer, 1994). If the mathematics which was learned by the student was connected with a formal deductive system, then the student will view that mathematics was resulted by the human thinking; it was an abstract and was not related to real-life. So, they will think that they could not find mathematics and using mathematics in their life. Learning mathematics should be able to make the students thought that there was mathematics in human activities, and it was be used by them in real life.

There are four main principles in the RME (Gravemeijer, 1991 and 1994, Treffers, 1991, and Julie, 2014), namely:

1. Guided reinvention;

According to this principle, students were given the opportunity to be able to reinvention both concepts and procedures in mathematics, "like" the mathematicians to find it. In the reinvention process was done by the students, in addition there was the teacher guidance, there needs to be a student communication, and there was a negotiation process between one student and other students. The communication and negotiation process between one student and other students were intended to develop students' findings gradually until the students can achieve the mathematics formal knowledge.

2. The progressive mathematizing;

In RME, students learned to construct a formal mathematical knowledge through to solve the contextual problem series. In RME, this process is known as the mathematizing process. Students were expected to experience the development in every stage of problem solving from one problem to other problems. This development was happen in the translating problem and in the retranslating solution of the problem. The problem solving process evolved from informal strategies to more formal procedures. In the end, the solution for a kind of the problem becomes routine. In other words, the solution procedure on the similar problem can be simplified further and formalized through the problem series, so that at the end, a formal procedure can be found by students. Through this learning process, a formal mathematical knowledge can be reconstructed by themselves. This process is illustrated in figure 1. In the RME, this process is called a progressive mathematization.

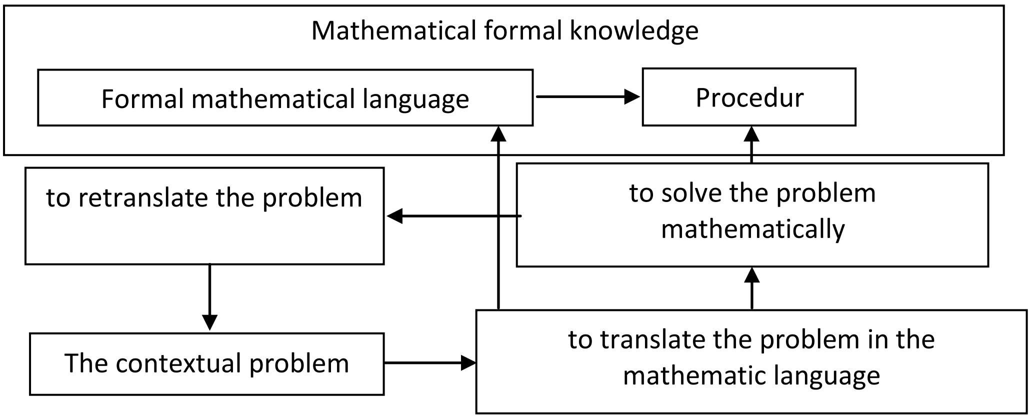

Figure 1: The reinvention process through the progressive mathematization process

3. Didactical phenomenology;

The students were given the opportunity to explore phenomena or situation series that can make students experience the process of establishing a formal mathematical knowledge in a sustainable manner. The purposes of the investigation of the phenomenon by students were to investigate the circumstances that approach to the particular phenomenon, and the results of the investigation can be generalized to generate solution procedures, so it would develop the formal mathematical knowledge.

4. Self-developed models.

In RME, models were interpreted as a representation of translating problems into the mathematics language and problem solving in the problem solving stages. A model in RME may involve a model of a situation, schematics, descriptions, or a way to express an idea or ideas. The modeling process by students played the role as a bridge between the informal and formal mathematical knowledge. In RME, the models must be built by themselves as a result of the exploration of the phenomenon by the students and the basis for forming a formal mathematical knowledge. It means that students should be given the opportunity to build models when the problem solving process was occured.

When teacher seek to build the formal mathematical knowledge of students, teacher need to do with the bottom-up approach. First, a model was related to real life activities, and it was called the **situational model**. After that, a model was a model of the specific context, and the model obtained in this way is termed **model of**. Then, the model was generalized to many similar situations, and the model was constructed in this way is termed the **model for**. At the end, the model becomes something truly lies within students, and can be used as a basis to achieve a formal knowledge of mathematics and it was called the **formal model**.

III. RESEARCH METHODOLOGY

The approach used to develop the students' learning materials and the teacher guide in this research activity was RME. This type of research that was used by the researcher in this study was the design research with three cycles. Things that were presented in this paper what was done by the researcher and what comes out of the third cycle. The data analysis was conducted by video data and the student's work. The steps undertaken by the researcher followed the phases in the development research were developed by Gravemeijer and Cobb.

IV. RESULTS

The research results presented in this paper were limited by the researcher on the third cycle. The aims of the design that was made by the researcher were that students could know about (1) the meaning and the procedure of the multiplicaton between an integer and a fraction, and (2) the meaning of multiplication of two fractions and the fractional multiplictation procedure. Before students experienced learning process designed by the researcher, students have learned about fractions in grade four, namely (1) the meaning of fractions, (2) the ordering of fractions, (3) the simplfying of fractions, and (4) the additing and subtracting of fractions. The problems were given to students inspired by the problems that exist in the book that written by Fosnot, and Dolk (2002) and the teacher' idea who taught the students in grade five.

Here was presented problems that were given to students, and the student'model about (1) the meaning and the procedure of the multiplicaton between an integer and a fraction, and (2) the meaning of multiplication of two fractions:

1. **The problem was given to students:**
   Kiki needed 3 pieces of ribbon for the gift decoration.
   The length of each ribbon was needed Kiki is $\frac{2}{3}$ meter.
   To fulfill the needs of a ribbon, Kiki would purchase the ribbon.
   How many meters of ribbon were to be purchased by Kiki?
   The Student'models:
   a. Students made the following picture:

   Thus, the length of the ribbon that needed to be purchased by Kiki was 2 meters.

   b. Students make the following picture:

   Students then made the following calculations: $\frac{2}{3}+\frac{2}{3}+\frac{2}{3}=\frac{2+2+2}{3}=\frac{6}{3}=2$. This step was vertical mathematizing.
   Thus, the length of the ribbon that needed to be purchased by Kiki was 2 meters. This step was hisontal mathematizing.

   c. Students made the following picture:

   Students then made the following calculations: $\frac{2}{3}+\frac{2}{3}+\frac{2}{3}=3\times\frac{2}{3}=\frac{3\times 2}{3}=\frac{6}{3}=2$. This step was wertical mathematizing.
   Thus, the length of the ribbon that needed to be purchased by Kiki was 2 meters. This step was horisontal mathematizing.

   d. Students made the following calculations: $\frac{2}{3}+\frac{2}{3}+\frac{2}{3}=\frac{2+2+2}{3}=\frac{6}{3}=2$. This step was wertical mathematizing.

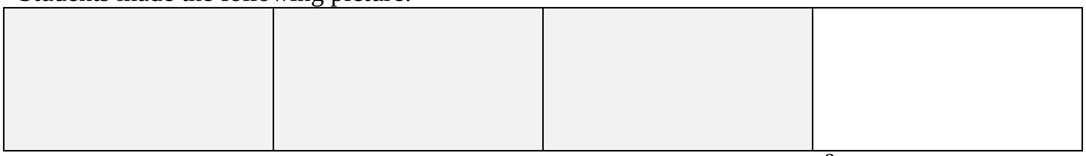
   e. Students made the following calculations: $\frac{2}{3}+\frac{2}{3}+\frac{2}{3}=3\times\frac{2}{3}=\frac{3\times 2}{3}=\frac{6}{3}=2$. This step was wertical mathematizing.

   f. Students made the following calculations: $3\times\frac{2}{3}=\frac{3\times 2}{3}=\frac{6}{3}=2$. This step was wertical mathematizing.

2. **The problem was given to students:**
   Gofil had $\frac{3}{4}$ kg of oranges.
   Gofil gave half part of oranges owned to Berto.
   How many kg of oranges would be given by Gofil to Berto?
   The Student'models:

horisontal mathematizing

a. Students made the following picture:

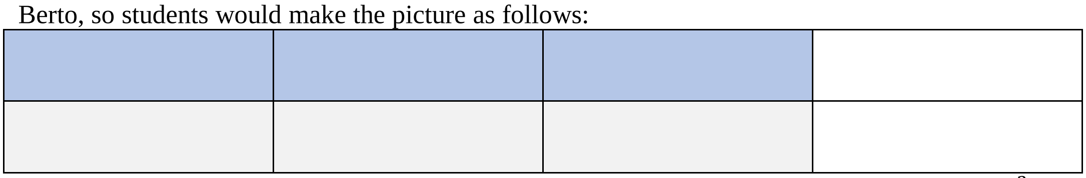


The gray shaded area was the heavy of the orange that owned by Gofil, i.e. $\frac{3}{4}$ kg.

horisontal mathematizing

Then, students shore the Gofil' orange into two equal parts. Students would get half part of the Gofil'orange. Students would make the following picture:

Then, students shaded with different colour to show the half part of the Gofil's orange given to Berto, so students would make the picture as follows:

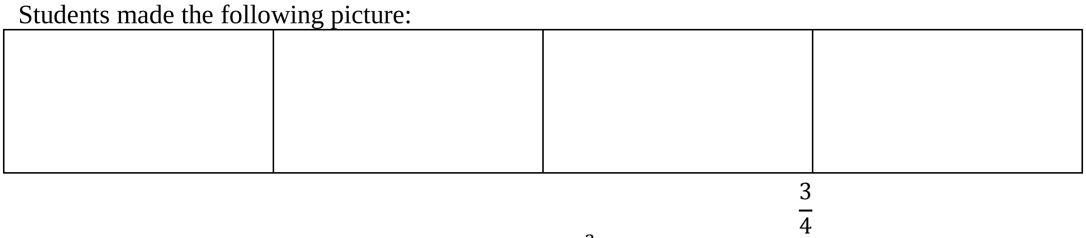


vertical mathematizing

1) The blue shade indicated the area of the Gofil'orange given to Berto, that is equal to $\frac{3}{8}$ kg. Because there were 3 blue shade parts of 8 parts of a whole.
2) The blue shade indicated the area of the Gofil'orange given to Berto, that is equal to $\frac{1}{2}$ part of $\frac{3}{4} = \frac{3}{8}$ kg. Because there were 3 blue shade parts of 8 parts of a whole.

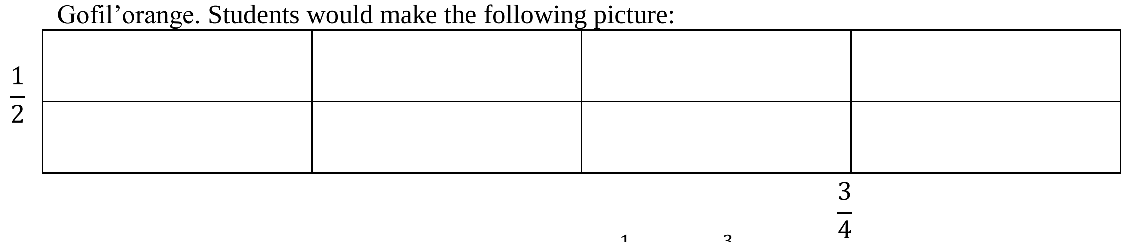
horisontal mathematizing

b. Students made the following picture:



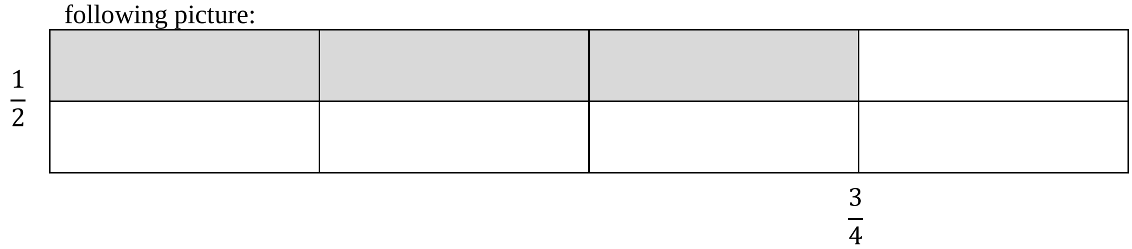
Students annotate the boundary area that showed $\frac{3}{4}$, so the weight of the Gofil' orange was represented by the left area of the boundary.

Then, students shore the Gofil' orange into two equal parts. Students would get half part of the Gofil'orange. Students would make the following picture:



Students annotate the boundary area that showed $\frac{1}{2}$ part of $\frac{3}{4}$ kg, so half of the Gofil 'orange weight was represented by the upper area of the boundary.

Then, students shaded to indicate the area of Gofil'orange given to Berto, as shown in the following picture:

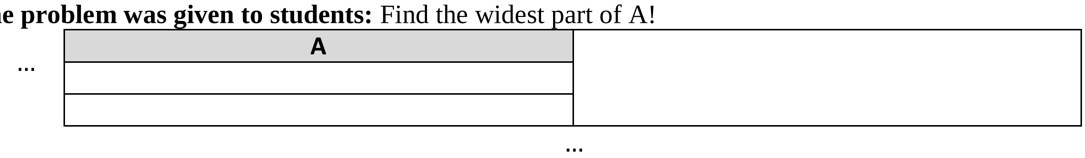


ISBN 978-602-74529-0-9

vertical mathematizing

1) The gray shade indicated the areas of Gofil'orange given to Berto, that is equal to $\frac{3}{8}$ kg. Because there were three blue shade parts of eight parts of a whole.
2) The gray shade indicated the areas of Gofil'orange given to Berto, that is equal to $\frac{1}{2}$ part of $\frac{3}{4} = \frac{3}{8}$ kg. Because there were 3 blue shade parts of 8 parts of a whole.

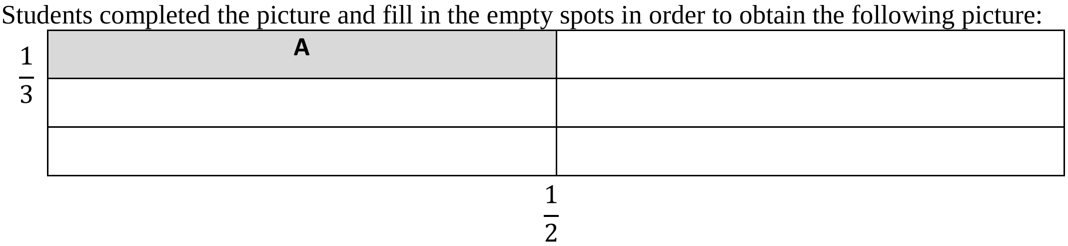
3. **The problem was given to students:** Find the widest part of A!



The Student'models:

horisontal mathematizing

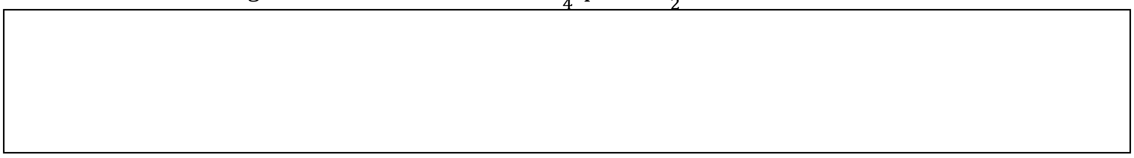
a. Students completed the picture and fill in the empty spots in order to obtain the following picture:



vertical mathematizing

b. Then, students made calculation to find the widest part of A, i. e.:
   1) Students calculated, the widest part of A = $\frac{1}{3}$ part of $\frac{1}{2} = \frac{1}{6}$.
      Because there was one gray shade part of six parts of a whole.
   2) Students calculated, the widest part of A = $\frac{1}{3}$ part of $\frac{1}{2} = \frac{1}{3} \times \frac{1}{2} = \frac{1 \times 1}{3 \times 2} = \frac{1}{6}$.
   3) Students calculated, the widest part of A = $\frac{1}{3} \times \frac{1}{2} = \frac{1 \times 1}{3 \times 2} = \frac{1}{6}$.

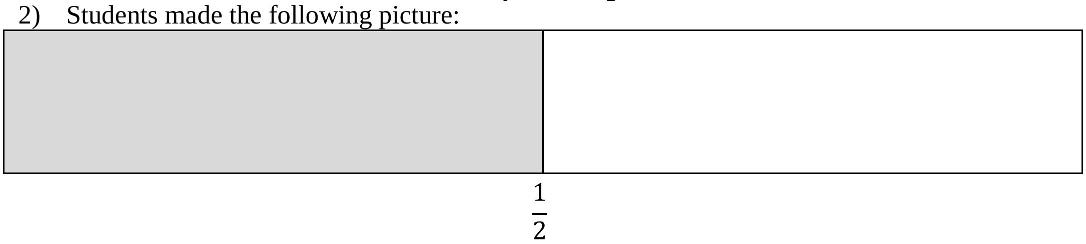
4. **The problem was given to students:**
   Use the follow rectangle to illustrate the statement $\frac{1}{4}$ part of $\frac{1}{2}$ and calculate the results.



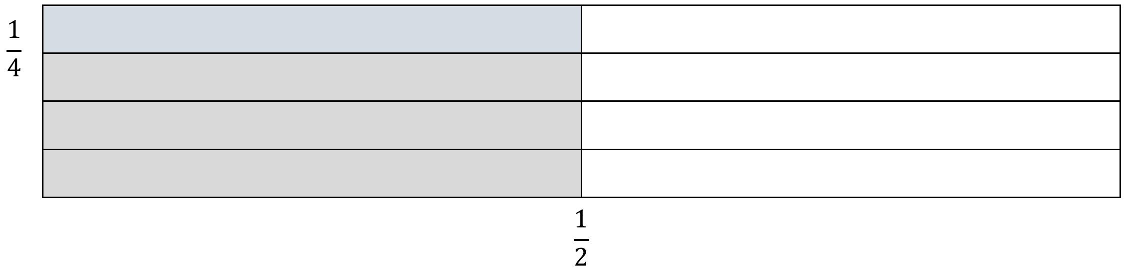
The Student'models:

a. The possible answers were made by the student to describe $\frac{1}{4}$ part of $\frac{1}{2}$. This step was horisontal mathematizing.
   1) Students made the following picture:

   Students stated that the shaded area was $\frac{1}{4}$ part of $\frac{1}{2}$.
   2) Students made the following picture:

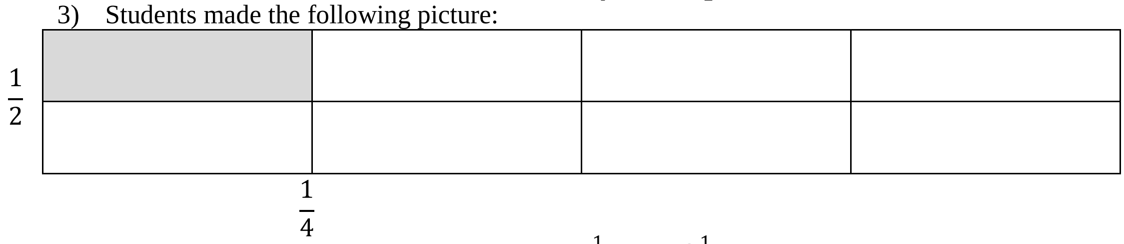


Students stated that the gray area shaded was $\frac{1}{2}$.
After that, the students subdivide the rectangle to obtain the following picture:



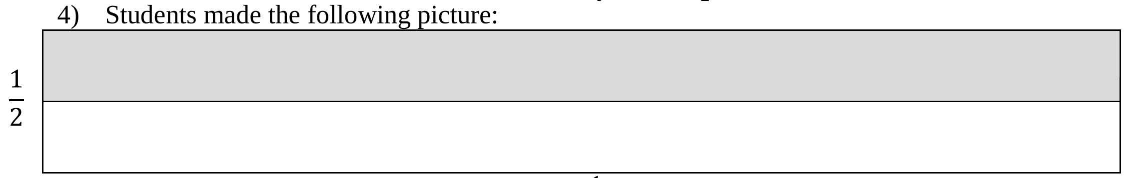
Students stated that the blue shaded area was $\frac{1}{4}$ part of $\frac{1}{2}$.

3) Students made the following picture:

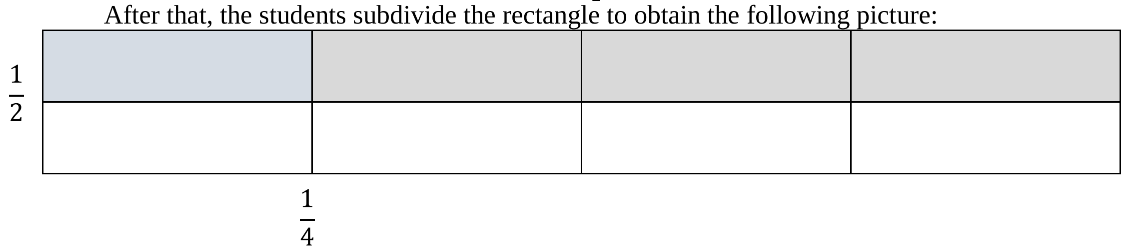


Students stated that the gray shaded area was $\frac{1}{4}$ part of $\frac{1}{2}$.

4) Students made the following picture:



Students stated that the gray shaded area was $\frac{1}{2}$.
After that, the students subdivide the rectangle to obtain the following picture:



Students stated that the blue shaded area was $\frac{1}{4}$ part of $\frac{1}{2}$.

b. Then, to calculate the amount of $\frac{1}{4}$ part of $\frac{1}{2}$, the possibility undertaken by students were as follows: (this step was vertical mathematizing)
   1) Studensts answered $\frac{1}{4}$ part of $\frac{1}{2} = \frac{1}{8}$. Because there was one gray shade parts of 8 parts of a whole.
   2) Students calculated that $\frac{1}{4}$ part of $\frac{1}{2} = \frac{1}{4} \times \frac{1}{2} = \frac{1 \times 1}{4 \times 2} = \frac{1}{8}$.
   3) Students calculated that $\frac{1}{4} \times \frac{1}{2} = \frac{1 \times 1}{4 \times 2} = \frac{1}{8}$.

5. **The problem was given to students:** calculate the follow multiplication $5 \times \frac{3}{7}$.
   The Student'models:

vertical mathematizing
   a. $5 \times \frac{3}{7} = \frac{3}{7} + \frac{3}{7} + \frac{3}{7} + \frac{3}{7} + \frac{3}{7} = \frac{3+3+3+3+3}{7} = \frac{15}{7} = 2\frac{1}{7}$.
   b. $5 \times \frac{3}{7} = \frac{5 \times 3}{7} = \frac{15}{7} = 2\frac{1}{7}$.

6. **The problem was given to students:** calculate the follow multiplication $\frac{5}{6} \times \frac{12}{15}$
   The Student'models:

vertical mathematizing
   a. $\frac{5}{6} \times \frac{12}{15} = \frac{5 \times 12}{6 \times 15} = \frac{60:30}{90:30} = \frac{2}{3}$.
   b. $\frac{5}{6} \times \frac{12}{15} = \frac{5}{6} \times \frac{4}{5} = \frac{5 \times 4}{6 \times 5} = \frac{20:10}{30:10} = \frac{2}{3}$.

V. CONCLUSIONS

The student learning materials has been tried out on students in the 5th grade at a private elementary school in Yogyakarta. The results of the trial were as follows:

1. Kiki problem could lead students to develop the situational model on the meaning of multiplying an integer by a fraction and on the calculation of multiplying an integer by a fraction.
2. Gofil' orange problem could lead students to develop the situational model on the meaning of multiplying two fractions and the calculating two fractions.
3. The problem about calculating $5 \times \frac{3}{7}$ could lead students to develop the formal model on the meaning of multiplying an integer by a fraction and on the calculation of multiplying an integer by a fraction.
4. Problem (a) seek the widest part, (b) describe and calculate the results of the $\frac{1}{4}$ part of $\frac{1}{2}$, and (c) calculating $\frac{5}{6} \times \frac{12}{15}$ could lead students to develop the situational model on the meaning of multiplying an integer by a fraction and on the calculation of multiplying an integer by a fraction.
5. The context of the Kiki' ribbon and the Gofil'orange could help students to construct about (a) the meaning and the procedure of multiplication of an integer and a fraction, and (b) the meaning and the procedure of multiplication of two fractions.

Hypnoteaching Method to Foster Self - Belief of Primary School Students in Learning Math

Imaludin Agus[1], Ayu Arfiana[2]

[1,2] Yogyakarta State University, Postgraduate Programme of Mathematics Education
imal.udin@yahoo.co.id

Abstract**—** The aim of writing this article is to examine theoretically related to the use of hypnoteaching method in growing self-belief of primary school students in mathematics Self-belief is one of important affective aspects that human has in living and dealing with challenge. Self-belief can encourage confidence, interest, motivation and optimism in everyone. It implicates for people's success in reaching their desire. In the process of mathematics learning in the classroom, self-belief becomes a connection for establishing a student's knowledge. However, to cultivate the students' self-belief in the mathematics learning is not easy, because the students' mind sets negative thinking or pessimistic of their success in learning mathematics. Therefore, the teacher as an important factor in the learning process should be able to determine an appropriate learning method to minimize the occurrence of these problems. If we browse the characteristic of primary school students, the hypnoteaching learning model could be one of the solutions in order to foster students' self-belief. Hypnoteaching is a learning method that presents the learning material through the subconscious has a great influence on the brain system. In addition, hypnoteaching can also foster students 'self-belief in learning mathematics. Thus, if self-belief has become a part of the students, it will have a positive impact not only in teaching process but also in the daily activities to face global competition.

Keywords: *Hypnoteaching Method, Self-belief,Primary School, Learning Math*

I. INTRODUCTION

Mathematics is one of the subjects that provide a range of benefits in life. However, this rationale does not make mathematics being loved by the students; rather it is a subject that the students afraid of because it is regarded as a lesson that only consist of numbers and formulas. This view makes students' mathematics learning achievement tend to be low. This is supported by the results of PISA 2102 [1] which depicts the students' ability of the Mathematics in Indonesia is on the ranking 64 of the 65 participants. One factor affecting students' achievement is belief or confidence of students in mathematics and mathematics learning.

Self-belief or self-confidence is believed as one of the very important affective aspects for someone to have in living and dealing with something challenging. Self-belief can boost self-confidence, interest, motivation and optimism that implicate to the success in reaching the desired objectives. Similar to mathematics learning, self-confidence has a positive role in order to improve students' achievement. False beliefs, such as making mathematics as a difficult lesson, which filled with numbers and formulas, as well as the abstractness, will have an impact on lower educational achievement. It would be different if the students have a good belief, then implications of course are to the good learning achievement. This is supported by research conducted by Perkins, Adams, Finkelatein & Wieman [2] concluded that there is a positive correlation between students' belief and conceptual learning. Additionally, Eleftheories & Theodosios [3] said that there is a positive correlation between a strong belief and the capabilities and good mathematics performance.

In realizing this, the teacher as the subject of learning designer has a very important role. Teacher should be able to change students' belief of mathematics which said that mathematic is regarded as a difficult subject into an easy mathematics lesson as well as it is beneficial to them. In the process of accommodating this goal, teachers need the ability to select and sort out the proper strategies, approaches, and method in learning mathematics.

In line with the characteristics of elementary school which is contextual math-based learning, then one of the teaching methods that are capable of supporting the learning of mathematics is hypnoteaching method. This method focuses on positive communication uttered by a teacher, who influence the students' subconscious, therefore students will follow what the teachers say and concentrate on learning. By doing so, students will acquire and store knowledge presented by the teacher easily. In addition, Hajar [4] revealed that hypnoteaching has an important role in enhancing confidence in the learning process in the classroom.

Due to the big influence of the students' self-belief to increase their mathematics achievement and the relevance of Hypnoteaching methods to cultivate students' self-belief, then this article will discuss about " Hypnoteaching Method to Foster Self - Belief of Primary School Students in Learning Math".

II. DISCASSION

A. The Characteristic of Mathematics in Elementary School

Mathematics School is not same to pure mathematics studied in university since both have different paradigm. Mathematics school is form of mathematics application concretely that relates to student's life. However, pure mathematics is built on definitions, axioms which become theorems.

Atkinson (Uno) [5] said that mathematics as a structured science, the learning process has to be done systematic, consecutively, and logically depending on student's intellectual development. Having same opinion, Piaget (Uno) [5] explains that primary students will get a concrete mathematics which the proportion depends on the grade, the higher a grade, the more abstract the material.

Ebbutt and Straker (Marsigit, Ilham & Nila) [6] suggest that the mathematics school essence is as (1) an activity of the investigation of pattern or relation (2) an activity of problem solving (3) an investigation activity (4) communication. The essence is nowadays regarded as the alternative to make mathematics as a friendly and pleased subject for students.

Mathematics learning for primary school must be designed interesting that is appropriate for student's cognitive development. Primary school students are still interested in concrete object. Therefore, the mathematics learning process needs an instrument that is media, and model to make what teachers said clear (Heruman,) [7]. According to Piaget (Yusuf) [8], the age of primary school is the end of the children think imaginatively and starts to think logically (relates to the reality). The period is signed by three new abilities, those are clarifying, arrange, or associate the number or symbol. The ability is related to counting like adding, subtracting, multiplying, and dividing.

Finally, we can conclude that mathematics learning process in elementary school has to be done based on concrete things that are around student's life that is appropriate to student's cognitive ability. Therefore, to make the purpose come true, the teachers have to be able to choose and manipulate every media around students learning place to become visual symbol instrument, fact, concept or principle in mathematics.

B. Hypnoteaching Method

Nowadays, many methods, approaches, or strategies the teachers use in learning process to achieve learning purpose. One of the methods that starts to be developed is hypnoteaching.

Hypnoteaching is the development of hypnotism. The word 'hypnoteaching' consists of two syllables, those are hypno and teaching, means as a learning method that uses hypnotism techniques in learning process (Pertiwi) [9]. Nurcahyono (Hajar) [5] suggests that hypnoteaching is an art to communicate by giving power to the students so that the students develop their thinking ways.

Hypnoteaching is a learning method where in the learning process, the teachers use subconscious languages that can grow students interest (Yustisia) [10]. In hypnoteaching, human's mind is divided by three parts that relate each other, those are subconscious mind, critical factor, and conscious mind. The following paragraph is the relation of human's mind part (Pertiwi) [9]:

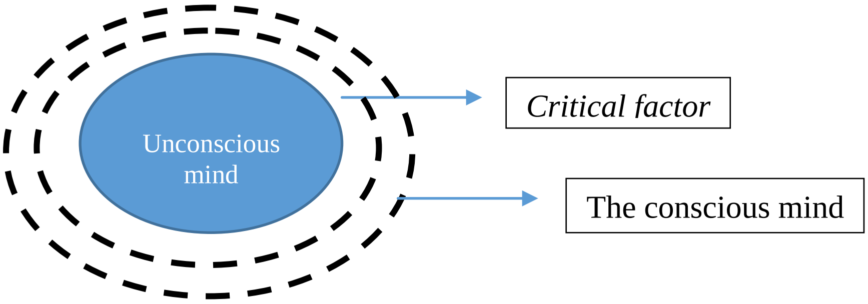

FIGURE 1. BRAIND COMPOSITION

The conscious mind is a mental process which students are in a fully conscious state. In this condition, the students put more emphasis on the process of realistic thinking or according to the ratio of their thinking. The conscious mind has the analysis function to all incoming information, accommodates incoming information and decides on a new piece of information used. The conscious mind has the effect of approximately 10-15% of all aspects of life, such as mindset, attitude, personality, and behavior. Meanwhile, the subconscious mind is a mental process that leads students in a half-conscious thinking process. The subconscious mind is a mind that can accommodate a lot of ideas, thoughts, and actions that the amount is more than the conscious mind. The influence of the subconscious mind in the daily life is about 85-90% that can help people in increasing values, confidence and trust. While the critical factor is the restraint of the conscious mind and the subconscious mind, which acts as a filter of all the information that will be brought into the subconscious. When in a conscious state, the critical factor becomes an obstruction of the incoming information into the subconscious mind. Therefore, with hypnoteaching method teachers help students to undercut critical factor.

Hypnoteaching method provides many benefits in the learning process. Hypnoteaching can provide and create a fun learning environment, in which the negative perception of the teacher and the lesson will change. The atmosphere as this will enable the student to absorb and understand the lessons. The following is a benefit of hypnoteaching (Yustisia) [10]: (1) Learning to be more enjoyable, both students, and teachers; (2) Growing the linkage of students in learning with a variety of creative games that applied by teacher; (3) The teacher becomes more proficient in managing emotions; (4) Fostering a harmonious relationship between teachers and students; (5) Teachers can help students who have difficulties in learning through a personalized approach; (6) Teachers can motivate students through the hypnoteaching game; and (7) The teachers help the students in eliminating bad habits of students.

According to Noer (Yustisia) [10] stages conducted in hypnoteaching are:

1) Self intention and motivation

The successfulness of a person basically is depending on their intention to achieve it. From that intention then motivation of the teacher to applied the hypnoteaching method in class is developed, thus expected to help the students to understand the materials given.

2) Pacing

Pacing are meant to adjust the position, body movement, language, and brainwave in equal manner to the students. Naturally and instinctively, every people should be comfortable and had pleasure to gathering with other people who had something in common. From this comfortable feeling, messages from the teacher are expected to be more easily to be received by the students. The teacher, in this condition are could be: thinking to be as a figure with similar age as the students, using language used by the students, perform movement or mimics that related to the theme discussed in the class, and the teacher can also relate the discussed materials to the daily life of the students.

3) Leading

Leading are expected to direct. Leading are done after the pacing, where the students are already comfortable with the class atmosphere. In this condition, the teacher could be direct the student. So, although in actuality the given material is rather difficult, the students' sub-consciousness is more easily to accept.

4) Giving positive words

This is a supporting step in pacing and leading. The use of positive words is suitable with how the sub-consciousness are work which tend to reject negative words. Positive words given by the teacher are believed to be able improving the students' confidence in receiving the materials given. For example, the teacher is expected to avoid the use of "be quiet", and advised to use "your attention please" instead.

5) Compliment

Reward or punishment are not something wrong to be applied in class. Compliment are reward to improve the self-esteem of a person, and punishment is a penalty or warning given by the teacher when students are deemed to have inappropriate behavior. From the reward, students are expected to be motivated to improve their performance. In other case, punishment is expected to made students avoid inappropriate or norm breaking acts

6) Modelling

This steps are a process to give a role model for example from the teacher to the students by consistent words and behavior. Modelling is applied to develop students' trust to the teacher

7) Mastery of the materials

A teacher should be well prepared to the materials presented in the class and relate it contextual condition in order to help student more easily to understand the respective materials.

Based on these review, it could be concluded that hypnoteaching is an educational method that insists on giving suggestion to the student along the learning process, where the teacher using a certain "subconscious language" that expected to develop interest in students that led to improvement of their way of thinking.

C. Self-Belief

Self-belief are often defined as internal factor in a person which affect their attitude in daily life. According to Raymond [11], trust in mathematics are defined as "personal judgments about mathematics formulated from experiences in math". Similar thing is stated by Eleftheories and Theodosios [3] "We will use the term "beliefs" in the meaning of personal judgments and views, which constitute one's subjective knowledge, which does not need formal justification".

Self-belief are included as affective aspect. This aspect important role in mathematics and mathematical education. This was stated by McLeod (Maab and schlogman) [12] that in mathematical education affective aspect are including emotional, behavior, and belief. This aspect is given in order to improve stability and cognitive elements. Kloosterm (Kislenko) [13] stated that belief is a something that are known and perceived by the students as effect of learning math. In another view, belief is related to student's effort to prepare in learning math.

Maab and Schlogman [12] stated that self-belief of the student became interesting issue to explored, because self-belief has tightly related to math or math education. Self-belief has positive effect to the improvement of students' achievement. This is in line with the Maab and Schlogman's opinion that in math education, self-belief became an important predictor in teaching. Beside, self-belief also very important as foundation of the student in math studies.

The research of Perkins, Adams, Finkelatein, and Wieman [2] concluded that there is positive correlation between the self-belief of the student with conceptual learning and stated that self-belief was a factor that affect the learning of the student, which have resulted in successfulness in study and remarkable achievements. Along with it, research of Eleftheories and Theodosios [3] showed that there is also positive correlation between strong confidence with good capabilities and performance in math.

Based on the review of several opinion and two research result, it can be concluded that self-belief of the student to math is a factor that can lead the students to their best achievement, especially in math and math studies. Therefore, this aspect needs critical attention from the teacher, so that math wouldn't become fearsome for the students. Teacher should become a facilitator in improvement of the student's confidence in learning math, so implicated to the improvement of students' achievement.

D. Hypnoteaching Method in developing Self Belief Student

Math is one of the subject which is full of concept. Concept is defined as abstract idea which became differing characteristic between one object with another. As with the standpoint of Howard (Schunk) [14] which stated that a concept is a real arrangement ore categorical representation which allow people to recognize examples and that which isn't categorical examples. That concepts are could cover concrete objects or abstract ideas. Therefore, abstract idea causing math concept are relatively difficult to be understand and applied in solving problems in daily life. Thus, this became the duty of the teachers in creation of learning that relate math with concrete matters of students' daily life.

Beside creating a concrete learning, teachers also able to use hypnoteaching method to sustain the learning process. Hypnoteaching method is having some advantages, which is : (1) Learning process is became more dynamic and creating conducive interaction between student and teacher; (2) Student are studying based on their interest and talent; (3) Many skills given in hypnoteaching; (4) Variety of earning process; (5) Mastery of the materials by the students are faster and easier; (6) Very active learning process; (7) Students in learning can be intensively observed; (8) The ability of student to imagining and thinking are more noticeable; (9) Students studying in good mood; (10) Students are having high understanding and absorptivity on the lesson and could be memorized in a long time; (11) Student are more focused in the study.

Math learning that adjusted with cognitive level of the students and supported with hypnoteaching learning model which emphasized on giving suggestion to the student. Student could be asked to focus in learning and understand the lesson given. Teacher also could convey positive words to motivated the students in learning. These words could be received by the student's sub-consciousness. Thus, hypnoteaching method could help student to develop self-belief which then giving positive effect to the student's achievement in learning. Self-belief are often defined as internal factor in a person which affect their attitude in daily life. According to Raymond, trust in mathematics are defined as "personal judgments about mathematics formulated from experiences in math". Similar thing is stated by Eleftheories & Theodosios (2007) "We will use the term "beliefs" in the meaning of personal judgments and views, which constitute one's subjective knowledge, which does not need formal justification".

III. CONCLUTION

As the importance of students' Self-Belief in improving learning achievement of mathematics and mathematical characteristics of primary school in concrete learning-oriented, then the use of hypnoteaching method with all its advantages have strong relevance to be applied in teaching mathematics. This is because the method has great potential in ensuring students on their success in learning mathematics.

Hypnoteaching method focuses on verbal communication filled with positive suggestions, so that students feel comfortable and high concentrated in the learning process. The atmosphere as this will enable students to absorb and understand the lessons. In addition, this method also implied to an increased interest, motivation, confidence and mathematics learning achievement of students. Strong confidence makes the negative perception of students towards teacher and mathematics will change. Mathematics subjects will be eagerly awaited by the students every day, for teacher and learning materials taught are very interesting, fun and easy to understand.

However, success in improving students' confidence depends on the ability of teacher applying methods hypnoteaching. In the process of implementing this method the teacher required: (1) Having the intention and motivation inside; (2) Pacing; (3) leading; (4) providing positive words; (5) Giving praise; (6) Modeling and (7) mastering the material. The reliability of teacher in implementing all of the syntaxes of this method becomes the deciding factor in the successful use of hypnoteaching method, which is expected to realize the goal of learning and growing students' self-belief in mathematics.

Analyze of The Creative Thinking Level of Students Junior High School Viewed From Mathematics Anxiety

Isnaeni Umi Machromah[1], Budi Usodo[2].
[1]Universitas Muhammadiyah Surakarta
[2]Sebelas Maret University
isnaeniumi@ums.ac.id

***Abstract*—**This research was a qualitative descriptive research. Creativity is an important aspect to face the global challenges. Creativity is the product of creative thinking. By means of creative thinking, people can create something new and different, and people also can solve the problem with the various of problem solving. Creative thinking is not a talent. It is a skill that can be learnt. It improves people by adding strength to their natural abilities which improves teamwork, productivity and where appropriate profits. Creative thinking is needed for students to develop their thinking system and it is important for supporting them to solve the problem in the real life. Every students has different levels of creative thinking, specifically for mathematics creative thinking. The aim of this research was to analyze the level of creative thinking of junior high school students beside on mathematics anxiety's students. The subjects of this research were taken by using purposive sampling. The subjects of this research were six persons from 9th grade student of SMP N 3 Colomadu Karanganyar regency. The data were collected by questionnaire and task-based interview technique and validated by using time triangulation. Analyze of the data used data reduction, presentation, and conclusion. The result of this research showed: (1) students with high mathematics anxiety had creative thinking level 1 (almost not creative), (2) students with medium mathematics anxiety had creative thinking level 1 (almost not creative) and creative thinking level 2 (quite creative), (3) students with low mathematics anxiety had creative thinking level 2 (quite creative).

Keywords:*creative thinking level, mathematics anxiety.*

I. INTRODUCTION

One of the main purposes in mathematics learning is developing creative thinking skills. Creative thinking skill is an ability to face mathematics problem in order to get its solution. Creative thinking skill is not only to get the solution of the mathematics problems but also for the problem at their real life. Therefore, creative thinking skill has to be developed in mathematics learning. In spite of creative thinking skill is important in mathematics learning, the fact is creative thinking skill have not been given any attention [1]. Sisk in [2] described that mathematics learning was studied commonly by introduce the formula in mathematics and the concept verbally for the students. There is no attention about student's understanding the formula and concept. Developing the logical reasoning, creative and problem solving thinking skills have not noticed yet in mathematics learning. This condition can lead the students off the development of imagination and creativity optimally. It caused the students do not trained for doing intuition, imagining, and trying to solve the problem with various solution.

The research of [3] shows that there are positive influence between creativity and achievement of 11st grade senior high school student. it means if student's creativity was increased, then student's achievement will be increased. In addition, the research of [4] shows the equivalent result, there were positive and signification influence between creativity and achievement of 9th grade junior high school student. Based on two research mentioned, it can be concluded that student's creativity influences student's achievement. If student's achievement is low, then one of the influential elements is student's creativity and it is said that student's creativity is low.

The Percentage from the result of UN 2014/2015 at Karanganyar shows that the test result of plane area material is 56,46%, it is lower than the result of the others material, that is 89,77%. It shows that the student's achievement on plane area material is low, so it means that the student's creativity is low as well. The first survey that have been done by giving mathematics problem solving-task about plane area material and the result, there is different level about student's level of creative thinking, that is level 1 and level 2.

The research from [5] shows that there was various level of student's creative thinking in mathematics problem solving viewed from gender and motivation. As pointed in [5], motivation is an internal condition which can determine behavior and it influences student's problem solving. So, the internal element influences student's level of thinking skill. However, does it influence to the student's level of creative thinking skill. Mathematics anxiety is student's internal factor influences student in problem that problem-solving activity, then it would be researched about various level of creative thinking viewed from mathematics anxiety.

There are many students feel hard to get solution when solving the mathematics problem. Sometime, they also feel not good enough at mathematics learning. That condition can head off the students reach the aim of learning in mathematics learning. One of the problems is mathematics anxiety which felt by students. The anxiety appear as the result from student's experience in mathematics learning. The condition where students feel worried and strained were called as mathematics anxiety.

Mathematics anxiety is a condition that headed off the students to reach learning experience and mathematics assessment [6]. Reference [7] defines the mathematics anxiety as worried and strained feeling and it annoyed the people when facing mathematics not only numeral manipulation but also mathematics problem solving in mathematics learning and the real life. Reference [8] describes the indicator of the students who have mathematic anxiety, that are (a) the students was difficult for doing mathematics, (b) the students avoided mathematics class, (c) the student felt sick, dizzy, afraid, and panic, (d) the student didn't solve the mathematics task. Reference [8] classified four level of mathematics anxiety that were high mathematics anxiety, medium mathematics anxiety, low mathematics anxiety, and no mathematics anxiety. This research used three kind level of mathematics anxiety, that were high level, medium level, and low level of mathematics anxiety

Mathematics anxiety which felt by student would influence their psychic and emotional. Reference [9] describes about mood and emotional were center of thinking process. So, the mathematics anxiety would disturb process of thinking, specifically creative thinking process in mathematics learning and mathematics problem solving. Agree with that, [10] at his research showed that positive emotional determined the better result at three dimension of creativity that was fluency, flexibility, and novelty. It means, the negative emotion caused the negative impact for creativity. The result of Foong as in [11] research concluded that not only mathematics anxiety but also mathematics task anxiety had negative correlation with student's mathematics achievement. Specifically about creativity, Haylock as in [12] describes that the high creativity of mathematics would make student have low level of mathematics anxiety.

Reference [13] has researched about level of student's creative thinking in mathematics problem solving and problem posing. The result was gotten the level of student creative thinking and characteristic of creative thinking stage that is synthesis the idea, building the idea, planning to apply the idea, and applying the different idea on every level of creative thinking. The result of mathematics creative thinking level were level 4 (very creative), level 3(creative), level 2 (quite creative), level 1(almost not creative), and level 0 (not creative).

Edward as in [7] defines that Creative thinking is not a talent, it is a skill that can be learnt. It improves people by adding strength to their natural abilities which improves team work, productivity and where appropriate profits. So, the creativity can be developed based on personality skill. Reference [14] defines that creative was an element of synthetic skill (divergent thinking), analyzed skill (critic and convergent thinking), and practice skill. Reference [15] defines about creativity of mathematics as a thinking abilities divergently and production the number of idea originally.

Level of creative thinking was stage of thinking hierarchical based on the product of mathematics creative thinking that was viewed from aspect of creativity. The aspect of creativity was fluency, flexibility, and novelty. The fluency is indicated when the student fluently produces different ideas which were appropriate to the question task. The flexibility refers production of some ideas which were used to solve a task. The novelty is the main characteristic to assess the product of creative thinking. The three aspect of creativity not only determined on mathematics problem solving, but also on mathematics problem posing. This research used modify of the level of creative thinking which developed by reference [13]. The levels are (1) level 4 (very creative), the subject fulfill the fluency, flexibility, and novelty aspect; level 3(creative), the subject fulfill the fluency and novelty aspect; level 2 (quite creative), the subject fulfill the fluency and flexibility aspect; level 1(almost not creative) the subject fulfill the fluency aspect, and level 0 (not creative), the subject doesn't fulfill any aspect of mathematics creative thinking.

Based on that description, there are relationship between level of creativity and level of mathematics anxiety. The level of creative thinking is the level of creativity for doing and getting solution in mathematics problem solving. The level of mathematics anxiety shows the level of student's anxiety when facing the mathematics learning and mathematics problem solving. In this research, the level of creative thinking use five classification as modify from reference [13] and the aspects of creative thinking are fluency, flexibility, and novelty. In this research, the indicator and level of mathematics anxiety use three classification, that are high level, moderate level and low level of mathematics anxiety. So, the aim of this research is to analyze how do the level of creative thinking on mathematics problem solving viewed from mathematics anxiety.

II. METHOD

The research approach was qualitative research which aim to identify the level of student's creative thinking viewed from student's mathematics anxiety. The method for determining a sample subject used purposive sampling. The subjects of this research were six persons from 9th grade student of SMP N 3 Colomadu Karanganyar regency. At the first time, students were given questionnair of mathematics anxiety. From the result of this questionnair, students were classified based on the level of mathematics anxiety. The level of mathematics anxiety are high mathematics anxiety, moderate mathematics anxiety, low mathematics anxiety, and no mathematics anxiety. Subjects of this research were selected from high level, medium level, and low level of mathematics anxiety. Finally, the subjects were six students and they are two students have high mathematics anxiety, two students have medium mathematics anxiety, and two students have low mathematics anxiety.

The data were collected through questionnaire and the task-based interview to the 9th grade students on junior secondary school. The main instrument at this research was the researcher. The secondary instrument at this research were (1) the questionnair of mathematics anxiety, (2) the task of problem solving, and (3) the guide of interview. The questionnaire of mathematics anxiety was used to get information about student's mathematics anxiety and the result was used to determine the subjects of this research. The problem solving task was used to identify the level of creative thinking students. The task was an open-ended task.

Triangulation was conducted by giving another equivalent task for students and interviewing them again deeply. The student's work was analyzed by identifying the correctness of the answer, then checking for aspects of creative thinking (fluency, flexibility, and novelty) in problem solving. Analyze of the data used data reduction, presentation, and conclusion.

III. RESULT AND DISCUSSION

A. Result

The results of this research were (1) the student, who had high mathematic anxiety, got level 1 (almost not creative) of creative thinking, (2) the students, who had moderate mathematic anxiety, got level 1 (almost not creative) and level 2 (quite creative) of creative thinking, and (3) the student, who had high mathematic anxiety, got level 2 (quite creative) of creative thinking.

B. Discussion

The result of this research described the level of creative thinking students based on their level of mathematics anxiety. The subject who had high mathematic anxiety could solve the problem correctly and they solved the problem by the proper algorithm. They could not give another solution for the problem. They didn't have any interest for solving the problem by other method. So, the subject who has high mathematics anxiety just filled the fluency aspect. Based on the level of creative thinking, the subject that just filled the fluency aspect had the level 1 (almost not creative) of creative thinking.

Two students who have moderate mathematics anxiety had the different result. One of the student could solve the problem correctly and he solved the problem by the proper algorithm. He could not give another solution for the problem. The other student could solve the problem correctly and he could solved the problem with other solution. So, the first student just filled the fluency aspect and the others could fill fluency and flexibility aspect. Based on the level of creative thinking, the subject that just fulfilled the fluency aspect had the level 1 (almost not creative) and the subject that fulfilled the fluency and flexibility aspect have the level 2 (quite creative).

The subjects who had low mathematics anxiety could solve the problem correctly and they could solved the problem with other solution. So, they could fulfill fluency and flexibility aspect. Based on the level of creative thinking, the subject that fulfilled the fluency and flexibility aspect had the level 2 (quite creative) of creative thinking. Based on field note, the subject who had low level of mathematics anxiety did not look stressed when doing mathematics problem. At the first time, subject did not feel confident when asked to do mathematics problem. The subject was afraid if the problem was difficult and he could not solve the problem. But the subject felt more confident than before when he was reading and understanding the problem. It showed that the subject felt anxiety when first facing mathematics problem, because the subject prejudiced that the problem would be so difficult for him. This anxiety was low level of mathematics anxiety. As in [16], the people who had low level of mathematics anxiety would feel unconfident and afraid, sometime there were physical indication, like tremble. Agree with that, [17] described that people who had mathematics anxiety was strained and anxious, but that feeling would come infrequently for the people who had low level of mathematics anxiety. So, the subject who had low level of mathematics anxiety could solve the mathematics problem properly, but when they met the difficult one, they thought to give up with the problem.

The result of this research was supporting the other research which the conclusion of its research was the student who had low level of mathematics anxiety have the better achievement than the student who had high and moderate level of mathematics anxiety. The low level of mathematics anxiety was brought positive influence for student on mathematics problem solving and their mathematics achievement. The subject who had low level of mathematics anxiety well did every stage of creative thinking process on mathematics problem solving at circle material. The subject through every stage of creative thinking process that is preparation, incubation, illumination, and verification. The subject who had low level of mathematics anxiety also fulfilled the fluency and flexibility aspect of creative thinking. By the creative thinking like that, the student's achievement would be better than the subject who had high and moderate level of mathematics anxiety. The result of this research, the subject who had low mathematics anxiety had level 2 (quite creative) of creative thinking and the subject who had high level of mathematics anxiety had level 1 (almost not creative) of creative thinking. It means the level of subject who had low level of mathematics anxiety higher than subject who had high level of mathematics anxiety.

IV. CONCLUSION

The conclusion of this research were: (1) the student who have low level of mathematics anxiety had level 2 of creative thinking (quite creative), (2) the student who have moderate level of mathematics anxiety had level 2 of creative thinking (quite cre ative) and level 1 of creative thinking (almost not creative), (3) the student who have high level of mathematics anxiety had level 1 of creative thinking (almost not creative).

The suggestion based on this research were: (1) teacher can give open ended and challenge problem, and ask the student to solve the problem with various solution, so the student will be trained to increase their creativity on mathematics problem solving; (2) teacher should give motivation for student, especially student who have high level of mathematics anxiety, because the student feels afraid for facing the mathematics and hard mathematics problem, and the teacher can contiguous the student who have moderate and low level of mathematics anxiety and give the problem as high as their skill; (3) the student who have mathematics anxiety should do cleverly the mathematics problem which easier, then the student will habitual about mathematics problem and the student can understand in mathematics learning step by step; (4) the result of this research can be reference for another researcher for developing the model of learning which increasing student's creativity and decreasing student's mathematics anxiety.

The Technique and Validation of Composing the Attitude Assessment Instrument for Junior High School Mathematics Learning Based on Curriculum 2013

Kana Hidayati
Department of Mathematics Education
Yogyakarta State University
kana_hidayati@yahoo.com

***Abstract*—**Assessment is one of the important components that have to be attention in order to support the success of Junior High School Mathematics learning implementation based on Curriculum 2013. The accountable assessment results will be obtained if the assessment instrument uses a good quality that is proved by having a good content validity and align with Curriculum 2013. Therefore, assessment of Junior High School Mathematics learning based on Curriculum 2013 should use appropriate instrument arranged through the appropriate steps in order to generate a good quality and accountable assessment instrument..Through some theories, this paper studies the technique of composing the attitude assessment instrument for Junior High School Mathematics learning that can generate the instrument of attitude assessment based on Curriculum 2013. The technique of composing instrument in this paper contains of steps to compose the assessment instrument that can generate attitude assessment instrument theoretically. It shows that attitude assessment instrument has a good content validity and it is align with Curriculum 2013. In addition, this paper also discusses the studies about how to validate the instrument in order to get a good content validity and align with Curriculum 2013.

Keywords: *assessment, attitude, instrument, mathematics, validation*

I. INTRODUCTION

Through the curriculum in 2013, the government tries to develop Graduate Competency Standards increasing from the previous curriculum and balancing between soft skills and hard skills. It changes one important elements in Curriculum 2013. The changing is the standard educational assessment. Based on Permendikbud No. 53 of 2015, it states that the scope of the assessment of learning outcomes by educators in primary and secondary education includes aspects of attitudes, aspects of knowledge and skills aspects. The assessment objectives of learning outcomes by educators in primary and secondary education by Permendikbud No. 53 of 2015 are: (a) determine the level of mastery of competencies; (b) establish mastery of competency; (c) establish a program for remediation or enrichment based on the level of mastery of competencies; and (d) improve the learning process. It means that the assessment based on Curriculum 2013 need qualified assessment instrument that can measure the achievement of students competency well and able to fulfill the accuracy and accountability of the assessment results.

Based on the reflection results of the implementation Curriculum 2013 which is done by the coach directorate of Junior High School in 2014 show that based on the quantitative report approximately 34% teachers who had been trained were less understanding of assessment based Curriculum 2013. Relate to the assessment process shows that about 22% teachers have difficulty in assessing the attitude aspect and 14% teachers have difficulty in assessing the skill aspect. Based on the qualitative report shows that the trainer's understanding toward assessment aspect based on Curriculum 2013 was still lack. The teachers expect special training or assistance related to the particular assessment [1]. In addition, more than 50% teacher respondents state that they have not been able to design, implement, and process the results of an assessment well. The main difficulty faced, such as formulate indicators, formulate points of the instrument, and implement, the assessment attitude by various techniques [2].

From the results of reviews these reflections, through the revision of the Curriculum 2013 which will be implemented in the beginning of the academic year 2016/2017, the government simplifies the assessment activity that should be done by teachers. Assessment activity is made simpler, affordable to do, not overlap, not a burden for teachers/students, but still maintaining the principles and rules of assessment. The simplification is the assessment for attitude aspects (social and spiritual) done by PPKn teachers and religious education teachers, while other teachers who teach other subjects only assess the academic aspects of the field that is taught. Teacher of other subjects, such as math, assesses attitude aspect but it just to add a reference or input in assessing the students' attitude. In addition, the assessment activities carried out do not only assessment of learning, but also assessment for learning and assessment as learning.

One of the criteria that should be considered related to the quality of the attitude assessment instrument is validity. During this time, the validity verification of an attitude assessment instruments are generally seen by content validity and construct validity. Especially for content validity evidence is generally done by rational analysis through expert judgment and evidence of construct validity with factor analysis. Development in the theory of measurement shows that the content validity of an assessment instrument can also be obtained through the study of alignment between the assessment and standards in the curriculum. This is as Ananda which states that alignment can be source for evidence of content validity, construct, and consequential [3].

Based on the statements above, it shows that student learning outcomes based curriculum 2013 measured on aspects of attitudes, knowledge, and skills. But until now, the teachers including math teachers still have difficulty in arranging an assessment instrument in particular on attitude aspect. Therefore, the composing guideline of attitude assessment instrument is urgently needed by teachers in composing the instrument that will be used in conducting the assessment. Besides, the paper will also discuss how to prove the validity of its contents. The composing technique of attitude assessment instruments is the steps of composing the attitude assessment instruments that can generate qualified attitude assessment instruments and align with Curriculum 2013.

II. ATTITUDE ASSESSMENT IN MATHEMATICS LEARNING OF JUNIOR HIGH SCHOOL BASED CURRICULUM 2013

Understanding of attitudes have been suggested by experts as Baron & Byrne that gives a definition of the attitude that someone provisions in evaluating either positively or negatively towards others, oneself, thing, or matter [4]. Attitude has constant characteristic all the time so momentary feeling is not counted as an attitude. This is similar to Ajzen who argues the definition of attitude as the disposition of the individual to respond positively or negatively to an object, person, institution, or event [5**]**. Based on some opinions above, it can be concluded that the attitude is a state in human beings who motivate to act or behave in a permanent or momentary feeling either positive or negative to the situation or conditions in the surrounding environment.

It is not different from the various definitions about the attitude, based on the Curriculum 2013, the attitude is defined as an expression of values or philosophy of life that is owned by someone and manifested in behavior. Attitude assessment in mathematics is an activity to identify trends spiritual and social behavior of students in daily life inside and outside the classroom as a result of education [2]. Based on Curriculum 2013 competencies characteristic of attitude dimension refers to the affective domain taxonomy Krathwohl [6]. Based on guideline of learning outcomes assessment by educators in 2015, it is mentioned that the attitude assessment is made by the subject teacher (during the learning process in school hours) naturally, counseling teachers, and homeroom (during the students outside class hours) which is written in the journal. Besides, self-assessment and peer-assessment can be done in the framework of development and character formation of students which the results can be used as one of the confirmation data of the overall attitudes. The attitude assessment scheme is presented in Figure 1 below.

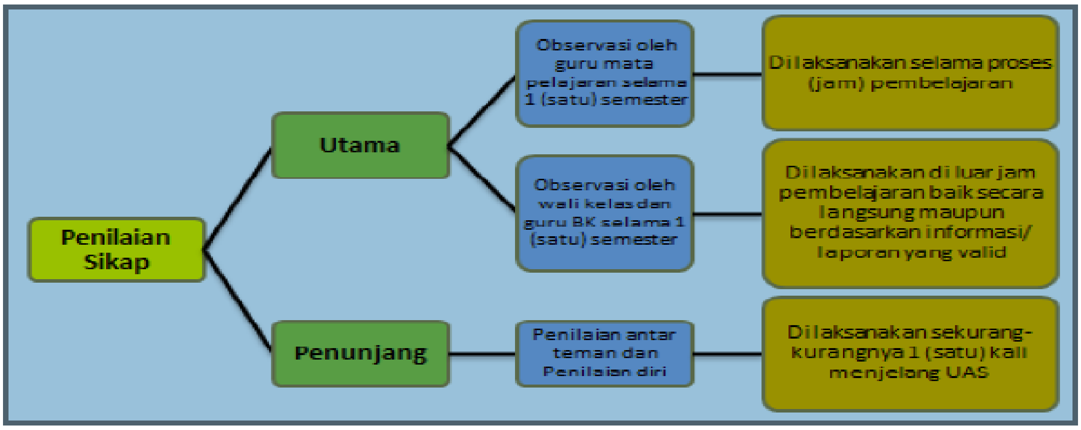

Figure 1.The Attitude Assessment Scheme [2]

III. TECHNIQUE OF COMPOSING ATTITUDE ASSESSMENT INSTRUMENT

An assessment instrument is a prominent key of the successful implementation of educational assessment activities. The quality of the assessment results depends on the quality of assessment instruments used. Therefore, assessment instruments should be composed and developed through the steps that can be accounted so the result of the assessment that is obtained is accurate and reliable. If the assessment instrument is badly designed, the assessment which is done will waste of time and cost. Conversely, if the assessment instrument is designed well, the results can support the quality of information obtained from the assessment results even be one of the factors that can improve the learning outcomes of students.

Nitko state five basic principles in assessment, such as: (1) determine clearly what will be assessed; (2) Ensure that the assessment technique selected suitable for assessing what will be assessed; (3) Ensure that the assessment techniques are selected according to the students' needs; (4) If possible, make sure the use of various indicators of learning outcomes for each assessment targets; and (5) Ensure that when interpreting the results of the assessment, had been obtained enough information about the students [7]. Development of instruments according to Wilson, such as: (1) map constructs, (2) items, (3) scores items, and (4) measurement. In general, based on the Queensland Studies Authority procedure development of assessment instruments that can be done by teachers includes steps as follows. (1) Start with a general purpose syllabus: determining the general objectives aspect which can be assessed; (2) refers to the standard matrix for relevant descriptions to the selected general purpose; (3) develop instruments that enable learners to show attributes assessed; and (4) develop criteria on instruments sheet based on the selected attributes of a standard matrix. Related to the attitude assessment, Djemari Mardapi suggests steps of the development of affective assessment instruments as follows: (1) determine the specifications of instruments, (2) writing instruments, (3) determine the scale of the instrument, (4) determine the system of scoring, (5) examine the instruments, (6) test, (7) analyze the instruments, (8) assemble instruments, (9) carry out measurements, and (10) interpret measurement results [8].

Attitude assessment based Curriculum 2013 refers to the affective domain taxonomy of Krathwohl the which includes five stages, such as receiving, responding, valuing, organization, and characterization by value as follows: (1) Receiving, it describes the stages awareness or sensitivity to the presence of certain ideas, material, or phenomena and are willing to tolerate the willingness to recognize the existence of a phenomenon in its environment. This stage is the opener one's senses to the world; (2) Responding, it is the second taxonomic phase as form of reaction to the phenomena that exist in the environment. At this stage learners do not only pay attention to the phenomenon but also give react. A high level at this stage is interest; (3) Valuing, it is relating to award or assessment given on an object, phenomenon, or behavior. Degree range is from receiving a value to the level of commitment. Assess stage or appreciate do not only accept but also assess the value of a concept or good or bad phenomenon; (4) Organization, it is fourth phase that combines different values, solves conflicts, and establish a consistent value system. Organizing occurs when a person is in a situation where there is more than one value; and (5) characterization by a value or value complex, it is the highest stage which means to act in a manner consistent with the values of individuals who have been internalized. At this stage, learners have a value system that controls behavior until a certain time to form a lifestyle or one-self [9].

Based on the reasons the above, it can be arranged a composing technique of assessment instrument for mathematics which refers to affective taxonomy by Krathwohl with the following steps:
(1) Determine the purpose of the attitude assessment which will be assessed.
This step is done by looking at the basic framework and structure of Curriculum 2013 for junior high school mathematics especially Basic Competency on the material that will be assessed.
Example:
The following Basic Competence in statistical material based Curriculum 2013 class VII.
Basic Competencies:
2.3. Behave honestly and responsibly as a implementation form of honesty in reporting observational data.
Based on the basic competencies, it can be determined the purposes of assessment that will be done by assessing the attainment of students' attitude on the matter of statistics and opportunities. The attitude assessed are being honest and responsible attitude.
(2) Develop the lattice of attitude assessment instruments.
Composing the lattice of assessment instrument is done by determining the conceptual definition of values of attitude which will be assessed. Conceptual definition is formulated based on the results of theoretical studies of various reference or expert opinion. Referring to the conceptual definition, it is formulated operational which is explained into operational indicators and each indicator also refers to the charge Krathwohl taxonomy. The content of affective aspect according to taxonomy Krathwohl include: receiving, responding, valuing, organization, and characterization by a value or value complex.
(3) Choose the assessment techniques and determine the type of measurement scale.
Based Curriculum 2013, the attitude assessment techniques that can be used is observation, self-assessment and peer assessment. After selecting assessment techniques, it is determined the type of measurement scale for example using the subject scale or a response scale in the form of Thurstone scale, Likert scale, Beda Semantics scale, or any other scale.
Example:
Assessment techniques used to measure students' integrity is honest self-assessment in the form of honest attitude scale, in the form of subject scale with three possible answers.
(4) Write instruments items and determine the scoring system and method of interpretation.
Writing items of attitude assessment instruments refers to the scale of measurement that has been determined and indicators contained in the lattice instruments. Scoring system and interpretation method also depends on the measurement scale used.
Example:
The system of scoring for honest attitude scale forms scaling subject with three possible answers are: Answers option which indicate the most honest attitude (Score: 2); Answer option which indicates that answer is less honest attitude (Score: 1); Answer option that does not indicate an honest attitude (Score: 0). The method of interpretation can be made by referring to the following categorization of honest attitude.

Table 1. Categorization of Honest Attitude

Scores of Students	Category Attitudes Honest
$X \geq \bar{x} + 1,5\ s_x$	Very high
$\bar{x} \leq X < \bar{x} + 1,5\ s_x$	High
$\bar{x} - 1,5\ s_x \leq X < \bar{x}$	Less
$X \leq \bar{x} - 1,5\ s_x$	Low

IV. THE CONTENTS VALIDITY OF ATTITUDE ISNTRUMENT

Validity verification of the attitude assessment instruments generally emphasize to content validity and construct validity. The content validity is aimed to know the contents of a measuring instrument if it is representative or not. According Sireci & Bond state that evidence of the content validity of an instrument can be done by traditional and modern approaches [10]. Traditionally, an estimate of the content validity of an instrument is obtained by examining the items instruments reflects and does not reflect the content domain. The most common method to vivificate the validity based content is through expert judgment that look items in terms of: (a) examine the objectives that are tested, (b) assess the item representing content meant, and (c) assess the items which are relevant to the domains tested. Lawshe suggests Content Validity Ratio (CVR) to measure the degree of expert agreement of the items [11]. The level of the contents validity expressed in a single indicator that amount ranging from -1 to 1. Lawshe proposes that each appraiser consisting of the judging panel answer the question for each item with three possible answers: (1) essential, (2) useful but not essential, (3) not required. The formula for calculating the CVR is as follows.

$$CVR = \frac{ne-(\frac{N}{2})}{\frac{N}{2}} \tag{1}$$

where:
ne: The number of experts who give essential response to an item; N: Number of experts.

CVR calculation is made on each item. According to Lawshe, generally, if more than half of panelists show that the item is important/essential, reviews those items have at least the validity of the content. Specifically, CVR score of each item can also be compared with a minimum score of CVR with acceptance of 0,05 as researched by Lawshe.

Another approach related content validity coefficients suggested by Aiken [12]. Aiken V Formula for calculating the content validity coefficient based on the assessment results from the expert panel of n people toward an item in terms of these items represents the measured construct. Aiken V coefficient value ranges between 0 - 1. The coefficient is higher than 0,5 can be considered to have adequate content validity. The formula for V Aiken is as follows.

$$V = \frac{S}{[nx\ (c-1)]} \tag{2}$$

$$S = \Sigma \text{ ni (r-lo)}$$

where:
V: the validity index of Aiken; ni: Number of experts choosing the criteria i; r: Criteria to i.
lo: lowest rate; n: The number of all the experts; c: Number rating/criteria.

As a modern, Sireci & Bond argue that new approaches developing related to the verification content validity is through the test alignment [13]. Alignment between assessment and standards can be defined as the level of agreement that measures the consistency between the standards or curriculum content for a particular subject with the assessment to measure student learning outcomes [13]. This shows that the purpose of the test is to establish the suitability between assessing suitability and content of subjects as contained in the basic competence in the subject. Ndiovu & Mji state Alignment index calculation can be done by using alignment index formula of Porter. Alignment index ranges from 0 (no alignment) to 1 (perfect alignment). The formula alignment of Porter index is as follows [14].

$$P = 1 - \frac{\sum_{k=1}^{K} \sum_{j}^{J} \left| a_{jk} - b_{jk} \right|}{2} \tag{3}$$

where:
a: The number of lines, K: the number of columns in each matrix X and Y,
x_{jk} and y_{jk}: the ratio of cells in row j and k columns for each matrix ratio of x and y.

In general, the index of alignment Porter (P) can be determined in four steps as follows: (1) make a matrix of frequencies for the two documents which are compared, for example, give label as a matrix X and Matrix Y, (2) for each cell in the matrix X and Y, the ratio is calculated by comparing the number of cells in a cell with amount of numbers in each matrix. Label this as aratio matrix x and y, (3) For every row j and column k in the ratio matrix, calculated the absolute value of the difference between the ratio in cells x_{jk} and y_{jk}, and (4) Calculated alignment index.

V. CONCLUSIONS

Composing the attitude assessment instruments in mathematics based on the Curriculum 2013 can be done by steps as follows: (1) Determine the attitude assessment objectives which will be assessed; (2) Develop lattice of attitude assessment instruments for each indicator refers to the operational definition of attitude assessed and affective taxonomy of Krathwohl; (3) Choose the assessment techniques and determine the type of measurement scale; and (4) Write instruments items and determine the scoring system and the method of interpretation. The validity verification of the content on the attitude assessment instrument can be done traditionally by using CVR index and index of Aiken and in modern way by using index alignment.

The Role of Metacognitive in Problem Solving: A Case in Logarithm

Masduki, Heri Kusuma
Department of Mathematics Education, Universitas Muhammadiyah Surakarta
Corresponding author: masduki@ums.ac.id

***Abstract*—**Problem solving ability is the most important goals of learning mathematics. It needs the ability to understand the problem, control, and monitor cognitive processes. Metacognitive skills are a very important element to assist individuals in identifying and formulating a framework or strategy work. The ability of problem-solving strategy is one of the important factors in solving the problem. Lack to draw up a proper strategy will lead to failure anyway in solving problems. This paper presents the results of tests and interviews with two students in solving of the logarithm. The first subject was a student who successfully solve problems with a high score while the second one was low. The results of this study showed that the student with high performance in mathematics able to plan the solve of problems, able to devise problem-solving strategies, monitor of each step, and evaluate the results. In another word, the student has the ability to use metacognitive skills. Conversely, the student with low mathematics performance indicates a failure in the use of metacognitive skills. The results showed a close connection between the problem solving and metacognitive. That skills will aid students in understanding, strategic planning, monitoring the completion of the steps, and evaluate the results obtained. In other words, metacognitive skills will help students in problem-solving.

Keywords: *metacognitive, problem solving, ratio*

I. INTRODUCTION

Problem-solving ability is the most important goal in mathematics learning. NCTM (*National Council of Teachers of Mathematics*) in the *Principles and Standards for School Mathematics* states: "*a major goal of mathematics is to equip students with the knowledge and tools that enable them to formulate, approach, and solve problems beyond Reviews those that they have studied*" [11]. It means the ability to use their prior knowledge to solve mathematical problems is the essence of mathematics. Problem-solving skills in mathematics is the ability to use prior knowledge or connecting mathematical concepts to solve problems that arise in actual situations or "*real world problems*". It means "*problems*" in problem solving are complex, non-routine, open-ended, and challenging. NCTM [11] states that "*Problem solving means engaging in a task for the which the solution method is not known in advance* .." It means there is no method or the regular way to solve the problem.

To success in solving the problems in mathematics required the ability to understand the problem, control and monitor a cognitive process, or in other words metacognitive skills in problem-solving [2,3,8,10,16], as well as the motivation to solve the problem [10]. Metacognitive skills are also very important components to assist individuals in identifying and formulating a framework or strategy to solve the problems (Davidson and Sternberg in [16]). The ability to design the strategy in problem solving is one of the important factors in solving the problem [3]. Failure to draw up a proper strategy will lead to failure anyway in solving problems. A factor that can hinder problem solving is the *mental set* that frame of mind that involves an existing model to represent a problem, the context of the problem, or procedure for solving a problem. Another term for the mental set is *entrenchment* when problem solver has the mental set that is entrenched, they are fixated on a strategy that usually works well in solving routine problems but that strategy does not work well in solving the non-routine problems [17].

Metacognitive terms in education have been quite widely used in recent times relating to optimizing students' skills in problem solving [6], or students' achievement [5]. The important goals in involves metacognitive in learning activities are to improve the quality of learning, especially in mathematics.

There is no agreement among experts on the definition of metacognitive formally, due to the many different kinds of knowledge and processes included in the metacognitive term [12]. But in general, there is a thread that can be drawn to connect the various opinions.

There are several definitions of metacognitive that developed in the field of cognitive psychology including Flavell and Brown. Flavell (in [9]) defines the metacognitive as: ".. *the ability to understand and monitor one's own thoughts and the Assumptions and implications of one's activities*." In other words metacognitive as the ability to understand and monitor the activity of thinking themselves and assumptions as well as the implications of that person's activities. This opinion emphasizes the metacognitive as the ability to understand and monitor the activity of thinking so that the metacognitive process of each person will be different according to their ability. Meanwhile, Brown (in [9]) defines the metacognitive with: "... *the degree to which learners are engaged in thinking about themselves, the nature of learning tasks, and the social contexts. ... as being comprised of activities for regulating and monitoring human learning*. " This means metacognitive as an awareness of cognitive activity itself, the method used to control the cognitive process themselves and a mastery of how to direct, plan and monitor cognitive activity. Brown's opinion emphasizing metacognitive as awareness of cognitive activity, in this case, the metacognitive relates to how a person aware of his thinking process. That awareness will materialize in the way a person organize and manage the activity of thinking process.

Flavell tends to view the metacognitive as a knowledge aspects about a person's cognitive while Brown tended to view as a process of arranging a person's cognitive. Although Flavell and Brown had a different point of view about metacognitive, but both argued that metacognitive includes two aspects are interrelated and interdependent on one another. Flavell [4] suggests that metacognitive consisting of 1) metacognitive knowledge, and 2) metacognitive experience or regulation. On the other hand, Brown also divides metacognitive into 1) knowledge about cognition, and 2) regulation of cognition [7]. Metacognitive knowledge is described as knowledge or belief about the factors, variables that affect the individual's cognitive processes [4]. Brown (in [15]) distinguishes three types of metacognitive knowledge namely declarative, procedural, and conditional knowledge. Declarative knowledge refers to knowledge about themselves as learners and knowledge of the factors affecting performance. Procedural knowledge refers to knowledge of how to use procedural skills to execute. While the conditional knowledge is the knowledge of when and how to use a variety of cognitive activity possessed.

Furthermore, the metacognitive regulation also called metacognitive skills are defined as awareness of cognitive activities themselves, a method for regulating the cognitive process, as well as orders to organize and plan cognitive activity. Jacobs & Paris (in [15]) presents three essential components of metacognitive regulation, namely planning, monitoring, and evaluating. Planning involves choosing the appropriate strategy and effective resource allocation thus affecting the performance. Monitoring refers to the self-awareness to monitor understanding and the task performed. While the evaluating is the process of assessing the solution and the learning process which have been done. On the other hand, Lucangeli and Cornodi (in [2]) states four components of metacognitive skills with a prediction, planning, monitoring, and evaluation. Prediction is the activities to distinguish between the difficult and easy problems to be determined exactly how much effort and resources needed to solve the problems. Planning includes analyzing the problem, take back the specific knowledge and skills already possessed, and to develop problem-solving strategies. Monitoring includes activities to monitor each troubleshooting step is carried out. This is to ensure that the strategy that has been formulated goes well to solve the problems. While the evaluation is to assess the results of the activity and the steps used to get answers. Simon (in [2]) provides the third component of metacognitive called conception or faith, namely metacognitive idea or theory of how people think about themselves and others, such as attribution, motivation, and self-esteem.

Based on the data of tenth-grade students' achievement in the logarithm of SMK Muhammadiyah Delanggu odd semester of 2015/2016 academic year consisting of 24 students, as much as 81% get less value from minimum passing criteria. This indicates the lack of students' performance in mathematics learning, especially on the subject of a logarithm. Most of the students have not been able to complete mathematics problems in a systematic manner. They immediately focus on calculations that are procedural without first understanding the purpose of the given problem. This paper presents the role of metacognitive skills to solve mathematical problems, especially in the matter of logarithms.

II. RESEARCH METHOD

This research is qualitative descriptive. The subjects were two students of tenth-grade students' of SMK Muhammadiyah Delanggu, Central Java, with the category of high and low math skills. The subjects are selected by first giving five essay test questions to all students. The fifth question must be completed within 90 minutes. Furthermore, based on the results of the test, the student's ability to solve problems are classified into three categories, namely high, medium, and low. This study will be the focus on with high and low categories students'. The Data will be collected by using observation, test, and interviews. The observation methods used to obtain data about the math learning activities directly and observe the student in completing the questions given by the researcher. The test method used to obtain data on students' ability to solve problems. Meanwhile, the interview method used to find out information on how the metacognitive skills of students in solving logarithms. The Researchers also provide an assessment of the results of student work related to the logarithm. The acquired data were analyzed by reducing the data, presenting the data, and drawing the conclusion. Data reduction was performed by recording the interview result, and observation of teachers and students. The researcher also scored the students' answer related to logarithmic materials. After the data went through reduction process, the data would be presented in a complete narrative text, tables, and records of interview result regarding the students' understanding of logarithmic materials. The last step was to draw conclusion based on the result of data spread

III. RESULT AND DISCUSSION

Based on the test results of 24 students', there were seven students with high math ability and students lower category. The remaining 10 students, that are in the moderate category. Afterward, the students with high category (subject 1) and low (subject 2) are selected as research subjects. In this paper presented the results of the test and a description of metacognitive skills of high and low categories students' in solving problem 3. Problem number 3 is presented as follows:

Question:
Let *log* 2 = 0.3010 and *log* 3 = 0.4771, determine the value of:

a. *log* 12
b. *log* 24

The answer of subjects 1 and 2 in solving problem 3 is presented in Figure 1 and 2 as follows:

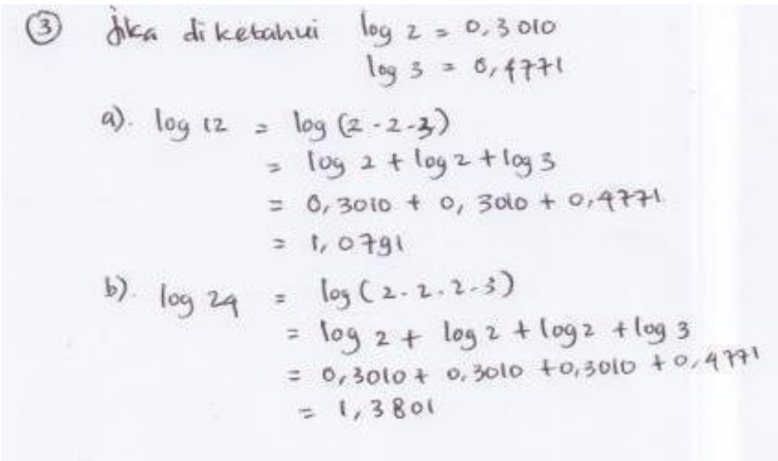

Figure 1. The answer of subject 1

Figure 1 shows the students answer with the high category in solving problem 3. It shows that the students are able to solve problems correctly. Interviews showed that students understand the purpose of the questions that must be resolved namely determining *log* 12 and *log* 24. Students are also able to understand the information given in problem, namely *log* 2 = 0.3010 and *log* 3 = 0.4771. Based on the knowledge that has been owned by the students (prior knowledge), then the students determine the relationship between the known and asked information of the problem. Students said that to determine *to log* 12 first determining the multiplication factors of 12 namely 2, 2, and 3.

Subject 1 : multiplication factors of twelve are 2, 2 and 3. So *log* 12 = *log* (2 x 2 x 3).
Researcher : Why you choose 2 x 2 x 3? Why not 4 x 3?
Subject 1 : Due to the unknown *log* 2 and *log* 3.

ISBN 978-602-74529-0-9

Interviews showed that students were able to determine the relationship between the known information on the matter and the problems in question. Furthermore, students able to connect the data obtained, the *log* 12 = log (2 x 2 x 3), with the knowledge that has been held on the multiplication properties of logarithms.

Subject 1 : Continue finished *log* 12 = *log* 2 + *log* 2 + *log* 3

Researcher : Is it the properties of logarithms?

Subject 1 : yes, there is a property in the logarithm *log* (a x b) = *log* a + log b

Interviews showed that students are able to connect information held previously, namely the properties of logarithms, with the information obtained, the log (2 x 2 x 3). The next step is the completion of procedural involving calculations. Students said that after obtaining the answers to the calculation results, students are reassessing to convince the truth of the estimates obtained. Furthermore, to solve the problem 3.b applies same steps with 3.a.

The metacognitive skills of subject 1 in solving problem 3 looks already well underway. Students have been able to understand the purpose of the problem, the information provided on the issues, and to determine a strategy to solve the problems. This means that the student has the ability to perform well completion planning. Furthermore, students have been also able to connect the knowledge that has been owned by information obtained from the problem. Students are doing step by step systematically in order to know where the mistakes if the answer is incorrect. This indicates that the student has the ability to monitor every step in solving a problem. Monitoring measures are taken to ensure the completion of the procedure is done properly. Metacognitive skills that last aspect is evaluation where students have to recalculate to convince the truth of the answers obtained. These results indicate that students who able to control the metacognitive skills will be able to solve the problems appropriately. In other words, metacognitive has a very important role to solve the problems.

Furthermore, the answer of the students with low math skills to solve problems 3 is presented in Figure 2 below:

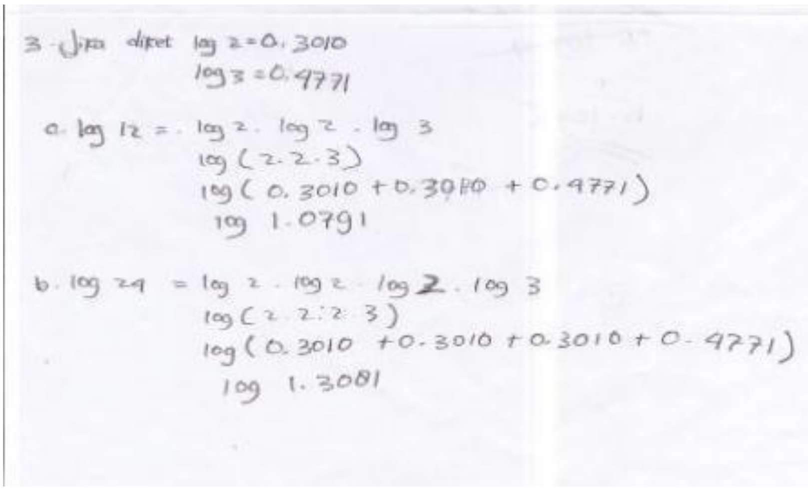

Figure 2. The answer of subject 2

Figure 2 shows that the students answer is not correct. Students can understand the information provided by the problem that is *log* 2 = 0.3010 and *log* 3 = 0.4771. He also understands the purpose of the questions that must be solved namely determining *log* 12 and *log* 24. However, students are not able to determine the exact relationship between the known information with information obtained from the problem. Students understand the multiplication factor of 12 is 2, 2, 3. But the students are not able to connect the concept of multiplying a number by multiplying the logarithms so that students write the *log* 12 = *log* 2 x *log* 2 x *log* 3.

Subject 2 : multiplication factors of 12 is 2, 2, 3

Researcher : How *log* 12 can be *log* 2 x *log* 2 x *log* 3?

Subject 2 : due to the multiplication factors of 12.

The interview results indicate that students are not able to link their prior knowledge with the new knowledge so that they encountered an error. The same thing happened to the completion of a problem 3.b.

Subject 2 is able to understand the information provided by the problem and understand the purpose of the question (asked by the question). But the students failed to design the problem-solving strategy even though he have been able to determine the factors of 12 are 2, 2, and 3. Students are not able to connect the concept of multiplication in decimal numbers with on logarithms. This means that aspects of metacognitive skills in planning the settlement did not go well. Furthermore, a failure in all aspects of planning resulted in less appropriate in solving steps . It appears that students write the *log* (2 x 2 x 3) = *log* (.3010 + .3010 + .4771). The results of these calculations show that students fail to understand the nature of multiplication logarithm.

Researcher : Why *log* (2 x 2 x 3) could be a *log* (.3010 + .3010 + .4771)?
Subject 2 : due to the nature of the logarithm multiplication in that way.
This shows that students do not carry out the monitoring to ascertain whether the steps undertaken are in accordance with the procedure. These results indicate that the failure of students in the use of metacognitive skills will have an impact on the results were not correctly.

The results of this study provide additional information about the importance of metacognitive skills in solving mathematics problems. These results are in line with Bayat and Tarmizi [1] which conducted a study of 86 first-year students who took the algebra courses at universities in Malaysia. The study wanted to test the correlation between metacognitive strategies with the students' ability in solving algebra problems. The results showed that there is a significant impact on the ability of metacognitive strategies algebra students. In other words, students are able to take advantage of metacognitive strategies will be able to solve the problems of algebra well too.

IV. CONCLUSION

Based on the research of two students with high and low math category shows that students who able to plan completion, monitoring every step of completion, and evaluate the results obtained will be able to solve the problems appropriately. In other words, students are able to use metacognitive skills in solving the problems will get the results as expected. Conversely, students who have failed in the use of metacognitive skills would not be able to solve the problems appropriately. Thus, metacognitive skills have a very important role to solve the problems, especially in mathematics.

Developing Mathematics Instructional Package with POGIL that is Oriented to The Competences in Curriculum 2013

Mega Eriska Rosaria Purnomo[1], Agus Maman Abadi[2]
[1]Mathematics Education Department, Universitas Muhammadiyah Surakarta, Indonesia
[2]Mathematics Department, Yogyakarta State University, Indonesia
mega.eriska@ums.ac.id

Abstract**—**The purpose of this research was to produce instructional package in 7th grade on the 2nd semester with POGIL that consisted of lesson plans and student worksheets, which hadgood quality. The quality was determined based on Nieveen criteria, including validity, practicality, and effectiveness. This study was a development research. The developing model in this research was Plomp model, which consisted of preliminary research, development, and assessment phase. The research instruments were validation sheets, teacher assessment sheets, observation sheets for learning process, student assessment questionnaires, tests, questionnaires, and observation sheets for attitudes. The analysis of the validity and practicality of the data was done by converting the quantitative data in the form of assessment result score into the qualitative data in the form of five scale. The analysis of the effectiveness of the test results was conducted by determining the percentage of the students' learning mastery. The assessment of questionnaires and attitudes observation was conducted by determining the percentage of the students for each category. The result of the validation showed that the developed instructional package was very valid based on the lesson plans and student worksheets. The results of the tryout indicated that lesson plans and student worksheets were practical and effective. The instructional packagewas in the very practical category based on teacher's assessment and practical category based on the result of observation for learning process and students' assessment. The instructional package was also in the effective category based on students' learning mastery, questionnaires of religiosity, and questionnaires of attitudes.

Keywords: *competences in Curriculum 2013, development, instructional package, POGIL*

I. INTRODUCTION

The Curriculum 2013 is the newest curriculum in Indonesia which is publised as the recondition of Curriculum 2006. Through Curriculum 2013, the character and competences-based curriculum, Indonesian nationareexpected to become the dignified nation and its people have high competitivenesswith other people and nations in the world [1]. Mathematics learning process in Curriculum 2013 is focused on four competences. Those are religiosity, attitudes, knowledge, and skills.

One of the fundamental things that students can be successful in many areas of higher mathematics is to have automaticity in terms mathematical factual knowledge. Without the ability to retrieve facts directly or automatically, students are likely to experience a high cognitive load as they perform a range of complex tasks [2]. Thus, the factual knowledge becomes the basic knowledge that must be mastered by students in mathematics.

Moreover, several studies have documented that many students are having difficulty in understanding and applying concepts, finding relevance, trasferring skills within and across diciplines, and identifiying and developing the skills they need for success in specific courses [3]. One of the basic mathematical skills that must be possessed by the studentsisproblem solving skills [4].Unfortunately, research shows that students' ability to solve problems is far below their abilities to calculate [5].Mathematics learning process in the classroom do not give opportunities to students for investigating, reasoning, or deciding on the solution process and do not improve problem solving skills [6].

That condition causes a lot of junior high school students have not good achievement in mathematical knowledge and skills. This phenomenon can be seen from many students in 7th grade of SMP N 1 Yogyakarta still getmathematics learning mastery <75 in mid semester test, as shown in Table 1.

TABLE 1. MATHEMATICS LEARNING MASTERY THE 7TH GRADE STUDENTS OF SMP N 1 YOGYAKARTA IN MID SEMESTER TESTACADEMIC YEAR 2014/2015

Class	Percentage of mathematics learning mastery < 75	Percentage of mathematics learning mastery more than ≥ 75
VII A	65%	35%
VII B	37%	63%
VII C	66%	44%
VII D	83%	17%
VII E	77%	23%
VII F	66%	34%
VII G	74%	26%
VII H	32%	68%

Based on Table 1, there are still many students who have not yet achievedmathematics learning mastery≥ 75. It is required animprovement efforts in mathematics learning processto optimize the students' achievement in mathematical knowledge and skills.

Several studiesalso have documented that learning in schools only generates students with a lot of knowledge, yet they are lack of attitudes and skills. Many cases such as corruptions and anarchic actions show that Indonesiasociety isnot consistent with the religous and Pancasila values [7]. The research from [8] and [9] state that religiosity has an important role in the system of education and learning process. Thus, religiosity is an important part of the educational system in a country. Religiosity should not only developed through a religious education subjects, but also require the support of other subjects, including mathematics.

Some attitudes also need to be developed in mathematics learning process. Some attitudes that can be developed in mathematics learning process are confidence, curiosity, and responsibility. The research from [10] concludes that students with high academic achievement show higher level of self confidence than lower academic achiever students. The other research from [11] states that students with greater curiosity in more challenging schools have the greatest academic success. Otherwise, students with greatercuriosity in less challenging schools have the least academic success.

In Curriculum 2013, students should have the four competences in mathematics learning which uses scientific approach with implementation of inquiry learning [12].Unfortunately, many mathematics teachers are not yet able to implement the inquiry-based learning strategies which are appropriate with Curriculum 2013.The strategy which is frequently used by the teachers in mathematics learning process is expository or conventional learning.In addition, the teachers just focus on the students' cognitive domain during the process of learning mathematics.

By interviewingwith mathematics teachersin SMP N 1 Yogyakarta, Mrs. Sri Utami and Mr. Agus Margono on September, 8, 2014 state that the mathematics learning strategy which is frequently used in the class is expository or conventional learning which are focused on the development of students' cognitive domain. Mathematics teachers in SMP N 1 Yogyakarta are not yet able to implement the inquiry-based learning strategies which are appropriate with Curriculum 2013.

One of the learning strategies which are based on inquiry is Process-Oriented Guided Inquiry Learning (POGIL). It can be implemented in mathematics class as an alternative way to develop students' competences in Curriculum 2013. In a POGIL classroom, students work in a teamusing formal roles. The learning team constructs knowledge by working in a group with inquiry activities that has been specially designed in student worksheets [13]. These activities can improve the students' knowledge level by focusing on concept of development. Besides, the students can also apply their knowledge in new contexts. Moreover, the students learn to rely on thinking and performing skills rather than memorizing, and also developing positive relationships with other students [3].

The student worksheets in a POGIL classroom follow the learning cycle model which contains three parts i.e.: exploration, concept invention, and application [13]. Moreover, [13] explains that quiz becomes an important thing in POGIL class. Every period (except the first class period and the period after each hour exam) begins with a three-minute quiz. The purpose of the quiz is to give the teachers some immediate feedbacks about how well the concept is learned by the students, to reinforce the concept in the students' mind and to encourage the students to do the homework before the quiz is given.

Many POGIL classrooms employ formal roles. The roles are frequently rotated in every class meeting, so that every student experiences each role and responsibility. According to [3] and [13], the following are the most commonly used roles: 1) the manager;he/she actively participates, keeps the team focused on the task, distributes work and responsibilities, resolves disputes, and assures that all members participate and understand, 2) the spokesperson (presenter); he/she actively participates and presents reports and discussion result to the class, 3) the recorder; he/she actively participates, keeps a record of the assignment and what the team has done, and prepares a report in consultation with the others, 4) the strategy analyst (reflector); he/she actively participates, identifies strategies and methods for problem solving, observes and comments on group dynamics and behavior with respect of the learning process.

Furthermore, [3]explains that in a POGIL classroom, a teacher is not an expert that solely provides knowledge, but rather as a guide for students in the process of learning, developing skills, and their own understanding. The teacher role in POGIL classroom is as a facilitator who moves around the room observing every student group work. As a facilitator, teacher should observe and determine whether the problem is likely to be solved without intervention [13].

Thechallenge for teachers is to implement the inquiry-based learning strategies inmathematics learning process which are appropriate with Curriculum 2013. Because the implementation of Curriculum 2013 is a new things, the mathematics instructional package which are appropriate with Curriculum 2013 is still very limited. Interviewing with Mrs. Sri Utami and Mr. Agus Margono state that developing mathematics instructional package with POGIL that is oriented to the students' competences in Curriculum 2013 for 7th grade students on the 2nd semester has not been done by the teachers in SMP N 1 Yogyakarta. Therefore, it is necessary an effort to develop mathematics instructional package that enables students to actively construct mathematicalknowledge and skills through group interaction, has religious value and good attitudes.

Based on the background above, the formulation of the problem in this research is how the quality of mathematics instructional package with POGIL that is oriented to the students' competences in Curriculum 2013 for 7th grade students on the 2nd semester? Therefore, this research aims to produce and descibe mathematics instructional package with POGIL that is oriented to the students' competences in Curriculum 2013 for 7th grade students on the 2nd semester, consists of lesson plans and student worksheets which has validity, practicality, and effectiveness criteria [14]. Moreover, the benefits of this research are the teachers can use the mathematics instructional packagefor learning process in a classor in other school, help students to develop religiosity, attitudes, mathematical knowledge and skills, and repair and improve the quality of mathematics learning in school.

II. RESEARCH METHOD

A. *Design of The Research*

This research was development research. The developing model in this research was Plomp model which consisted of preliminary research, development, and assessment phase [15]. The product of this research was mathematics instructional package with POGIL for 7th grade on the 2nd semester which consisted of lesson plans and student worksheets.

B. *Procedure of The Research*

The identification and study aboutstudents'condition, mathematics learning processwhich took place in SMP N 1 Yogyakarta, Curriculum 2013, competences to be achieved by students, and the 7th grade mathematics materials on 2nd semester were conducted in the preliminary research phase. Furthermore, the preparation and design of the lesson plans and student worksheets were conductedin the development phase.The result fom this phase wasthe 1st draft of mathematics instructional package with POGIL. The formative assessment by experts was also conducted in this phase. Itaims to determine whether the 1st draft of mathematics instructional package whichhas been developed valid or not based on expert judgments. Then, tryoutabout mathematics instructional packagewhich has been valid based on expert judgments with the aims to test the practicality and effectiveness was conducted in the assessment phase.

C. Subject Tryout, Time, and Place of The Research

Tryout in this researchwas included the 1st and 2ndtryout. The 1sttryoutwas conducted only limited to a few students on Saturday, February 28, 2015 and aimed to obtain feedback from students as consideration for fixing LKS before it is implemented on learning in the classroom. Subject of the 1sttryoutwas nine students of class VII C SMP N 1 Yogyakarta, consists of three high-ability students, three middle-ability students, and three low-ability students. While the 2nd tryout was conducted on a class by implementing the instructional packagewhich was developed in mathematics learning process to determine the practicality and effectiveness of the instructional package. Subject of the 2nd tryout was students of class VII B SMP N 1 Yogyakarta, consists of 35 students. The implementation of instructional package which was developed in mathematics learning process was done as much as 8 times, 7 meetings for learning and 1 meeting to test and fill the questionnaires. The 1st meeting was began on Tuesday, March 17, 2015 and the 8th meeting was ended on Saturday, April 25, 2015.

D. Instrument, Data Collection andData Analysis Technique

The data in this researchwas data validation expert, teacher assessment, observation for learning process, student assessment, tests, questionnares, and observation for attitudes. The qualitative data was obtained from comments and suggestions on the development of instructional package. The quantitative data was obtained from the filling data collection instrument by giving the check mark (√) in the selection of an appropriate response.

Data collection techniques in this research was done by giving validation sheets, teacher assessment sheets, student assessment questionnaires,tests,questionnaires, and classroom observation through observation sheetsfor attitudesand observation sheets for learning process. Data collection instruments consist of validation sheets to measure the validity of instructional package, teacher assessment sheets, observation sheets for learning process, and student assessment questionnairesto measure the practicality of instructional package, then tests, questionnaires and observation sheetsfor attitudes to measure the effectiveness of instructional package.

Data analysis techniques used in this research: qualitative data in the form of comments and suggestions were analyzed qualitatively, then used as input for revising the products developed; quantitative data with a five-point scale is converted into qualitative data, with reference to the formula which was adapted from [16] in Table 2.

TABLE 2. DATA CONVERSION CRITERIA

Grade	Score Interval	Category
A	$X > \bar{x}_i + 1{,}5SBi$	Very good
B	$\bar{x}_i + 0{,}5SBi < X \le \bar{x}_i + 1{,}5SBi$	Good
C	$\bar{x}_i - 0{,}5SBi < X \le \bar{x}_i + 0{,}5SBi$	Pretty good
D	$\bar{x}_i - 1{,}5SBi < X \le \bar{x}_i - 0{,}5SBi$	Not quite good
E	$X \le \bar{x}_i - 1{,}5SBi$	Not good

Information:

$\bar{x}_i =$ mean ideal score = $\frac{1}{2}$ (ideal maximum score + ideal minimum score)

SBi = ideal standard deviation = $\frac{1}{6}$ (ideal maximum score–ideal minimum score)

X = total actual score

The instructional packagewas said to be valid if the validity which achieved minimum in the category valid. It was said to be practical based on teacher assessment if the practicality which achieved minimum in the practical category, based on the observation for learning process if the percentage of learning process reached at least 80%, and based on student assessment if the practicality which achieved minimum in the practical category. Moreover, it was also said to be effective if the results of the test on knowledge at least 80% of students in the class reached mathematics learning mastery ≥ 75, so did the test on skills.Also the results of questionnaires for religiosity at least 80% of students in the class reached a minimum height categories, and so did the questionnares for attitudes.

III. RESULT AND DISCUSSION

A. *Result of The Research*

The identification and study about the condition of the students wasconducted in the premilinary research phase. The results indicate that there were still many students of class VII SMP N 1 Yogyakarta getmathematics learning mastery < 75 in mid semester test as presented in Table 1. Thus, it was necessary an effortsto improve learning activities so that the achievement of students in mathematics learning mastery could more optimal. Implementation of POGIL in mathematics learning process could be used as an alternative way to provide meaningful learning experiences for students. It was hoped can optimize students' mathematics learning mastery related to knowledge and skills. In addition, students could also develop positive relationships with other students because in POGIL classstudentslearn actively through group interaction. This waspotentialto develop religiosity and attitudes of the students.

The identification and study about mathematics learning process in SMP N 1 Yogyakartawas also conducted in the premilinary research phase. Interviewingwith two mathematics teachersin SMP N 1 Yogyakartastate that the mathematics learning strategy which was frequently used in the class is expository or conventional learning which were focused on the development of students' cognitive domain. Mathematics teachers in SMP N 1 Yogyakarta were not yet able to implement the inquiry-based learning strategies which are appropriate with Curriculum 2013, that was POGIL. Moreover, the mathematics instructional package which were appropriate with Curriculum 2013 wasnot yet developed by the teachers in SMP N 1 Yogyakarta. So, developing mathematics instructional package which consistedof lesson plans and student worksheets with POGIL wasan alternative way for teachers to perform mathematical learning process which were appropriate with Curriculum 2013 easily.

Furhermore, the identification and study about Curriculum 2013 and competences to be achieved by studentswere also conductedin the premilinary research phase. The curriculum used in this research wasCurriculum 2013 which focused on four competences which consistsed of religiosity, attitudes, knowledge, and skills. The four competences that must be mastered by learners are need to be declared in such a way can be assessed as students' learning outcomes. Those become a reference from basic competences and should be developed in mathematics learning process. Then, based on the four competences and basic competencescould be developed indicators to determine the achievement of competences in this research.

The last in the preliminary research phase wasthe identification and study about mathematics materials on 7th grade on 2nd semester. Itwas conducted to identify, specify, and systematically compile the materials developed and tested in this research. The materials were consisted of rectangles and triangles, linear equality and inequalities in one variable and social arithmetic, transformation, and probability and statistics.

The next phase was development phase. In this phase, lesson plans and student worksheets weredesigned.Then, the experts conducted formative assessment to determine whether the 1st draft of mathematics instructional packagewhich have been developed valid or not. Lesson plans weredesigned and developed based on POGIL steps. Besides, the student worksheetswerealso designed and developed appropriate with characteristics of POGIL.

Lesson plans were developed based on Permendikbud Nomor 65 Tahun 2013 about standard process which explained the components that must be presented in the lesson plans. Those were school's identity, subjects' identity, grade/semester, subject matter, allocation of time, learning purpose, basic competences and indicator achievement of competences, learning materials, teaching methods, instructional media, learning resources, learning steps, and assessment of learning outcomes.Four lesson planswere prepared in the first draft. Lesson plans 1 were designed about rectangles and triangles for 10 meetings. Lesson plans 2 were designed about linear equality and inequalitiesin one variable and social arithmetic for 7 meetings. Lesson plans 3 were designed about transformation for 5 meetings. The last, lesson plans 4were designed about probability and statistics for 5 meetings too.

Four student worksheets were also developed in the first draft. Student worksheets 1 were designed about rectangles and triangles. Student worksheets 2 were designed about linear equality and inequalitiesin one variable and social arithmetic. Student worksheets 3 were designed about transformation. Student worksheets 4were designed about probability and statistics.

Each student worksheets was containedthe following elements: a description of the contents of student worksheets, useful to give an overview to the students about the material in student worksheets; instruction to use the student worksheets, useful to provide information on how to learn student worksheets; basic competences which to be achieved by students; concept maps; table of contents, useful to facilitate students in their search for the material to be learned; learning activities which consisted oflearning purpose, information, critical thinking questions, exercises, and assignments. The information contained little information about the material studied. Critical thinking questions aimed to help students found facts, concepts, principles, and procedures mathematics about the materials. The exercise useful to provide opportunities for students to apply what they found and apply what was found in the new situation, and also assignment contained homework for students.

The formative assessment was conducted by experts to see the contents of the 1st draft before it tested. Validation was done by providing the instructional package and validation sheetsfor two lecturer of Mathematics Education, in Yogyakarta State University and one mathematics teacher in SMP N 1 Yogyakarta. Based on the results of validation could be known the valid criteria for lesson plans and student worksheets. Table 3 below presented the formative assessment by experts to instructional package.

TABLE 3. VALIDATION RESULTS OF INSTRUCTIONAL PACKAGE

Instructional Package	**Total Empiric Score**	**Category**
Lesson Plans	366	Very valid
Student Worksheets	295	Very valid
Total	661	Very valid

Table 3 stated that each instructional packagewas in "very valid" category. It means that the initial product of instructional package has already usedin tryoutafter revision based on the suggestion from the experts.

The last phase was assessment phase. Tryout about mathematics instructional package was conducted in this phase. Tryout consisted of the 1st and 2nd tryout. The 1sttryout wasconducted only limited to a few students. While the 2nd tryout was conducted on a class by implementing the instructional package developed in mathematics learning.

Ideally, all mathematics instructional packagewhich have been developed must be tested. However, tryoutin this research did not test the entire instructional packageof class VII on 2nd semester which has been developed in the development phase, but only in the material aboutlinear equality and inequalitiesin one variable and social arithmetic. It was done because of limited time, cost, and energy. Nevertheless, it was believed that the entire mathematics instructional packagewhich has developed have similar results with mathematics instructional package which has been tested.

Student assessment as a results of the 1sttryout indicated that the display of student worksheets was attractive; the characters of text, images, and background on student worksheetswere suitable; the instructions to use student worksheets were clear; the language in student worksheets could understandeasily; the place to write answers on student worksheetswas sufficient; and the number of exercises on the worksheet was sufficient. However, there were some suggestions from students before it used inthe 2nd tryout.

The result of the 2nd tryout indicated that the instructional package was "very practical" based on teacher assessment. Data from teacher assessment about instructional package could be seen in Table 4.

TABLE 4. RESULT OF TEACHER ASSESSMENT

Instructional Package	Score	Category
Lesson Plans	59	Practical
Student Worksheets	70	Very practical
Total	129	Very practical

Then, the percentage of implementation learning processwas 96% and the percentage of implementation POGIL was 97%. This means that the instructional package could be said to be "practical" based on the observation for learning process. Moreover, mathematics learningprocess by using student worksheets developed could be said to be "practical" based on the student assessment. Data result of student assessment could be seen in Table 5.

TABLE 5. RESULTOF TEACHER ASSESSMENT

Rated Aspect	Score	Category
Attractiveness	827	Practical
Easiness	791	Practical
Usefulness	390	Practical
Total	2008	Practical

Classically, learning mastery for knowledge reached 80% and for skills reached 83% based on the resultof the tests. Moreover, the result of questionnaires for religiosity showed that 100% students were in the very high category. Then, the result of questionnaires for attitudes showed that 31% students were in the very high category and 69% students were in the high category.So, it couldbe concluded that the lesson plans and student worksheets were "effective" based on the result of tests and questionnaires.

B. Discussion

The planning process was required to facilitate the achievement of mathematics learning objectives in learning. It was the preparation of instructional package consists of lesson plans and student worksheets.The instructional package would facilitate the teacher to implement mathematics learning process.

Curriculum 2013 focused on four competences. Those were religiosity, attitudes, knowledge, and skills. Students should have those four competences in mathematics learning which used scientific approach with implementation of inquirylearning. One of the learning strategies which were based on inquiry learning and suitable with Curriculum 2013 is POGIL. It could be implemented in mathematics learning to develop the competences of students. In a POGIL classroom, students worked in a team. The learning team constructed knowledge by working in a group with inquiry activities that has been specially designed in student worksheet. These activities could improve the students’ knowledge level by focusing on concept of development. Besides, the students could also apply their knowledge in new contexts. Moreover, the students learned to rely on thinking and performing skills rather than memorizing, and also developing positive relationships with other students.

Therefore, it was neccessary to develop mathematics instructional package with POGIL to 7th grade on the 2nd semester that was oriented to the students’competences in Curriculum 2013. The mathematics instructional package developed consisted of lesson plans and student worksheets in material about rectangles and triangles, linear equality and inequalities in one variable and social arithmetic, transformation, and probability and statistics. While it was implemented in mathematics learning process only on material about linear equality and inequalities in one variable and social arithmetic.

The learning activities in the lesson plansconsisted of introduction, main activity, and closing. In introduction the teacher explained about the learning purpose,motivated the students to study the material, and gave prerequisite material to help student studying the related material apperception. Main activity was an activity that contained POGIL steps including organized the student into some groups consists of

4-5 students, explore, discover, apply what they have discovered, apply what they have discovered in new situations, presented the discussion result, and held a quiz. In the closing activitythe teacher asked the students to conclude the material which have been learned in that day, made a reflection to the learning process, gavehomework to the students and told the next materials that will be studied in the next meeting.

The student worksheets with POGIL designed contains learning cycle. The learning cycle was consisted of three important phases. Those were exploration, invention, and application. Exploration phase in student worksheet could be represented by a few of information about the materials.I n the invention phase, critical thinking questions were given to the students. Those questions guided the students to discover some facts, concepts, principles, and mathematics procedures. There were three kinds of critical thinking question which can be used. Those were directed, convergent, and divergent questions. Directed questions point the student to obviously discovered about the information. Convergent questions required students to synthesize relationships from their new discoveries (and previous knowledge) and lead to the development of new concepts or deeper conceptual understanding. Divergent questions were open ended and did not have unique answers (Hanson, 2006).In the application phase, the students woulddo some exercises to apply what they have discovered and new contextual problems.

Furthermore, based on the validation results could be known that the instructional packagedeveloped has achieved "very valid" category. It could be known from the results of the validation lesson plans and student worksheets. Based on the validation results could be concluded that the lesson plans were "very valid" and so did the student worksheets. That description showed that the instructional package developed was already use for tryout.

Moreover, based on the results of tryout in the classroom could be known that the lesson plans and student worksheets developed have achieved "practical" category. It could be known from the results of teacher assessment, observation for learning process, and student assessment. Based on the results of teacher assessment about the lesson plans and student worksheets after learning in the classroom could be concluded that the lesson plans and student worksheets were "very practical". Based on observation for learning process could be concluded that the lesson plans and student worksheetswere "practical” with the percentage of implementation learning processwas 96% and the percentage of implementation POGILwas 97%. Based on the results of student assessment could be concluded that the student worksheetswere "practical". That description showed that the lesson plans and student worksheets developed, POGIL learning activities couldbe done well.

Then, based on the results of tryout in the classroom could be known that the instructional package developedhasachieved "effective" category. It could be known from the results of tests, questionnaires of religiosity, and questionnaires of attitudes. Based on the tests results could be concluded that the instructional package was “effective”. Classically, learning mastery for knowledge reached 80% and for skills reached 83% based on the resultof the tests. Moreover, the result of questionnaires for religiosity shows that 100% students were in the very high category. Then, the result of questionnaires for attitudes shows that 31% students were in the very high category and 69% students were in the high category.That description showed that the instructional package developed could be an alternative way for supporting the achievement of the 7th grade junior high school students’competences in Curriculum 2013.

The result of this research supportedthe previous research that has been conducted by other researchers. The research from [17] stated that the students problem solving ability taught using POGILwas better than the students problem solving ability taught using expository in circumference and area of circle material. The other research from [18] stated that students’ mathematics achievement, process skill, and students’ activity passed through the minimal criteria by individually or classically in mathematics learning process by using POGIL in differential material. Moreover, the other research from [19] stated that the mathematical communication skill passed through the minimal criteria by classically has been implemented POGIL using manipulatives and based on etnomathematics. Besides, the students’ attitude towards culture was better than before. On the other hand, the result of this research also supported other development research from [20] stated that the pythagoras theorem instructional package such as syllabi, lesson plans and student worksheets with ideal approach assisted GeoGebra was valid, practical, and effective through 4-D developing model from Thiagarajan, Semmel, & Semmel.

Based on the description above, it could be concluded that the mathematics instructional package with POGIL that wasoriented to the 7thgrade junior high school students' competences in Curriculum 2013 on the 2nd semester has been proven validity, practicality, and effectiveness. Thus, the mathematics instructional package was consisted of lesson plans and student worksheets could use in the learning activity.

IV. CONCLUSION AND SUGGESTION

Based on the result of the research and discussion above, it can be concluded that the quality of mathematics instructional package with POGIL that was oriented to the 7th grade junior high school students' competences in Curriculum 2013 on the 2nd semester was valid, practical, and effective.

Some suggestion to the mathematics teachers, they can use mathematics instructional package with POGIL which has been developed in mathematics learning process because it has been valid, practical, and effective. It also can be used as a reference forthemto compile mathematics instructional package that is used to develop students' competences in the class. Futher suggestion for the researchers who are interested in development research can be develop mathematics instructional package in other materials, other attitudes variables, or for other grade levels.

The Development of Interactive Learning Media to Explore The Students' Mathematical Creative Thinking Ability

Nani Ratnaningsih
Mathematics Education of Siliwangi University
Tasikmalaya Jawa Barat
email: niratzk@gmail.com

Abstract - The purpose of this study was to design an interactive learning media, identify the beginning and end of the ability of creative thinking mathematical students, excavate student response to the implementation of media interactive learning, analyze the difficulties of creative thinking students. The method used were Research and Development, with the steps: identify of teaching material, organize media interactive learning, considered by the experts, try out media interactive learning and research instruments, examine the pre-test and post-test of mathematical creative thinking, implement of interactive learning media in Mathematics Capita Selecta course, distribute questionnaires and interviews. Data collection techniques included: media interactive learning test, mathematical creative thinking ability tests, questionnaires and interviews. The research instruments are mathematical creative thinking ability tests, questionnaires and interviews sheet. The population in this study were all students majoring in mathematics education semester of academic year 2015-2016. Sample used were cluster random sampling technique with 2 classes. The results showed that media interactive learning in Mathematics Capita Selecta course could be implemented. The pre-test showed that students' mathematical creative thinking was low, but the post-test showed that students' mathematical creative thinking performed in an medium level. Students' difficulties in mathematical creative thinking were on the flexibility and orginality indicators. In addition, students feel happy, challenged and motivated to learn in Mathematics Capita Selecta course.
Keywords: *Interactive Learning Media, mathematical creative thinking ability, difficulty thinking*

I. Introduction

Along with the demands of advanced science and technology, there are continuous efforts to improve the quality of education in Indonesia, especially in the field of mathematics education. Require new breakthroughs in curriculum development, human resources, learning and innovation in meeting the educational facilities. In connection with the development of human resources, the lecturer gives a very important role in providing supplies to students as future teachers through lectures. According to Festus (2013), the activity based-learning pedagogy is expected to make students feel responsible for their learning and support their own personal development. The use of instructional media is one way to lecturers so that students can understand the concepts that are presented, besides that lectures more interesting and fun so that students can learn more optimally. Various media that can be used in the lecture, including computer-based learning media or Information Technology (IT). Ali (2009) stated that one computer-based learning media is an interactive learning media, learning media is more interesting and the material is abstract can be visualized in animation media in accordance with actual conditions in the field, following the development of science and technology so that the motivation of students to learn and build knowledge becomes easier to do. One computer-based learning media that are popular today is an interactive medium. The use of interactive media in the learning of mathematics in the classroom is expected to attract interest and motivate students to improve their achievement. According to Kusuma (2009) in general, students have a high curiosity to try something new, including the technology in this decade is loved by teenagers and school children.

Lectures by using interactive learning media is one form of realization of the curriculum in Mathematics Education courses, so that students can learn actively on the Mathematics Capita Selecta course, understand the concepts and be able to develop creative thinking skills. Now, lectures on Mathematics Capita Selecta course already using computer-based learning media but only a powerpoint media that looks less

ISBN 978-602-74529-0-9

attractive and not interactive, so students seemed less motivated to learn. Currently each class at mathematics education department of Siliwangi University already available means to support computer-based learning. In this condition, the lesson should no longer be a tedious thing, as a few decades ago. Thanks to the development of information technology so rapidly, teaching materials can be presented with sounds and images are dynamic, not boring, as well as solid information. Therefore, the development of Information and Communication Technologies (ICT) based learning is expected to improve the quality of the learning process in the classroom. United Nations Educational Scientific and Cultural Organization (UNESCO, 2002) states that the use of ICT in learning has three objectives: to build a knowledge-based society habits like problem solving, communication skills, ability to find and manage information, turn information into new knowledge and share them with others, and to improve the effectiveness and efficiency of the process learning.

To foster the spirit of learning students, lecturers are required to create learning more interesting and innovative, so as to encourage the learn optimal learning and can develop the capacity to think. Efforts to create exciting and innovative learning and can facilitate develop creative thinking abilities, that is mathematics lectures using interactive learning media. Results of research Kusumah et al. (2008, 2009) and Wardani et al. (2013) that: a computer-based interactive learning can be presented in an interesting, efficient, and effective interaction patterns tutorials, simulations, or games; increase the ability of reasoning, communication, connection, problem solving, critical thinking, and creative thinking mathematically through learning computer media better than students in the regular classroom learning; implementation of the use of computer media can significantly increase positive attitudes and interests of students in learning mathematics.

Mathematical creative thinking ability toward Guilford model structure of human intelligence which consists of several factors including the operation of divergent product includes fluency, flexibility, and elaboration. Then Torrance (Hudgins et al., 1983) add components originality as a concept fundamental to the components of divergent thinking so that there are four components namely divergent thinking fluency, flexibility, elaboration, and originality. Evans (1991) suggested that components of divergent thinking: the problem of sensitivity is the ability to recognize the existence of a problem or ignore the misleading fact to recognize the real problem; Fluency is the ability to build a lot of ideas are easy; flexibility refers to the ability to build a diverse ideas; Originality is the ability to generate ideas that are unusual or extraordinary, solve problems in ways that are unusual or non-standard. Starko (1995) and Munandar (2004) suggests that the model structure of the intellect of Guilford is a model of intelligence complex, consisting of 180 components are formed through the combination of content, products, and operations. From the opinions above about divergent thinking of Guilford could conclude that line divergent creativity thinking. Understanding creativity according to Jones (1972) is a combination of flexibility, originality, and sensitivity. Hudgins et al. (1983) provide an understanding of creative thinking is a process that is productive in the sense that the creative thinking to produce a new idea or product.

This researh to design, develop and implement Adobe flash interactive learning media at Mathematics Capita Selecta Course to explore mathematical creative thinking ability. The purpose of this research: design, develop and implement interactive learning media at Capita Selecta Mathematics Course; evaluating the feasibility of interactive learning media based on expert assessment of materials and interactive media and empirical testing, measuring mathematical creative thinking abilities after using interactive learning media.

II. Research Methodology

This research is the depelovment with used Research and Depelovment method. The population are all students majoring in mathematics education semester of academic year 2015-2016. Sample used is cluster random sampling technique as much as 2 classes as many as 110 students. Instruments in this research: open questionnaire, a questionnaire is closed, and questions of mathematical creative thinking ability tests. In developing interactive learning media includes 4 stages: define, design, develop , and implementation. Each stage is explained as follows:

a. Stage define include: study literature, course material identification, analyze the characteristics of students, formulate learning objectives, and designing test questions mathematical creative thinking abilities. At this stage, analyze and identify all the needs required in designing interactive learning media and creative thinking abilities make about mathematics.

b. Stage design includes: the early design of interactive learning media and create questions test ability to think creatively about mathematics as much as 5. At this stage to make a preliminary draft media interactive learning using Adobe Flash program and about the mathematical creative thinking abilities will be tested.
c. Stage develop include: consideration of subject matter experts and media, data analysis and revision, instructional media and about the test results of the revision, the trial is limited to students, data analysis results of limited testing, test empirically, the feasibility of interactive learning media and about the test's ability to think creatively mathematics. At this stage, an evaluation by subject matter experts and media, limited trial against 9 students to see contant validity and face validity, then the empirical testing of students outside a sample of 30 people. The goal is to get advice and feedback to revise media interactive learning and creative thinking abilities about mathematics so that used in this research.
d. Stage Implementation includes: pretest, interactive learning media used in lectures, post-test mathematical creative thinking abilities, distributing questionnaires and interviews to students.

Interactive learning media assessment by experts include indicators: the type face used, operating instructions, menu navigation, completeness menu display, menu design overall, musical accompaniment, animated illustrations, color harmony, clarity and editorial images, use the button, and interactive. After media interactive learning and creative thinking abilities about mathematics is declared fit for use, and then implemented in the Mathematics Capita Selecta course during one semester. Each indicator broken down into several aspects of the measure. Scores of interactive learning media assessment rubrics as follows:

Table 1. Rubric Score Assessment Interactive Learning Media

Assessment Criteria	Score
Choose one of assessment criteria	1
Choose two of assessment criteria	2
Choose three of assessment criteria	3
Choose four of assessment criteria	4

Questionnaire for students include positive statement and negative statement. Selection positive statement: strongly agree (5), agree (4), disagree (2), strongly disagree (1) and negative statement: strongly agree (1), agree (2), disagree (4), strongly disagree (5). The ability to think creatively mathematical measure includes five indicators: sensitivity, fluency, flexibility, elaboration, and originality. The following rubric score mathematical creative thinking abilities.

Table 2. Rubric Score Assessment Mathematical Creative Thinking Ability

Number	Indicators	Aspect Measured	Score
1	Sensitivity	Did not answer or answered incorrectly	0
		Detecting deficiency and advantages of the problem but it is not clear	1
		Detecting deficiency and advantages of the problem but there is no mistake	2
		Detecting deficiency and advantages of the problem but not completely	3

		Can detect problems deficiency and advantages with complete and correct	4
2	Fluency	Did not answer or answered incorrectly	0
		Asking just one idea to solve the problem	1
		Propose various ideas solve the problem but there is a mistake	2
		Propose various ideas solve the problem but incomplete	3
		Propose various ideas solve the problem completely and correctly	4
3	Flexibility	Did not answer or answered incorrectly	0
		Solve the problem in only one way, but incomplete	1
		Solve problems with just one complete and correct way	2
		Solve the problem in various ways but incomplete	3
		Solve the problem by various means complete and correct	4
4	Elaboration	Did not answer or answered incorrectly	0
		Completing problem only small fraction	1
		Completing problem but there are still many deficiency	2
		Completing problem but less complete and clear	3
		Completing problems so complete and clear	4
5	Originality	Did not answer or answered incorrectly	0
		Solve problems by using standard formula	1
		Solve the problem in his own way but it is not clear	2
		Solve the problem in his own way but not yet completed	3
		Solve the problem in his own way and true	4

III. Results and Discussion

The validate interactive learning media, expert material selected 2 mathematics education lecturers and 2 lecturers computers, both criticism and suggestions, which are summarized as follows:

a. The material was as it should be delivered.
b. There are still some wording should be corrected, should be short, dense, clear and straightforward
c. Operating instructions and the flow should be more clear, systematic, logical and easy to understand; navigation menu is complete.
d. Less harmonious blend of colors should be more contrast, the look of each slide should be more interesting, interactive to be discreet in order to increase interest in learning and curiosity, backround more interesting and not boring, not too loud background music, interesting and appropriate.
e. Operating instructions presented in clear and unambiguous, straightforward, and easy to understand.

f. Should be from menu to menu; from one concept to another concept; from the beginning, middle and end should be interrelated.

Based on input and advice from subject matter experts and interactive learning media, then discuss with programmers to improve software interactive learning media. Once repaired, then validated again by the experts, so subject matter experts and media stated could be implemented. The following are examples of page views:

Figure 1. Examples of Display Interactive Learning Media

The next tested on 30 students who have already learned the 7th semester Capita Selecta Mathematics course previously tested but limited to 9 students representative of the ability of high, medium, and low to see the face validity and content validity. In general, the students argued against interactive learning software media that is semantically understandable, attractive colors, and display instructions are clear, but the time available is not sufficient. During the trial progresses, researchers observed the activity of students. Based on observations obtained some information: enthusiastic students using interactive learning software media, a discussion with a friend who was beside him, if anyone does not understand to ask. There are constraints experienced, some unresolved issues, but his time is up. Based on empirical testing, interactive learning media eligible for use in lecture.

Furthermore, an interactive learning media used in the course for 1 semester. Before to the implementation of interactive learning media in lectures, lecture held at the beginning of the pre-test mathematical creative thinking abilities against 110 students obtained a mean 12.21 from maximum score of 20 with the following results:

Table 3. Pre-test Results of Mathematical Creative Thinking Ability

Number	Criteria	Number of Students	Percentage (%)
1	Very High	2 Person	1.82
2	High	5 Person	4.54
3	Medium	10 Person	9.09
4	Low	93 Person	84.55
Sum		110 Person	100.0

After all the lectures is finished, then held the post-test mathematical creative thinking abilities obtained a mean 16.80 with the following results:

Table 4. Post-test Results of Mathematical Creative Thinking Ability

Number	Criteria	Number of Students	Percentage (%)
1	Very High	9 Person	8.18
2	High	27 Person	24.55
3	Medium	53 Person	48.18
4	Low	21 Person	19.09
Sum		110 Person	100.0

Furthermore further explored means on each indicator of the mathematical creative thinking abilities, with the following results:

Table 5. Means Post-test of Mathematical Creative Thinking Abilities In Every Indicators

Number	Indicators	Means
1	Sensitivity	2.9
2	Fluency	3.3
3	Flexibility	2.3
4	Elaboration	3.1
5	Originality	1.8

At the end of the course distributing questionnaires to students with the aim of asking in response to the use of this interactive learning media. The response of students to interactive learning media are summarized as follows:

a. The sentences short, dense, and clear; color interesting and not boring; can facilitate self-learning.
b. The procedure of the menu is clear and can be followed, helping to more easily understand the concept, but the time not enough.
c. The problem that is written is clear, but sometimes confused finish so curious to continue to finish.
d. The concept is found through the problem, and completion is full of challenges, linking with the previous concept.
e. Problems and questions provided are varied that no question of easy, moderate and difficult.

Student response to interactive learning media, problems experienced that time provided insufficient, the problems have not been resolved. Based on the results of the validation of the subject matter experts and interactive learning media, limited testing and test empirically the students, as well as the questionnaire to the student can be concluded that interactive learning media is feasible to implement in the lecture Mathematics Capita Selecta course for one semester though in terms of the time provided less adequate. This is because the software media interactive learning, facilitate students find the concept (not notified), lecturer just drive away. If students are having problems, not directly notified but was directed to use the referral question. Thus the automatic will invariably take longer than learning directly notified.

Noting the results table pre-test creative thinking abilities in classical mathematics students are at low criteria, although individually 2 students are at very high qualification and 5 students were in qualifying frequency. Achievement of this kind naturally, because the students have not been trained mathematical creative thinking. Based on the results of post-test that mathematical creative thinking ability students are at medium levels, meaning the ability to think creatively mathematics of students increased from a low level to medium although the increase is less significant. This is consistent with the results of research Kusuma (2009) and Wardani et al. (2013). Judging from the creative thinking abilities mathematical means every indicator, it can be concluded that the students had difficulty in orginality and flexibility indicators. Based on interviews on students, because thinking about orginality use that is not standard or common or not to use the formula, student difficulties in solving problems in their own way. Similarly, in a matter of flexibility, confused students solve problems in 2 ways. On two indicators, students are not familiar with how to solve the problem alone and in various ways. This is consistent with the results of research Ratnaningsih (2010), the results of research Patmawati dan Ratnaningsih (2015) that students have difficulty in mathematical creative thinking abilities in the indicator flexibility and originality. After the implementation of the post-test, students are given a questionnaire and conducted interviews to determine the interest of students to use interactive learning media in lectures. The results of questionnaires and interviews with media use interactive learning: learning interesting and fun, motivated and enthusiasm for learning, challenging, but the time available is not enough. Noting the results of pre-test and post-test, Interactive learning media is able to explore mathematical creative thinking abilities although the results have not been up.

IV. Conclusion

This research obtained conclusion: based validation experts and media interactive learning materials, empirical testing, and student responses through questionnaires and interviews that the design of interactive learning media could be implemented at Mathematics Capita Selecta Course. Mathematical creative thinking ability of students increased from a low level into a medium level. Students having difficulty in the ability to think creatively mathematical indicator flexibility and originality. Students get excited and motivated to learn using interactive learning media. Interactive learning media is able to explore creative thinking abilities mathematics although the results have not been up.

Guided Discovery:
A Method to Minimize The Tendency of Students' Rote-Learning Behavior in Studying Trigonometry

Naufal Ishartono
Department of Mathematics Education
Muhammadyah University of Surakarta
naufalishartono@gmail.com

***Abstract*—** In Indonesia, trigonometry is one of the topics that has been taught in senior high school level which contains a lot of formulas and concepts that have to be understood by the students. Formulas and concepts could be a cognitive burden for them, especially when the learning process does not involves them actively. So that, it will emerge a tendency for pupils to learn the formulas by rote. Teacher cannot take it for granted since this learning process will become meaningless. Therefore, Guided Discovery teaching method is considered to be needed as one of the alternative solutions to reduce the tendency of rote-learning behavior, since this method enables the teacher to engage students into a learning process of finding trigonometry formulas through reinvention steps provided by this method. In addition, this method require students' prior knowledge along the reinvention process, so that the learning process becomes more meaningful. The purpose of this article is to describe the implementation steps of Guided Discovery method in trigonometry learning process to minimize students' rote-learning behavior. The method used in this paper is literature review. This paper will explain the theories of Guided Discovery, rote-learning behavior, and how the method will minimize the learning behavior.

Keywords: *guided discovery, rote-learning behavior, trigonometry*

I. INTRODUCTION

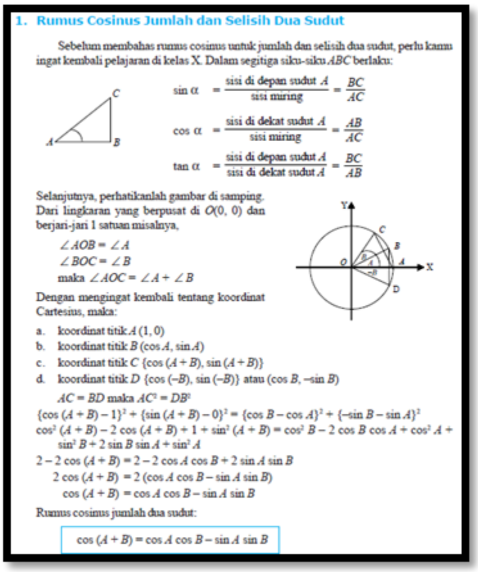
Trigonometry is a branch of mathematics that concerns on the elements of triangle such as sinus, cosine, tangent, secant, cosecant, cotangent, and its applications [1]. Many concepts are developed from these elements to enable people in solving their daily-life problems, namely in a construction, in music, in economy, and etc. Therefore, we believe that trigonometry need to be understood as early as possible by the people, especially in high school level. In Indonesia, based on curriculum of 2013, topic of trigonometry is formally taught in senior high school level. At grade X Science Program, the students learn the topic of ratios, functions, equations, and identities of trigonometry. While for topics of trigonometry derivative formulas and its uses are taught at grade XII Science Program.

Specifically in the topic of trigonometry derivative formulas and it uses, the students will learn at least 25 formulas which whatsoever the way they have to understand these, plus the concepts and formulas that they have to remember when they learned this at grade X. Exactly, the demand to understand and to remember those number of formulas and concepts will be not easy for the pupils. So that, it emerges a tendency of the students will learn it by rote since this is the easiest way to put any information into their brain. This tendency appeared because some factors including the teacher factor, the student factor, and the learning resource factor.

From the teacher factor, the tendency can be caused by the way teacher explains, teaches, and delivers the material. There is a possibility the teacher uses a direct teaching method in explaining the way to find the formulas without giving any chance for the students to get involve during the learning process. From the student factor, as we mentioned before, it can be due to the cognitive burden arises in their mind when they are obliged to understand and to remember all of the concepts and the formulas, so they tend to use rote learning method to ease the way they understand the materials. While from the aspect of learning resources, a lot of mathematics books provided in bookstores merely give constructed steps without allocating any space for the students to be engaged in the process of finding the formulas. We can figure

ISBN 978-602-74529-0-9

this condition out by observing the following samples of Indonesian Mathematics Electronic School Book (ESB):



1. Rumus Cosinus Jumlah dan Selisih Dua Sudut

Sebelum membahas rumus cosinus untuk jumlah dan selisih dua sudut, perlu kamu ingat kembali pelajaran di kelas X. Dalam segitiga siku-siku ABC berlaku:

$$\sin\alpha = \frac{\text{sisi di depan sudut } A}{\text{sisi miring}} = \frac{BC}{AC}$$

$$\cos\alpha = \frac{\text{sisi di dekat sudut } A}{\text{sisi miring}} = \frac{AB}{AC}$$

$$\tan\alpha = \frac{\text{sisi di depan sudut } A}{\text{sisi di dekat sudut } A} = \frac{BC}{AB}$$

Selanjutnya, perhatikanlah gambar di samping. Dari lingkaran yang berpusat di $O(0, 0)$ dan berjari-jari 1 satuan misalnya,

$\angle AOB = \angle A$
$\angle BOC = \angle B$
maka $\angle AOC = \angle A + \angle B$

Dengan mengingat kembali tentang koordinat Cartesius, maka:

a. koordinat titik A $(1, 0)$
b. koordinat titik B $(\cos A, \sin A)$
c. koordinat titik C $\{\cos(A+B), \sin(A+B)\}$
d. koordinat titik D $\{\cos(-B), \sin(-B)\}$ atau $(\cos B, -\sin B)$

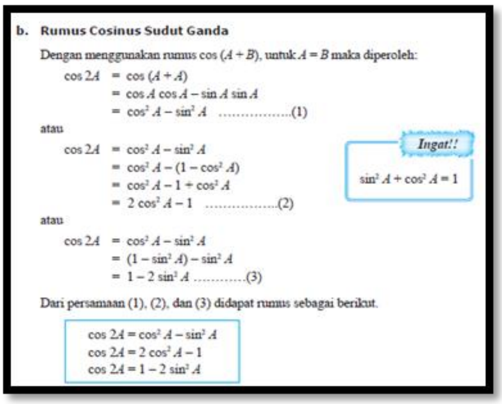
$AC = BD$ maka $AC^2 = DB^2$

$$\{\cos(A+B)-1\}^2 + \{\sin(A+B)-0\}^2 = \{\cos B - \cos A\}^2 + \{-\sin B - \sin A\}^2$$
$$\cos^2(A+B) - 2\cos(A+B) + 1 + \sin^2(A+B) = \cos^2 B - 2\cos B\cos A + \cos^2 A + \sin^2 B + 2\sin B\sin A + \sin^2 A$$
$$2 - 2\cos(A+B) = 2 - 2\cos A\cos B + 2\sin A\sin B$$
$$2\cos(A+B) = 2(\cos A\cos B - \sin A\sin B)$$
$$\cos(A+B) = \cos A\cos B - \sin A\sin B$$

Rumus cosinus jumlah dua sudut:

$$\boxed{\cos(A+B) = \cos A\cos B - \sin A\sin B}$$

FIGURE 1. THE SAMPLE OF ESB IN FINDING THE FORMULA OF COS (A + B)



b. Rumus Cosinus Sudut Ganda

Dengan menggunakan rumus $\cos(A+B)$, untuk $A = B$ maka diperoleh:

$$\cos 2A = \cos(A+A) = \cos A\cos A - \sin A\sin A = \cos^2 A - \sin^2 A \quad \ldots\ldots(1)$$

atau

$$\cos 2A = \cos^2 A - \sin^2 A = \cos^2 A - (1-\cos^2 A) = \cos^2 A - 1 + \cos^2 A = 2\cos^2 A - 1 \quad \ldots\ldots(2)$$

Ingat!!

$\sin^2 A + \cos^2 A = 1$

atau

$$\cos 2A = \cos^2 A - \sin^2 A = (1-\sin^2 A) - \sin^2 A = 1 - 2\sin^2 A \quad \ldots\ldots(3)$$

Dari persamaan (1), (2), dan (3) didapat rumus sebagai berikut.

$$\boxed{\begin{aligned}\cos 2A &= \cos^2 A - \sin^2 A\\ \cos 2A &= 2\cos^2 A - 1\\ \cos 2A &= 1 - 2\sin^2 A\end{aligned}}$$

FIGURE 2. THE SAMPLE OF ESB IN FINDING THE FORMULA OF COSINE 2A

When we observe the figures above, the book directly gives the way to find the formulas, then emphasizes it by "boxing" the formulas. The first concern is, as an appropriate textbooks in general, this book does not involve student participation in finding the formula in question. The next concern is the box sign given on the formulas that giving a possibility for the students to pay their attention not on the process of finding the formula, but straightly on the formula. So that if the students want to memorize the formulas, this book indirectly "facilitates" them by pointing some important parts to be memorized, when in this case is the formulas. From those concerns, this can be seen that the available learning resource still less engaging the pupils actively during the learning process of finding trigonometry formulas. Therefore, the tendency of rote-learning will be inclining.

Basically, rote learning is the easiest way to take an update of what we learn. However, the information learned by the students will be easily forgotten since there is nothing "memorable" left in their mind. Hence, the learning process will become meaningless. Ausubel in [2] says, "…if the learner's intention is to memorize it verbatim, i.e., as a series of arbitrarily related word, both the learning process and the learning outcome must necessarily be rote and meaningless". By relating to Indonesian Curriculum 2013, rote-learning behavior does not support the aim of this curriculum which is the learning process of curriculum 2013 should be *to get to know*, not *to be told*. This means, in the purpose of making the class becomes less rote learning but more meaningful, so the students should be actively finding out new information using their cognitive skill and prior knowledge, not in the opposite way.

Hence, we need a teaching method to minimize the students' tendency of memorizing the material they have learned so that the learning becomes more meaningful. The method should be able to engage the pupils actively in the process of constructing trigonometric derivative formulas. Therefore, they can experience the same condition as when the formulas were invented for the first time. This experience will be memorable in the minds of the students where they understand the way the formula was constructed. So when one day they forgot the formula they have learned, they will be able to reconstruct these formulas with the memory that sticks in their minds. Therefore, one of the teaching method that is appropriate to this condition is Guided Discovery teaching method. Guided Discovery is a teaching method that can involve the students actively to find new knowledge based on their prior knowledge under the guidance of the teacher. Through this method, the student involvement in finding the trigonometric formulas will be accommodated properly.

Based on the description of the background above, this paper offers a Guided Discovery teaching method in minimizing the tendency of students' rote-learning behavior in studying trigonometry. The aim of this paper is to explain the theories of Guided Discovery, rote-learning behavior and the way this method minimize the tendency of rote-learning behavior theoretically. The method used in this paper is literature rivew.

II. THEORITICAL FRAMEWORK

A. *Guided Discovery*

Before we discuss guided discovery teaching method, we need to explore the essence of this teaching method. Based on the history, [3] state that the first example of Discovery method was given by Plato about the dialogue between Socrates and a young slave where by the time this method is known as Socratic Method. According to Bruner in [3], he says, "discovery is a process, a way of approaching problems rather than a product or particular item of knowledge". In a short words, we can say that learning by discovery is learning to discover, where the students face a problem and they will find the way to solve it. According the definition [4], "Discovery learning is intentional learning through supervised problem solving following the scientific method of investigation". Whereas according to [5], "Discovery learning is hands-on, experiential learning that requires a teacher's full knowledge of content, pedagogy, and child development to create an environment in which new learnings are related to what has come before and to that which will follow". If we drag a correlation based on the three experts (Bruner, Moore, and Abruscato) statements, then we can conclude that Discovery learning is a learning process through a process of problem solving that is arranged from investigation steps to discover new information or skills for the students.

Furthermore, Moore explains that Discovery learning can be done in three steps, depends on the solution to the problem. First, a discovery that is guided carefully (Guided Discovery). Second, a discovery that is guided accordingly (Modified Discovery). Third, a discovery that is limited only on a supervision (Open Discovery). Since our focus only on the high school students ability, so the level of Discovery learning that is chosen to be discussed is Guided Discovery.

According to [6], "Guided Discovery was the name to hand-on activities and laboratory investigation that led the learner to a predetermined or a predictable data set or response". While [7] says that Guided Discovery is a teaching method based on inquiry, a constructive teaching theory within a problem solving situation where the student use their prior knowledge and experiences to find facts, correlations, and truths to be learned. Hence, based on the two experts' statement we can draw a conclusion that Guided Discovery method is a method to direct students to construct their knowledge through a discovery of new concepts and knowledge under teacher guidance.

As a teaching method, exactly Guided Discovery has advantages and disadvantages. The following table will mention some of them according to Marzano in [8]:

TABLE 1. ADVANTAGES AND DISADVANTAGES OF GUIDED DISCOVERY METHOD

Advantages	**Disadvantages**
1. Students will actively participate during the learning process. 2. Instill well as foster an attitude of inquiry. 3. Support students' problem-solving	1. Not all of the students can follow the lessons in this way since some of them are still familiar and easily understood by the lecturing method. 2. Not all topics are suitable delivered with

skill. 4. Provide a space for interaction among the students, as well as students to teachers, in order to train the students to communicate their idea properly and correctly. 5. The subject being studied can achieve a high level of capability and longer lasting because the students are involve to find new knowledge.	this method. Generally, topics related to the principles of the model can be developed with Guided Discovery.

Besides the advantages and the disadvantages, we also can find cognitive benefits for the students by implementing Guided Discovery teaching method in class. Here are some of them [9]:

1. It encourages analytic learning.
2. It exploits learners' cognitive skills.
3. It improves critical thinking skills.
4. It involves students in problem solving tasks.
5. It helps learners become aware of and articulate their mental process.
6. Learner actively in the learning process.
7. Learners understand and remember better what they have work out for themselves.

Indeed, this method has main objective in term of developing students' capability i.e. according to [10], "The prime objective of these (guided discovery) activities is to have students discover, and/or self-construct, the scientific/technological concept embedded in the activities as students do the activities'. In addition in the same page, [10] reminds us that although this activity has been in the design as much as possible, there will be students who do not follow the lesson plan that has been designed by the teacher. Thus, the teacher has to be flexible during the learning process. Here are the steps of Guided Discovery teaching method [11]:

1. Teacher determines the task criteria such as giving problems. Then the students find solutions for the problems. The problem that has been given should contain clues about things students need to do, namely students find the solutions of the problems by themselves.
2. Smart students will have possibilities to find the answer by themselves without teacher's guidance. Otherwise, students who incapable to find the answer need to have their first guidance by the teacher. This guidance should be in form of simple questions.
3. Having first guidance, the students who able finish the problem should check their answer by using the provided data. While for the student who cannot find the answer, they get second guidance by the teacher. The guidance is in form of questions to arrange the data that already available. The aim of this guidance is to get samples of the answer from some of the provided problems.
4. After the second guidance has already given, the students who succeed getting the answer of the provided problems should check their answer using the data that already exist. The students who do not able to find their answer get the third guidance from the teacher which in form of additional data that is arranged into a list. The expected goal of this third guidance is to make students can find the answer. If by giving this additional data the student do not find the answer yet, the teacher have to give another short guidance verbally for the students to get the expected answer right away.
5. Students are required to check their answer after they get their third guidance.
6. After they check their answer, they use it to finish the task criteria.
7. Students find the answer from what they do in task criteria.
8. The answer from the task criteria is still conjectural, so a proof is needed to verify it. So the teacher must give the answer a confirmation whether the students are correct or not.
9. Teacher gives enrichment to the students in form of applicable problems. It is expected in solving the problems, they can use the concept they just have got.
10. If the student can answer the problems correctly, so it can be said that they succeed constructing new knowledge about a concept that they have learned.

While according to Soedjadi cited in [11], says that there are 6 steps that need to be done to complete a learning by Guided Discovery method:

1. Giving Problem
   Students required to understand the given problem.

2. Data Development
   Students required to seek or pointing the possibilities other data as the continuity of the known data.
3. Data Arrangement
   Students required to arrange the data obtained for the first step and second steps in a list.
4. Extra Data
   Students required to add extra data as the continuity of the known data if the expected pattern is not obtained yet.
5. Answer The Problem
   Students answer the problem in the first step.
6. Checking The Answer
   Students required to see the truth of the general pattern that is obtained with some available data.

In this instructional method, the teacher becomes a facilitator, who guides students in the right directions so as to avoid misunderstanding of the rules. Hence, there are some things that must be considered during the use of this method in the learning process, as outlined by Michael Swan [9].

1. The rules should be true.
2. The rules should show clearly what limits are on the use of a given form.
3. The rules need to be clear.
4. The rules ought to be simple.
5. The rules need to make use of concepts already familiar to the learner.
6. The rules ought to be relevant.

B. Rote-Learning Behavior

The definition of rote learning is a learning by memorizing information repeatedly [12]. The idea of this method is the more we repeat the information, the more information we will remember in verbatim. Experts generally agree to a certain point that rote learning is necessary and important. This method is commonly used when fast retention is required, such as memorizing phone number, someone’s name, or post number. Or in education, when students need to remember the alphabets and how to spell the words.

Indeed, there must be pros and cons about the use of this method. For the cons, some believe that by having rote-learning method as a way to learn new information, some students may forget the facts that they have learn after doing test, and may not full understand the concepts to begin with [13]. For instance, when students are studying about trigonometric formulas for the sake of a test on the next day, whereas they did not study well before, so they realize that they need to remember all formulas in a short time. They will probably not have a very deep understanding of the actual meaning of the formulas. They will then likely forget all the other facts shortly anyway.

In the other hand, some pros believe that rote learning method will build the foundation, so students can learn more difficult concepts. For example, firstly students have to acknowledge the shape of triangle, square, trapezium, and circle, then they begin to find area of those shapes.

According to [14], the revised taxonomy includes six cognitive process categories, one most closely relates to retention (Remember) and the other five relates to meaningful learning (Understand, Apply, Analyze, Evaluate, and Create). This means that when the learning process merely focus on memorizing the material, so this will become meaningless.

C. Trigonometry in Senior High School

Based on Indonesian curriculum of 2013, topic of trigonometry has been taught at grade X and grade XII natural science program. At grade X, students will learn about angle, degree, radian, quadrant, ratios (sinus, cosine, tangent, cotangent, cosecant and secant) and trigonometry identities. While at grade XII natural science program, students will learn compound angles formulas, double-angle and half-angle formulas, multiplication formulas for sinus and cosine, addition and subtraction formulas of sinus and cosine. Those materials are formulated into basic competences presented as follows:

TABLE 2. BASIC COMPETENCES OF TRIGONOMETRY BASED ON CURRICULUM OF 2013

Grade	Basic Competences
X	3.15 Understanding the concept of trigonometric ratios in right-angled triangle through the investigation and discussion about the ratios of corresponding sides in some congruent right-angled triangles. 3.16 Determining the properties and relationship among trigonometric ratios in a right-angled

	triangle. 3.17 Understanding and determining the relation of trigonometric ratios from an angle in every quadrant, choose and implement it to solve problems in mathematics. 3.18 Understanding the concept of trigonometric function and analyze its graphic function as well as determining the relation of value of trigonometric function from special angles. 4.15 Applying trigonometric ratios to solve problems. 4.16 Presenting trigonometric graphic function.
XII	3.6 Describing the identity of sinus summation, identity of sinus subtraction, identity of cosine summation, identity of the different to be implemented in problem solving. 4.6 Presenting and analyzing the identity of sinus summation, identity of

III. DISCUSSION

As what has been described before, in which rote-learning is a method of learning that can lead students to a meaningless learning process, it is good if we discuss the definition and conditions of meaningful learning before we discus much about how the method of Guided Discovery can be an alternative solution in minimizing the tendency of rote learning.

Meaningful learning always be related to Ausubel, a psychologist who advance a theory which contrasted meaningful learning from rote learning. He believes that learning of new knowledge relies on what is already known [15]. This means that in order to construct new knowledge, it is required students' prior knowledge in order they can easily relate this new knowledge with what is already familiar in their minds. So that, the new knowledge will stick around longer in students' minds. Next, Piaget in his theory of cognitive development suggested that human's unable automatically understand and use information that they have been given because they need to construct their prior knowledge through prior personal experiences to enable them to create mental image [15]. Where in a short words, he says that human learn by constructing their own knowledge. Therefore, to construct a prior knowledge through prior personal experience, students need to be involved actively during the learning process. Because when they solely memorizing the material, they do not make any way to relate what they have known to what they going to know.

Following table explains the different between meaningful learning and rote learning according to Ausubel [16]:

TABEL 3. MEANINGFUL LEARNING CONTRASTED WITH ROTE LEARNING

Meaningful Learning	**Rote Learning**
1. Non-arbitrary, non-verbatim, substantive incorporation of new knowledge into cognitive structure.	1. Arbitrary, verbatim, non-substantive incorporation of new knowledge into cognitive structure.
2. Deliberate effort to link new knowledge with higher order concepts in cognitive structure.	2. No effort to integrate new knowledge with existing concepts in cognitive structure.
3. Learning related to experiences with events or objects.	3. Learning not related to experience with events or objects.
4. Affective commitment to relate new knowledge to prior learning.	4. No affective commitment to relate new knowledge to prior learning.

If we associate it with topic of trigonometry taught in schools, the formulas and concepts being taught is easy to "rediscover" by the students. This is because students already have their prior knowledge enough to find those formulas and concepts. For instance, in the material of trigonometric ratios in right-angled triangle at grade X, students already studying the properties of right-angled triangles earlier when they were in junior high school. So as to introduce the concept of sine (as a comparison of the length of front side of the corner and the hypotenuse of right-angled triangle), or cosine (as the length ratio of the next side of the corner and the hypotenuse of right-angled triangle) can be done easily. Another example, the material of trigonometric derivative formulas to formula of sin $(\alpha \pm \beta)$ which can be found easily using the trigonometric formula to determine the area of any triangle they have learned at grade X. Therefore, it is very unfortunate if students only know (by memorizing process) without understanding the meaning and the origins of the trigonometric formulas and its concepts. The impact is that when they are oblivious to these formulas they cannot re-construct these formulas, or they merely know the formulas and concepts but they cannot use it to solve problems. So, meaningful learning is a must in studying trigonometry by the students.

Based on those reasons, Guided Discovery is considered to be an alternative solution to lead the learning process into a meaningful learning process by minimizing the tendency of students learn by rote. This is because:

1. Guided Discovery addresses some of the drawbacks associated with both deductive and inductive instruction as it is essentially learner-centered. With the combination of inductive-deductive instruction, this will encourage analytic learning and students' cognitive skills will be exploited.
2. It makes learning memorable since learners are actively involved in the process, so the material will be long lasting in their mind.
3. It is meaningful because it involves learners' own reasoning. With this, they can reconstruct the trigonometric formulas whenever they forget the formulas or whenever they will use it to solve problems.

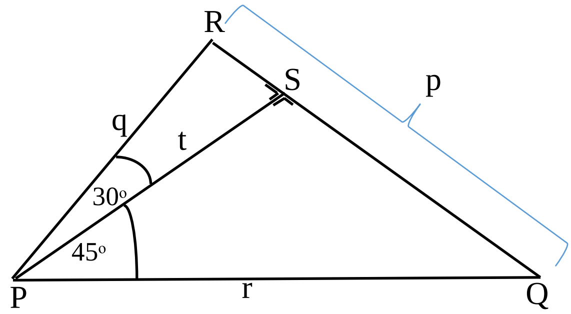
From two version of Guided Discovery presented before, Hirdjan's steps of Guided Discovery is considered to be preferred to Soedjadi's steps as his steps are more flexible. This means in the Guided Discovery steps we may provide some loops in some steps. For example, in Hirdjan's steps, for some smart learners or for them who able to finish the first steps may skip the second and the next steps. Therefore, the Guided Discovery steps using in this paper is an adoption from Hirdjan's steps of Guided Discovery teaching method. As a result of the modifications are as follows:

1. Giving Problems
   The teacher gives a problem, and learners seek resolution of the problem. The given problem should contain clues to the direction and the objectives about what they have to do. Such as they find the solution by themselves from the given problem.
2. Development of Data
   In this phase, students are required to find/pointing to the possibility of other data as a continuation of the data that is already known. Students who are smart enough will finish the problem without guidance. Otherwise, they will get a guidance in the form of developed questions from the simplest way.
3. Data Preparation
   In this phase, teacher guides the students by giving them a more specific ways to find the formula using the data in step 1 and step 2. This way is in form of the steps to find the formula, but not in a general way.
4. Extra Data
   Teacher gives students extra data that will direct them to the targeted formula. It is expected that with this guidance, students can determine the formula.
5. Verification
   In this step, the students are required to verify the formula they have found by themselves. If the verification is correct, so they can continue to the next step. Otherwise, they need to recheck their work in the previous step, or they can consult with the teacher of their friends who already finish their work correctly.
6. Application Exercises
   Teacher gives the students some problems, and it is expected that they do the problems use the formulas they found.

The followings are the sample of using the modification steps in finding the formula of sin $(\alpha \pm \beta)$:

1. Giving Problems
   In this step, students are given a question whether the students are able to determine the value of sin $(\alpha + \beta)$ and sin $(\alpha - \beta)$ by providing a reason or an explanation. If they sure with their answer, they may continue to the step of Verification with a condition if they have a problem, they have to back to the second activity. But if they do not find the problem, they may continue to the last step.
2. Development of Data
   Students get a guidance in the form of new data by letting α and β in the form of numbers such as "let $\alpha = 45°$ and $\beta = 30°$, is it true if sin $(\alpha + \beta) = \sin 75°$? And is it true if sin $(\alpha + \beta) = \sin 15°$?". If the students are able to answer those question, so they may continue to the verification phase. Otherwise, they have to continue to the third steps.
3. Data Preparation
   The sample of this step can be seen in the following illustration:

ISBN 978-602-74529-0-9



Use the trigonometric formula to find the area of triangle to determine the area of ΔPRS, ΔPQS, dan ΔPQR.

Area of ΔPRS = ……………………. (i)

Area of ΔPQS = ……………………. (ii)

Area of ΔPQR = ……………………. (iii)

From the figure above, you can determine:

In ΔPRS, cos 30º = $\frac{t}{q}$, t = ...(iv)

In ΔPQS, cos 45º = $\frac{t}{r}$, t = ...(v)

Substitute equation (v) to equation (i), and substitute equation (iv) to equation (ii):

Area of ΔPRS = ……………………. (vi)

Area of ΔPQS = ……………………. (vii)

Use the equation of (iii), (vi), and (vii) to determine the formula of sin (a + b) and sin (a - b) with given:

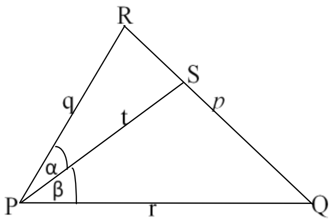
Area of ΔPQR = area of ΔPQS + area of ΔPRS
.... = ...
sin 75º = sin (45º + 30º) = ...

With the same way, you can determine the value of:
sin 15º = sin (45º - 30º) = sin (45º + (-30º) = ...

Can you determine the value of sin (a + b) and sin (a – b)? If yes, go to step 5. If not, continue to the next step.

4. Extra Data
The sample of this step can be seen in the following illustration:

Let a = α and b = β, then observe the following figure:



Use the trigonometric formula for area of triangle and determine the area of ΔPRS, ΔPQS, and ΔPQR.

Area of ΔPRS = ……………………. (i)

Area of ΔPQS = ……………………. (ii)

Area of ΔPQR = ……………………. (iii)

From the figure above, you can also determine:

In ΔPRS, cos α = $\frac{t}{q}$, t = ...(iv)

In ΔPQS, cos β = $\frac{t}{r}$, t = ...(v)

Substitute the equation (v) to (i), and substitute equation (iv) to (ii):

Area of ΔPRS = ……………………. (vi)

Area of ΔPQS = ……………………. (vii)

Use equation of (iii), (vi), and (vii) to determine sin (a + b) and sin (a - b) with given:

Area of ΔPQR = area of ΔPQS + area of ΔPRS

.... = ...

Sin ($\alpha + \beta$) = ...

As you already determine the formula of sin (α + β), then determine the formula of sin (α - β) using the formula of sin (α + β) that you have found by considering that $\alpha - \beta = \alpha + (-\beta)$.

sin (α – β) = sin (α + (– β))

= …………………………………………

sin (α – β) = …………………………………………

Remember:
cos (–α) = cos α
sin (–α) = –sin α

Of course you have found formula of sin (a + b) and sin (a – b). Then you may continue to the next step.

5. Verification

   Students are required to rewrite the formula of sin (a + b) and sin (a – b) they have found. Then they have to find the value of sin (a + b) and sin (a – b) if given a = 30º dan b = 30º, so they are able to prove whether the formula they have found is correct or not which is seen from its calculation. Because for sin (a + b) = sin 60º = $\frac{1}{2}\sqrt{3}$, while for sin (a – b) = sin 0º = 0. If their answer is correct, so they can continue to the sixth step, otherwise they can discuss to their friend until they get the right answer.

6. Application Exercises

   Teacher can provide them some enrichments such as find the value of sin 125º, sin 15º, etc.

CONCLUSION

Trigonometry as a branch of mathematics plays a big role in assisting people solve their problem, such as in economy, technology, architecture, music, etc. That makes experts believe that trigonometry must be taught as soon as possible especially in school, so that students can get to know the application of trigonometry earlier. Hence, in the process of learning trigonometry, the meaningfulness of this learning should be prioritized so that students' understanding can be more comprehensive. Guided Discovery teaching method is chosen in this paper as an alternative solution to support this condition since this method prioritizes students' involvement and reasoning ability during the discovery process of trigonometric formulas, thus material will be long lasting in their minds and become more meaningful. So that, the possibility of students choose rote learning will be minimized.

The Effect Of CTL Approach With Talking-Chips Setting On Mathematical Communication Of Junior High School's Students

Nina Agustyaningrum
Mathematics Education Department, Faculty of Teacher Training and Education
Universitas Riau Kepulauan
Batam
agustyaningrum@gmail.com

Abstract**—** The purpose of this study was to describe the effect of contextual teaching and learning (CTL) approach with talking chips type cooperative setting on junior high school student's mathematical communication. This study was a quasi-experimental research whose population was all the 8th graders in SMP Negeri 3 Sleman that consisted of six classes. From the six classes, class VIII A and VIII B were randomly selected as the sample. Class VIII A as the experiment group dealt with CTL approach in talking chips type cooperative setting, while class VIII B as the control group dealt with conventional learning approach. The instrument used to collect the data was mathematical communication test. The results of the study using Independent Sample T-test in 5% significant level, showed that the CTL approach in cooperative setting of talking chips type has an effect on student's mathematical communication in SMP Negeri 3 Sleman. For further, it can be concluded that the CTL approach with talking chips type cooperative setting is better than the conventional learning approach in terms of developing student's mathematical communication in SMP Negeri 3 Sleman.

Keywords: *contextual teaching and learning, mathematical communication, talking chips*

I. Introduction

Mathematics is a part of the science aspects which its application widely used in various fields. In the appendix explanation of National Education Minister Regulation Number 22 in 2006 mentioned that the rapid development in the field of information and communication technology today is based on the mathematical development in the field of number theory, algebra, analysis, probability theory, and mathematical discrete. In the appendix was also mentioned that in addition to a focus on mathematics learning achievement, one of the goals of mathematics learning is that students have the ability to communicate ideas with symbols, tables, diagrams, or other media to clarify the situation or problem. This is referred as mathematical communication.

Based on Depdiknas (2003, p. 12) mathematical communication is a students' skill to express and interpret mathematical ideas orally, in writing or demonstrating what is in mathematical problem. On other hand, Principles and Standards for School Mathematics (NCTM, 2000) stated that "if the students have good mathematical communication skills, the students' mathematical ideas can be reflected, improved, discussed and developed. The communication process also helps the students to build understanding and belief of an idea" (p. 60). Based on the explanation above it can be seen that the mathematical communication is one of the important aspects that need to be developed in mathematics learning.

However, it is unfortunate that the process of mathematics teaching and learning in Indonesia still mostly oriented towards the mastery of basic skills, there is little emphasis on the application of mathematics in the context of daily life, communicating mathematically, and mathematical reasoning (Sadiq, 2007, p. 2). Based on information from the BERMUTU's program (Better Education through Reformed Management and Universal Teacher Upgrading) that issued by the Ministry of National Education also mentioned that Indonesia's ranking in the Trends in International Mathematics and Science Study (TIMSS) and the Programme for Internationale Student Assessment (PISA) is still far from the expectations. Indonesia's performance on the TIMSS 2007 was ranked 36th out of 49 countries, while based on the results of PISA in 2009, Indonesia was ranked only 61th out of 65 participants (Kemdiknas, 2011, p. 1).

The result of TIMSS and PISA that are lower is certainly due to many factors. One contributing factor as listed in the BERMUTU's program (Kemdiknas, 2011, p. 1-2), among others, is due to Indonesian students in general are less trained in solving problems with the characteristics of such matters in the TIMSS and PISA. This thing at least can be seen from the examples of learning outcomes assessment instruments designed by mathematics teachers of secondary school in Indonesia in the Development Model of Syllabus issued by BSNP in 2007. The syllabus commonly presents the learning outcomes assessment instrument which is substantially less associated with the context of the students' real life and less to facilitate students in revealing the process of thinking and arguing. Whereas the characteristics of matter TIMSS focuses on three domains, namely knowledge, application and reasoning, while focusing on PISA is literacy, that emphasize on skills and students' competencies who obtained from the school and can be used in in various situations of daily life.

Seeing these problems, we need a method of learning that allows students to be active, more freely to express their opinions, help each other, and cooperate with peers in solving problems to acquire the new knowledge. This is consistent with the statement of NCTM (2000, p. 61) that "to support classroom discourse effectively, teachers must build a community in which students will feel free to express their ideas." The conditions that favorable for the emergence of such matters is learning in a small-groups which called cooperative learning and make mathematics closer to students' daily life. One of the learning methods in accordance with those characteristics are contextual teaching and learning in cooperative setting. One of the advantages of cooperative learning are students can deepen their understanding as they discuss and exchange ideas with team members. Johnson (2011) revealed that "the cooperation can eliminate mental barriers due to limited experience and the narrow perspective. By working together to achieve a common goal, the students can also develop their mathematical communication skills because the students are required to explain their ideas, either orally or writing" (p. 164-165).

Furthermore, as it has been known that cooperative learning has many types. One type of structured cooperative learning model that supposedly can provide opportunities for students to develop mathematical communication skills is talking chips model. Lie (2008, p. 63) explains that talking chips model can be applied to all subjects included mathematics. In talking chips activities, each member of the group gets a chance to contribute and listen to other group member views and ideas.

According to (Kagan and Kagan, 2009, p. 6:11) "talking chips was developed to solve the problem of one or two students dominating a team discussion." Thus, the advantage of this technique is to overcome barriers of equal opportunities to contribute to the discussions that often happen in a group discussion. The learning activities like these can certainly have a positive impact not only on student learning outcomes but also open up opportunities for students to develop mathematical communication skills. Therefore, the researcher had collaborated the contextual learning method with talking chips type cooperative setting. This is accordance with the National Education Minister Regulation Number 22 (2006) which states that at every opportunity, the mathematics learning should begin with contextual problem. By filing a contextual problem, the learners gradually guided to master mathematical concepts." This is known as Contextual Teaching and Learning (CTL).

Berns and Erickson (2001, p. 2) define Contextual Teaching and Learning (CTL) as a learning process that aims to help students to understand the subject matter by linking the principal subject matter to its application in real-world situations and motivate students to connect knowledge with its application in their lives as family members, citizens, and workers, as well as engage in the hard work that requires learning. Then, for a deeper understanding of the concept of contextual learning, Center for Occupational Research and Development (CORD, 2012) describes CTL into five basic concepts of learning abbreviated REACT, namely: (1) Relating, forms of learning in the context of life or a real experience; (2) experiencing, learning in the context of exploration, discovery and invention; (3) applying, learn to apply the learning outcomes in a variety of real-life situations; (4) cooperating, learning by sharing information and experiences, and also communicate with other students; and (5) transferring, learning activities in the form of utilizing the knowledge and experience on new situations and contexts to gain knowledge and new learning experiences.

With the concept of CTL as described above, learning outcomes become more meaningful for students. The learning process takes place naturally in the form of students' activities work and experiences, not a transfer of knowledge from teacher to student. Contextual learning is a teaching that was developed with the aim of learning to walk more productive and meaningful. Furthermore, the observation and preliminary observation that researcher did in SMP Negeri 3 Sleman indicate that there were problems of mathematical communication skills at grade eighth students. The students mathematical communication problems demonstrated by the inability of students when asked to reveal the reasons in answering questions from the teacher. Additionally, when there was a problem that presented in a story form, the students got difficulties to create a mathematical model of the problems and also what they had written less structured. Furthermore, based on the observation obtained the information that the study of mathematics in grade eight of SMP Negeri 3 Sleman has not indicated the implementation of CTL approach in talking chips cooperative setting. The learning method that teachers did in teaching directly and question-and-answer method that both dominated by the teacher's role in presenting the material as well as the discussion of a practical exercise. It was less give opportunity for the students especially to develop their mathematical communication skills. Therefore, the researcher conducted this research on the effect of CTL approach with talking chips cooperative setting on mathematical communication skills of students in SMP Negeri 3 Sleman.

II. METHODOLOGY OF THE RESEARCH

A. Type and Design of Research

This study was a quasi-experimental research. It was used pretest-posttest with nonequivalent groups design. The researcher used two groups of participants, namely the experimental group and control group. The experimental group was given treatment in the form of CTL approach with talking chips cooperative setting and in control group used conventional approach. Furthermore, both groups were given tests of mathematical communication skills.

B. Time and Place of Research

The research conducted at SMP Negeri 3 Sleman located at Magelang street Km. 10, Ngancar, Tridadi, Sleman, Yogyakarta. The data was conducted in March-May, 2013.

C. Population and Sample of Research

The population in this research was all the students of grade eight at SMP Negeri 3 Sleman. The grade eight students consisted of six classes, they were class VIII A to VIII F which totaled 192 students. The sample in this research was determined by using cluster random sampling because the researcher could not directly select a random sample of individuals. In this research the class VIII A randomly chosen as the experimental group, whereas class VIII B as the control group.

D. Variable of Research

The variables in this research included independent variable in the form of learning approach with two levels that used CTL approach with talking chips cooperative setting and conventional learning approaches, as well as the dependent variable was the mathematical communication skills.

E. Techniques and Instrument of Data Collection

The data in this research gained directly by the researcher by providing treatment in the experimental group. The data collected by the test to measure the ability of mathematical communication. Meanwhile, the instrument used in this research was mathematical communication test in form of essay.

F. Validity and Reliability of Instruments

The proof of the validity of the instrument in this research using content validity that gained from the experts. And for estimating the reliability of the instruments used alternate-forms methods or equivalent methods because the instrument in this research consisted of two parallel types of tests (similar but not identical) namely pretest and posttest. The results of the instrument reliability coefficient was 0,58.

G. Data Analysis Technique

To determine whether there is any effect of CTL approach with talking chips cooperative setting compared and conventional approaches to mathematical communication skills used Independent Sample T-test. The hypothesis tested was:

$H_0 : \mu_1 \leq \mu_2$ (CTL approach with talking chips setting was not better than conventional approach in terms of mathematical communication skills)

$H_1 : \mu_1 > \mu_2$ (CTL approach with talking chips setting was better than conventional approach in terms of mathematical communication skills)

To perform a statistical test with independent sample T-test can be performed using the SPSS program. Criteria for the decision is to reject H_0 if the sig value< $\alpha = 0{,}05$. But before doing t test, the assumption of normality and homogeneity must be fulfilled. Normality test was done by Kolmogorov-Smirnov test while the homogeneity test can be seen from Lavene's test. Both were performed using the SPSS program. Particularly, if the assumption can not be fulfilled then the data can be analyzed using non-parametric method. Non parametric method will be used when the data has an unknown distribution, is non-normal, or has a so small sample size that the central limit theorem can not be applied to assume the distribution. Hence, this method is sometimes referred to as distribution-free method. U Mann-Whitney test is a kind of non-parametric test that can be used to see if there is difference between two groups. Thus, U Mann-Whitney test will be used by researcher when the asumption of parametric test can not be fulfilled.

III. **RESULTS AND DESCRIPTION OF RESEARCH**

A. Result of Research

Based on the research conducted, the data obtained were presented in Table 1.

Table 1. Mathematical Communication Test Result

Description	**Experiment group**		**Control group**	
	Pre-test	***Post-test***	***Pre-test***	***Post-test***
Mean	49,33	72,63	48,13	55,04
Varians	12,85	15,81	10,24	14,89
The highest score	68,75	96,88	73,44	79,69
The lowest score	18,75	35,94	34,38	17,19
Ideal maximum score	100	100	100	100
Ideal minimum score	0	0	0	0

Based on Table 1, it appears that the final condition after treatment, there was an increasing score of mathematical communication skills both in the experimental group and the control group with a range of different upgrade. In the experimental group the average score increased in 23,3 point from the initial score of 49,33 into 72,63. While the control group improved score was 6,91 that occurred from baseline 48,13 into 55,04. Furthermore the result of data analysis was presented as follow.

1. Normality Test
   The results of normality test with Kolmogorov-Smirnov test using SPSS program on pretest data for the experimental and control groups respectively obtained sig value 0,147 and 0,001. Because 0,147> 0,05, while 0,001 <0,005, it can be concluded that the experimental group of normality assumption fulfilled while in the control group unfulfilled. Besides, normality test results to the posttest data obtained sig value for the experimental and control groups respectively 0,2 and 0,082. Thus, the assumptions of normality were fulfilled for both groups.
2. Homogeneity Test
   Based on the results of Levene's test with SPSS program for data pretest obtained sig value of 0,2. Because 0,2>0,05, it can be concluded that both are homogeneous group. Furthermore, to the posttest data obtained sig value of Levene's test 0,777>0,05 so the assumption of homogeneity are also met.
3. *U Mann-Whitney* Test (non-parametric method)
   Because the pretest data normality assumption was unfulfilled then non-parametric method was used to analyze the pretest data. U Mann-Whitney test was used to see if there were any differences in mathematical communication pre-ability between the two groups. The test result used SPSS program obtained sig value 0,259>0,05. Thus, it can be concluded that there were no differences in pre-ability mathematical communication between the two groups.
4. *Independent Sample T-test*
   The results of independent sample t-test on the posttest data obtained sig value 0,000 where 0,000<0,05. This result was significance. Furthermore, the average mathematical communication test value of the experimental group that was 72,63 more than the control group 55,04. Thus, it can be concluded that the CTL approach with talking chips cooperative setting was better than the conventional approach in terms of students' mathematical communication skills.

B. Description

Based on the hypothesis test was known that students who received mathematics learning using CTL approach with talking chips setting had an average of mathematical communication ability more than students who received conventional learning approach. While it can be said that the CTL approach with talking chips setting had effect towards the junior high schools students' mathematical communication. This result is most likely due to the learning steps were carried out, especially at the talking chips part that strongly support students to develop their mathematical communication skills. It is accordance with (de Walle, 2008, p. 4-5) that discussion between students will be able to explore mathematical ideas from different view point, so that students can add their mathematics understanding. By working together to achieve a common goal, the students can develop mathematical communication skills because they are required to explain their ideas, either orally or writing. Talking chips technique that used in the discussion also makes students more responsible in group, because for each member of the group is required to have the same capacity to participate in the discussion. In accordance with Kagan (2009) the talking chips model have a function as a regulator of the communication and fluency builders because each student is responsible for participating. This is also supported by the CTL approach which has the principle of making the material closer to the students' daily life. This principle can make meaningfulness learning experience for students so they can easily understand the material content.

From the description above, the theories that have been studied by researcher was suitable with the result of research. The CTL approach with talking chips cooperative setting is better than the conventional approach in terms of students' mathematical communication skills, especially in grade eight students of SMP Negeri 3 Sleman.

IV. CONCLUSION AND SUGGESTION

A. Conclusion

Based on the results of data analysis and description, it can be concluded that there was an effect of CTL approach with talking chips cooperative setting on mathematical communication skills of grade eight students of SMP Negeri 3 Sleman. CTL approach with talking chips cooperative setting is better than conventional learning approaches in terms of students' mathematical communication skills.

B. Suggestion

In accordance with the finding and discussion, there are some suggestions that can be conveyed as follows.

1. The CTL approach with talking chips cooperative setting is proven in theory and supported by empirical research data can be selected as an alternative learning model to support students' mathematical communication skills.
2. For similar research, it can be suggested to make three groups design of research consisting of CTL with talking chips setting group, CTL only group and control group in order to know clearly what is more influence on students' mathematical communication skills.
3. For further research it can be suggested for using CTL approach that varied with the other type of cooperative learning model so the discussion groups can be more interesting and not boring. Last but not least, the mathematical communication skills have to be more emphasis on students' ability to create a mathematical model.

Developing A Mathematics Instructional Model Based On Child Friendly, Innovative , Creative and Realistics (CFICR) At Junior High School

Nining Setyaningsih[1)], Sri Rejeki[2)]
[1] Department of Mathematics Education, FKIP,UMS
[2] Department of Mathematics Education, FKIP,UMS
nining.setyaningsih@ums.ac.id

Abstract. The aim of this study is to develop the mathematics instructional model based on CFICR (Child Friendly, Innovative, Creative and Realistics) at Junior High School. This study is a development research, conducted in the form of development model proposed by Tjeerd Plomp as in [6]. It consists of four development phases: (1) the preliminary investigation phase conducted to get information about mathematics instructional model theories, learning theories and the analysis of the mathematics in Junior High School, (2) the design phase conducted to design the instructional model based on CFICR, (3) the realization phase conducted to develop mathematics instructional model by following the design phase and (4) the revision, evaluation and test phase of the mathematics instructional model prototype being developed and was validated by an expert in learning mathematics and try out. This research was conducted at the Junior High School Muhammadiyah Program Khusus Surakarta. These result of this study shows that: (1) the learning management based on CFICR by teacher was in " very good" category with score 3,50 , (2) the prototype model had improved students' activities were in "very good" category and (3) the students' responses toward the mathematics instructional model was included in "positive" category. Besides that, it was obtained the instructional mathematics model based on CFICR with the following syntaxes: (1) explaining the learning objectives and motivating students, (2) giving the contextual problems that are familiar with students, (3) processing mathematics' abstraction (mathematics vertically), (4) formulating the solving strategies, (5) communicating the result of discussion and (6) giving the inferences of mathematics material.

Keywords: *child friendly, creative , innovative and realistic*

I. INTRODUCTION

Education is a conscious effort of man to guide humans in order to develop the personality and ability in accordance with the values that prevail in society. Education in school can not be removed from the process of learning and interaction between teachers and students. Reference [2] giving definition of learning is a permanent change in response highly potentiality which accurs as a result of reinforced practice. From this definition, it means that learning can produce behavior change relatively permanent students and teachers as doer change. Thus, learning is the assistance given by teachers in order can occur the process the acquisition of science and knowledge, mastery of skills and behaviour, as well as the formation of attitudes on students. In other words, learning is a process to help students to learn well. Thus, the teacher is a spearhead for feeding children contributed. The magnitude of the responsibility, then the Government gives awards for teachers by placing teachers as professionals who poured in to law teachers and professors in 2005. Teachers as professionals must have the four competencies that are teaching competence, professional competence, social competence and personality competence.

However, as in [10] states based on the results of a survey conducted by the Directorate General PMPTK informed that the most of the teachers have a low competence and the most of them have not been trained on the pedagogics. This condition is in line with research conducted Herry W as in [4] which informs the low ability of teachers in the assessment of learning outcomes and learning management. This means there are still many teachers that have low competence in teaching and learning. Because of that , they still dominate in teaching a class, do not involve students actively in the learning. They still adhere to pragmatism is everything, teachers consider the students as an object not as the subject. So with this condition, it resulted in a low level of activity and creativity of students in learning.

On the other hand, the results of research conducted by Slamet Hw, Nining as in [9] said that students need to have (1) the ability related to mathematics that can be used in solving mathematical problems, another lesson, or problems related to real life; (2) the ability to use mathematics as a tool of communication; and (3) the ability to use mathematics as a way of reasoning that can be used in any circumstances, such as critical thinking, logical thinking and systematic thinking. Reference [5] and [8] also conclude in their research that in learning mathematics liveliness, creativity and communication of mathematics students are urgently needed to improve the understanding of mathematical concepts. This will not be easily filled by students, if it is not supported the ability of teachers in teaching as well as learning resources . The learning resource limitations is one of the obstacles during the process of learning. In addition to these problems and supported teachers' ability in learning conditions are also very poor, it is necessary to find solutions to solve those problems.

From the above explanation , then it needs to be developed the mathematics instructional model based on Child Friendly, Innovative , Creative and Realistics. This research needs to be done in order to support the implementation of the curriculum of 2013 and also to increase students' activity and to improve the creativity of teachers in the teaching and learning of mathematics.

Child friendly learning refers to the the condition of the school/class that is a friendly place for students to learn. Friendly defined as a condition that is safe, joyful, and free. Safe refers to a condition that is free of violence and arbitrariness. Joyful is a condition of class that make students learn with pleasure. Free refers to the freedom of students to speak their opinion. According to Ricardo, Molly as in [7] said that the inclusion of mathematical activities in the museum, science center and other informal inveroments has the potential to complement formal learning in school mathematics classrooms, promote possitive attitudes to ward of the mathematics. This means the learning process does not have to occur in the classroom, but it can be done outside the classroom even outside of school. Thus, with this condition will be created in the process of learning, in which students free expression and gives an opinion, so that students will participate actively in teaching and learning. One type of approach in learning mathematics is a realistic approach. According to refrence [3] stated that learning mathematics with the realistic approach is an approach in which mathematics is seen as something human activities.

II. Material and Method

Child friendly learning refers to the the condition of the school/class that is a friendly place for students to learn. Friendly defined as a condition that is safe, joyful, and free. Safe refers to a condition that is free of violence and arbitrariness. Joyful is a condition of class that make students learn with pleasure. Free refers to the freedom of students to speak their opinion. According to reference [7] said that the inclusion of mathematical activities in the museum, science center and other informal inveroments has the potential to complement formal learning in school mathematics classrooms, promote possitive attitudes to ward of the mathematics. This means the learning process does not have to occur in the classroom, but it can be done outside the classroom even outside of school. Thus, with this condition will be created in the process of learning, in which students free expression and give an opinion, so that students will participate actively in teaching and learning.

One type of approach in learning mathematics is a realistic approach. According to reference [3] stated that learning mathematics with the realistic approach is an approach in which mathematics is seen as something human activities. The principal activities done in learning mathematics with the realistic approach are (1) using real-life contexts as a starting point for learning; (2) connecting to among strands, to other disciplines, and to meaningful problems in the real world; (3) using models as a bridge between abstract and real, that help students learn mathematics at different levels of abstractions; (4)

using student's own production or strategy as a result of their doing mathematics; and (5) interacting as an essential for learning mathematics between teacher and students, students and students. By using a realistic approach, students doing troubleshooting informally (using its own language), but after some time the familiar with the processes of solving similar, they will use more formal language and end the process students will find an algorithm.

This research includes the type of research development that the research oriented on the development of a product development process are described carefully and products obtained have been evaluated. The product of this research is a mathematics instructional model based on CFICR. The development model of learning mathematics based on CFICR is the main activity in this research. The development model used to develop this learning model refers to the model of development of public education from Tjeerd, Plomp as in [6]. It consists of four development phases: (1) the preliminary investigation phase conducted to get information about mathematics instructional model theories, learning theories and the analysis of the mathematics at Junior High School, (2) the design phase conducted to design the instructional model based on CFICR, (3) the realization phase conducted to develop mathematics instructional model by following the design phase and (4) the revision, evaluation and test phase of the mathematics instructional model prototype being developed and was validated by an expert in learning mathematics and try out.

This research was conducted at the Junior High School Muhammadiyah Program Khusus Surakarta grade VII. The source of the data for the validity of the model is an expers competent in the fields of the development of the model and the source of the data for the practicality of the model are an expert in the field of development, researchers and teachers who carry out learning . The source of the data for the effectiveness of the model are students.

The data analysis techniques used in this research to know the validity of the model are (a) doing the recapitulation statement validator and (b) determining the validity of the results of the compatibility with the criteria already defined. For knowing the practicality of the model are (a) doing the recapitulation statement validator and (b) determining the practicality with compatibility results with criteria that are already determined. And to know the effectiveness of the model at the end of the cycle will be given the question form of students' response about implementation models as well as the activity of students in learning.

III. RESULT AND DISCUSSION

The results of the development of mathematics instructional model based on **CFICR** of every phase are as follows:

a. The results of the preliminary investigation phase, i.e. the concept and theory of the curriculum of 2013, child friendly school (child-friendly), creative learning, innovative and realistic learning model and analysis of the material fractions grade VII about comparing fractions and operations of fractions.

b. The results of the design phase are : (1) design of mathematics instructional based on CFICR with the phases of the syntaxes are as follows (a) explaining the learning objectives and motivating students, (b) giving the contextual problems that are familiar with students, (c) processing mathematics' abstraction (mathematics vertically), (d) formulating the solving strategies, (e) communicating the result of discussion and (f) giving the inferences of mathematics material; (2) the design of the learning environment or social system, i.e. the situation or atmosphere and norms that apply in the model of learning that will be developed , such as the role of the teacher and the student to do activities for learning to take place, (3) the principle of reaction, that is related to how teachers in the notice and treat students in the learning process, (4) supporting model based on CFICR, i.e, materials/devices/media tools and learning that supports the implementation of the model and (5) the evaluation is to evaluate achievement of learning objectives pertaining to the mastery of the material with a learning model based on CFICR.

c. The results of the phase of realization is a model of learning mathematics based on CFICR prototype I .

d. The results of the test phase, evaluation, and revision are twofold, namely : (a) the results of the validation and (b) the results of the field cycles. The results of the validation showed that learning model based on CFICR that developed including the requirement is valid, because it meets the validity of the constructs and content. From the results of cycles conducted in field indicates that:

1) At the first cycle, as seen from the practicability of learning models showed the ability of teachers in the management of learning including categories is not good. This indicated the implementation of learning syntax CFICR not yet implemented properly, with a score of 2.75. While judging from the model effectiveness is measured from the activity and the response of students showed that 65% of students include the requirement of active in the learning process and responded positively towards the implementation of the learning model CFICR. So it can be said that the model of learning mathematics based on CFICR developed empirically is not practical and effective.
2) In the second cycle, as seen from the practicability of learning models showed the ability of teachers in the management of learning including categories less well. This indicated the implementation of 2 stages in learning syntax CFICR have not been executed and the score obtained in the learning management 3.0. So it can be said that the model of learning mathematics based on CFICR developed empirically is not yet practical. While judging from the model effectiveness is measured from the activity and the response of students showed that 75% of students include the requirement of active in the learning process and responded positively towards the implementation of the learning model based on CFICR. So it can be said that the learning model has not been effective.
3) On the third cycle , as seen from the practicability of learning models showed the ability of teachers in the management of learning including categories either. This indicated the implementation of all stages of the learning CFICR syntax was implemented by a score of 3.50. While judging from the model effectiveness is measured from the activity and response indicates that 90 % of students include the requirement of active in the learning process and responded positively towards the implementation of the learning model based on CFICR. So it can be said that the model of learning mathematics based on CFICR developed empirically is already practical and effective.

Thus, after the last cycle then it obtained a prototype of the final mathematics instructional model based on CFICR that is valid, practicality and effective. Implementation of this model will be implemented in the second year, i.e. the year 2016. From the results of those cycles indicate that the model of learning mathematics based on CFICR can increase the ability of teachers in the management of teaching and students' activities in learning as well as responded positively towards the implementation of this model.

This condition as a result of the implementation of the learning that begins at the initial phase of mathematics instructional model based on CFICR that is the teacher giving the contextual problems that are familiar with students. The teacher provides contextual problems. In this phase the teacher have to creativity and innovation in finding a contextual problem, so as to stimulate the creativity of the students. Students identify the problems individually. Based on their identification, students discuss the problems in their group in order to know the similarities and the differences of students' understanding of the problems. Afterwards, they have the same understanding regarding the problems. Students identify the problems individually. Based on their identification, students discuss the problems in their group in order to know the similarities and the differences of students' understanding of the problems. Afterwards, they should have the same understanding regarding the problems. The teacher encourages students to express their ideas. Each student in every group presents their ideas about the problems given and makes relations to other concepts or to realistic situations. Students in their group formulate the mathematics model based on their ideas. The model can be a bridge to connect the realistic problems and the abstract forms. This research in line with refernce [1] and [11] statement, that during the course of the study, an effort was continually made to encourage students to go trough the RME approach of simplifying the contextual problem by first represeting it in their own symbols and/or words and then futher solving and interpreting it from there.

IV. CONCLUSION

The conclusions obtained in this study are:

a. A theory of development which is used to develop a model of learning mathematics based on CFICR is modifying the development theory has been said by Tjeerd, Plomp as in [6] which contains the phases (1) the preliminary investigation phase (2) the design phase , (3) the realization phase and (4) the revision, evaluation and test phase.
b. The learning management based on CFICR by teacher was in " very good" category with score 3,50 ,
c. The prototype model had improved students' activities were in "very good" category and the students' responses toward the mathematics instructional model was included in "positive" category.
d. The instructional mathematics model based on CFICR with the following syntaxes: (1) explaining the learning objectives and motivating students, (2) giving the contextual problems that are familiar with students, (3) processing mathematics' abstraction (mathematics vertically), (4) formulating the solving strategies, (5) communicating the result of discussion and (6) giving the inferences of mathematics material.

Abstract— This article set out scaffolding as one of proper tools for heterogenous groups in class. It is particularly useful supporting low-achieving students (LAS). Low achievers have lack of not only minim abality understanding mathematics matery, but also lack of motivation to involve in practices. According to socio-constructivism by Vygotsky, scaffolding is needed to help students achieving zone of proximal development (ZPD). Additionally, *scaffolding* is one of the strategies used by children and novice for solving problem, finishing the tasks, or reaching a goal of learning process beyond their capability. It is northworthy for teachers developing either micro-scaffolding or macro-scaffolding for exploring potential of LAS. Scaffolding can be trigger for students having mathematics problems, especially in inclusive class. Thus, this article exhibit further review how scaffolding is crucial thing to increase LAS understanding in mathematics class.

Keywords: *scaffolding, low-achieving students (LAS), mathematics learning*

I. INTRODUCTION

The attention toward mathematics education becomes so very important in the world. This is evident from some of the developments that are so significant on the planning implementation of learning mathematics happening in the world. In fact, in a innovation study of mathematics will always progressing continuously. The challenge in the development of mathematics education itself is how to develop a meaningful mathematics learning and can provide a deep understanding of the students from each of the materials given during learning. It is inevitable that in any implementation of learning mathematics, many things that are a challenge someone as a teacher. It is happened because the ability of students differ from each other. Anyone has high math ability and others have low math ability. Given the diversity of capabilities that exist in students, then ineducation, especially in mathematics, low-achieving students (LAS),need to get more attention. In this case, poor understanding of the mathematics learning material will result in students having low achievement.

In this condition, there are things that need to be focused on that issue which is focusing on students who have low achievement. The strategy and understanding toward the characteristics of low-achieving students becomes crucial to be considered and acted in order to be able to understand the learning material of mathematics to be meaningful. The ways or strategies that can be done is by learning using strategies scaffolding. Bakker, Smit, and Wegerif (2015) revealed that the scaffolding has thepotential concept form integrated with applications in mathematics education.It indicates that learning through the scaffolding isessential in exploring the differences that exist on the mathematical conceptsthat are interrelated.

In the other side, Makar, Bakker, and Ben-Zvi (2015) revealed that the scaffolding as aassistance temporary and customized by a teacher or a student who has more knowledge to support students with low math ability to solve a mathematics problem. From the above explanation, the authors intend to provide an overview study about how the scaffolding strategies can help the students to understand learning material of mathematics.

II. LITERATURE REVIEW

A. Characteristic of Low-Achieving Students (LAS)

According to Broza and Kolikant (2015), there is no single definition of low-achieving students (LAS). Nonetheless, based on a recent meta-analysis (Baker et al. 2002), they categorized LAS based on teacher report on standarization of students' performance or informal tests. In this article, the term LAS focuses on mathematics cognitive deficiencies and on behavioral manifestationsof their failures. They are often pointed having mathematical learning difficulties or mathematical disabilities. Craik (2002) refers to this difficulty as *'fragilememory'*, a product of superficial data processing. There are empirical studies that characterise low achievers' mathematical competence and describe the specific difficulties low achievers experience in mathematics. These students often have difficulties in specific arithmetic areas such as conceptual understanding, such as the decimal place value system and problem solving (Mazzocco et al. 2008), and procedural competencies, such as counting or memorizing number facts LAS find it difficult to retrievebasicmathematics knowledgefrom their memory (Gray,PittaandTall cited by Broza and Kolikant, 2015).

Johnson and Schmidt (2006) described many students in this class lack not only accuracy with basic mathematical operations but they have a deep-rooted belief that they will never be very good at solving math problems. One of the goals for mathematics learning class is for students not only to develop their mathematical concept but also confidence in their own ability by helping them to become better problem solvers. They also lack meta-cognitive skills (Goldman1989),and are sensitive to the learning contexts. They have lack of basic of mathematics, thus find it much harder than others to solve simple and complex addition and subtraction problems. These difficulties may lead them to use less sophisticated strategies and commit more errors. Experiencing repeated failures and difficulties in keeping up with the class might in turn decrease the irmotivation and sense of internal responsibility and make them more passive learners. It might also lead themtoact impulsively,relying on the others judgment to them.

Afterward, there is a important question of how to increase the effectiveness of teaching and learning processes presents an important challenge to LAS; what type of support can be provided by the teacher to facilitate the student'construction of meaningful knowledge in mathematics class? Teaching the complex topic of mathematics to low achieving students (LAS)poses a special challenge, due to LAS' weaknesses such as memory deficiencies, inadequate use of strategies for solving mathematics tasks, deficiencies in generalization andtransfer of learned knowledge to new and unknown tasks,social problems, and mathematics anxiety (Haylock cited by Broza and Kolikant, 2015).

Despite LAS are having their difficulties, LAS can as well increase their mathematical conceptual of understanding. Karsenty, Arcavi andHadas (2007) and Chazan (2000) find the fact that LAS are able to display mathematical reasoning orally when placed in intimate and supportive learning circumtances.Peltenburg (2012) revelas that in Mathematics ICT usage, LAS show successfull performance in solving subtraction problems by using an indirect addition strategy spontaneously, rather than the conventional direct subtraction strategy. Similar to these studies, our approachhere is based on the belief that LAS are capable of meaningful learning in mathematics, and on the desire to capitalize on strengths and successes, rather than to focus solelyon weaknesses. LAS tend to contextualize mathematics and their concept of mathematics is associated with "doing"(Gray et al. 2000).

To enhance LAS performance in mathematics learning, They need teachers' supported in term scaffolding to trigger and explore LAS' thingking and behaviour effectivelly. It is a crucial thing for students because Some research suggests that a lack of mathematics competency such as in basic arithmetic operations can have a negative impact on success in math class (Gersten & Chard, 1999), it will affect to their confidence and motivation in the class.

B. Scaffolding

The concept of scaffolding is originated within Vygotsky's theory in learning approach. Cf Gibbons (Prediger & Pöhler, 2015) The main idea of scafsky's classical construct that using as tools to help students through zone of proximal development (ZPD). Wood,Bruner,and Ross (1976)Is first described *scaffolding* as "the process [which] enables a child or novice to solve a problem, carry out a task or achieve a goal which would be beyond his unassisted efforts"(p. 89).Broza and Kolikant (2015) defined that there are six elements of scaffolding that involve cognitive, meta-cognitive, behavioral, emotional and motivational aspects (p.1094). In the class, scaffolding designed students' learning performances, keeping the novice to finish learning objectives. Furthermore, the facilitator designing the learning behaviour and makes decisions about which stimulating tasks to use, whether and when to interveneand support,and howmuch and what type of help is necessary(Wood, 2001;Prediger & Pöhler, 2015).

Practically, there is no specific definition to describe what the scaffolding is. Nevertheless, Van de Pol, Volman and Beishuizen (2010) identify the notion of scaffolding published over the years commonly refers to support given by teachers to students or students through interaction (Broza.,et.al 2015) catching cognitive proximal level of students. Broza.,et.al 2015 identify three elemens of scaffolding regularly appeared during teaching and learning (see figure 1); (1) The*contingency*, it is refers to responsiveteaching,orthecalibrated support (Broza.,et.al 2015) students' interaction along the class, providing learningsupport which is contingent on learners'needs when errors occur is considered effective for developinglearners'understanding (Wischgoll, Pauli, &Kurt Reusser, 2015);(2)*fading*, the circumtances which is "gradually removing teacher scaffoldsas the student gainsunderstandingand no longer require the teacher'ssupport" (Broza.,et.al 2015, p. 1094); (3) A gradual *transferof responsibility* to the student. It is needed to be accompanied in fading elements.The teacher offers a lot of support at the beginning,and successively fades out this support in order to transfer responsibility to students.

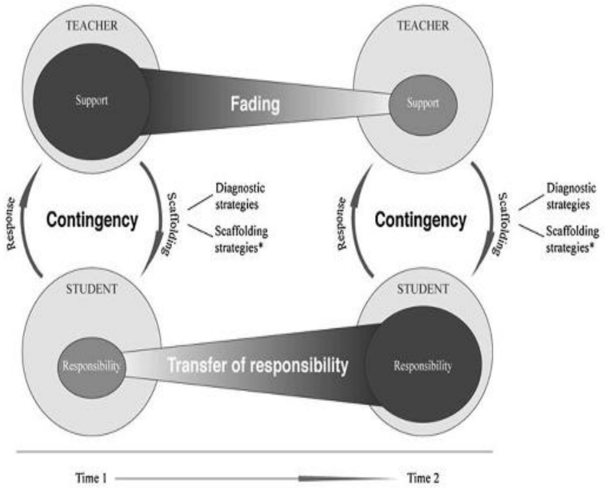

Figure 1. Model of key aspects of scaffolding
Van de Pol (S. Prediger, B. Pöhler, 2015, p. 1180)

According to Hammonds and Gibbon (Plister, et al. 2015), scaffolding can be divided as two notion macro-scaffolding and micro-scaffolding, those distingushed at which those are implemented.Macro-scaffolding has more massive area than micro-scaffolding. Gibbons (2002) and Smit (2013) cited by (Prediger & Pöhler, 2015), Macro-scaffolding as an empirical reconstruction which consists of students' prior experience, the learning goals for sequencing intermediate learning goals and support means, and instructional tasks along the intended learning trajectory. So that, macro-scaffolding includes teachers' preparation of planning, goal setting, classroom organisation, and the selection and sequencing of tasks, and contingent interaction in response to the teaching and learning opportunities.

Meanwhile, Micro-scaffolding is an important *local* phenomenon on a micro-scale of teacher-student-interactions (Prediger and Pöhler, 2015). It is fuzzy specific learning trajectory which is students' responsiveness to construct their concepts themselves, the idea supporting students to move forward in zone of proximal development (ZPD). Prediger & Pöhler (2015) highlight micro-scaffolding includes in macro-scaffolding, the role of micro-scaffolding in the interplay of conceptual and lexical learning.

According to Plister, et al (2015, p. 1080), The best scaffolding usage for students should offer activity consists of (1) *Feeding back*: Inside of scaffoding teachers should be providing information regarding the student's performance; (2) *Giving hints*: providing clues or suggestions will guided them to find the concepts. (3) *Instruction*: The scaffolding demonstrate what to do or how something must be done and why; (4) *Explaining*: providing more detailed information or clarification; (5) *Modelling*: offering behaviour for imitation and (6) *Questioning*: questions that require an active linguistic and cognitive answer. The study reported in this article empirically investigates how micro- and macro-scaffolding *depend on each other* i.e scaffolding implementation depends on the teacher itself.

C. Scaffodling for Low-achieving students (LAS)

Plister, et al (2015, p. 1081) categorizes that they are called "facets", which is aspects of scaffolding to create high quality mathematics learning for low-students. In addition, those facets are used to see how success implementation of scaffolding in inclusive class. They consits of the five following facets are listed and described.

(1)*Cognitive activation*: Krammer (Plister, et al, 2015, p. 1081) argue that cognitive activation is crucial aspect to construct students' conceptual understanding, others, it provides students' (meta) cognitive activation as well. Furthermore, cognitive activation also includes fading and transfer responsibility. To build cognitive activation in learning, students are guided to active participate in whole activity. The more active participation of students in the class, the more the responsibility during their performance will be gotten to them. Then, the last and essential part in this facet is the teachers' should invite students together to do summarize of what has been done or said during the activity (Williamsand Baxter1996),and theemphasis ison asking questions,rather than givingdirections (Lepper, Drake& Johnson.1997);

(2) *Stimulating discourse*: One of the way to achive cognitive activation is discourse orientation for learning, it is about interaction among teachers and students and between students one another (Krammer 2009). They have a time to communicate mathematical concept during the lesson. Williams and Baxter (Plister, et al, 2015) present scaffolding as a coreelement of discourse-orientated learning "…to describe actions taken by a teacher that support the creation of mathematicalknowledgethrough discourse among students"(p.1081). In addition, cooperative learning model can be choosen as the way to build discourse-oriented learning.

(3) *Handling errors productively*: A teacher should have a way to tackle students' errors and misconseption effectively. In the early, most of learning process utilize discourse usage, we often find students getting a misconception and an error. Based on a study by Lepper et al. (1997), the best tutors have the proper way to respond students' errors differently than other colleagues.Teachers are guided able to appear students' awareness about their errors and misconception by posing leading questions or offering hints to prompt students to identify and correct the errors by themselves (Plister, et al, 2015, p. 1081).

(4)Target orientation: In the beginning, teachers has to provides approriate tasks and mathematics problem which is used as guide for students' performance. According to Williamsand Baxter, It consists of utilize compatible questions, instructions, and explanations to draw students' attention that use to construct mathematical concept by themselves.selected instructional examples,
and thus to key concepts or "mathematical ideas" (Plister, et al, 2015).

(5)Using Manipulatives: In mathematics instruction, how to construct mathematics conceptual understanding needs contextual problem, thus theway problems presented is especially important. Teachers should make consideration how to present a problem to the students, includes finding

compatible way to each problems being given examples in term of manipulatives andrepresentations (Lepperetal.1997).Every students in mathematics most likely easy to understanding the matery presented with active representation and contextual problem, particularly for LAS (cf. Sect.Plister, et al, 2015).

The "facets" above can be consideration for the teachers that design techniques of scaffoding to enhance LAS in mathematics learning. Although, the idea of scaffolding was originally developed relying on the teacher itself, for the use in one-to-one tutorial situations by the teachers; however, it is now also able to be applied to classroom situations (Smit et al. 2013).

III. Conclusion and Discussion

In mathematics class, the LAS have a lack of mathematics conceptual understanding and motivation. They show massive anxiety of mathematics based on their failure experience in mathematics class. Pfister et al studies about scaffolding usage (2015) found that scaffolding are usefull tools to increase LAS performance in the class. However, it needs professional preparation before scaffolding used. The five facets which hipothesized are able to enhance LAS performance- means are inluded all of facets, are not as easy as applied during the lesson. Teachers, even training teachers (i.e teachers have got the scaffolding training using five facets), going to find obstacle to provide it to LAS correctly.

Nevertheles, it is important to understand how to encourage classroom teachers to use scaffolding and how to train them to use the various techniques in scaffolding. Lepper et al. (1997) discuss some types of training (i.e.peer-tutoring programs and computer tutors). Because the role of scaffolding toward enhancing understanding of low-achieving students (LAS) in mathematics learning. Thus, On the basis of Lipowsky's (2004) results, we recapitulate that pre-service and in-service (i.e class teachers and special education teachers) training in scaffolding techniques would be an effective option.

Mathematics is not only about using numbers to fulfill the formulas or performing computations, but also a way of thinking. Based on NCTM, there are five standards in learning mathematics. Those are problem solving, reasoning and proof, communication, connection and representation. Mathematical reasoning is one of the ability that students must have after learning mathematics. Mathematical reasoning cannot be separated from learning mathematics. Mathematical reasoning have an important role in the proccess of understanding and applying mathematics. At the same time, mathematical reasoning also developed while we are learning mathematics. We often use deductive reasoning when we learn mathematics in school. Whereas, we also can use another kind of reasoning, inductive reasoning, to learn mathematics. One of components mentioned in inductive reasoning is analogical reasoning. Analogical reasoning is a process of thinking to obtain a conclusion or new knowledge by comparing analogical objects or their prior knowledge about something. Based on some research, inductive reasoning, especially analogical reasoning, can be used to develop students' ability in mathematical reasoning. As a teacher, we can desain a learning program which can fostering student's analogical reasoning ability. Because of the goals of learning mathematics is not only about matematics as the product of thinking, but also the process of learning and thinking, it is important for us to prepare and planned a good learning program. Focus on analogical reasoning, this paper is aimed to describe how mathematical reasoning can be developed through fostering student's analogical reasoning ability and how we can bring it in our mathematics learning program.

Keywords: *analogical reasoning, learning mathematics by analogical reasoning, mathematical reasoning*

I. INTRODUCTION

Mathematics is one of lessons thaught from elementary until secondary school. The aim of learning mathematics is to provide logical thinking, critical thinking, and creative abilty. Mathematics is not only about using numbers to fulfill the formulas and performing computations, but also a way of thinking. Based on NCTM[1], there are five standards in learning mathematics. Those are problem solving, reasoning and proof, communication, connection and representation. Reffered to this standards, mathematical reasoning is important things in learning mathematics. Reasoning is the proccess of thinking. Moreover, mathematical reasoning and mathematics are two things that cannot be separated. Mathematical reasoning is a fundamental ability which have an important role in the proccess of understanding and applying mathematics. At the same time, mathematical reasoning is also developed while we are learning mathematics.

Learning mathematics involve two aspects of reasoning. They are deductive and inductive reasoning. According to Fathima[2], inductive reasoning is generalization of the principles or conclusion of specific facts. One type of inductive reasoning is analogical reasoning. Several studies found a close relationship between student's analogical reasoning ability and student's mathematical reasoning ability. Alexander and Buehl[3] found evidence of relationship between them. Moreover, Goswami[4] stated that "experience in solving analogical problems and habit of thinking about the relationship between things that have similar properties can enhance one's mathematical ability". Alexander, White and Daugherty[4] suggested that the process of reasoning in mathematics has close correspondence with analogical reasoning process. They found that there is a strong relationship between analogical reasoning ability of someone with their mathematical reasoning ability. Viewed from that several studies, there is a close relationship between analogical reasoning ability with mathematical reasoning abilities. We can conclude that the role of analogical reasoning in the proccess of learning mathematics is very important because problems which involving analogical reasoning can be used to improve students mathematical reasoning abilities. Teachers can use learning process in the classroom to facilitate the development of student's mathematical reasoning ability throught analogical reasoning. This is accordance with the opinion of Mofidi[5] that one of the effective methods can be used by teachers to teach mathematics concepts is to use issues involving analogical reasoning. This paper will discuss how mathematical reasoning can be developed through fostering student's analogical reasoning ability and how we can bring it in our mathematics learning program.

II. EXPLANATION

A. Mathematical Reasoning

Mathematical reasoning is one of the student's ability that must be developed in learning mathematics. Steen[6] defined mathematical reasoning as "reasoning about and with the objects of mathematics". On the other hand, Russel[6] defined "mathematics reasoning is essentially about the development, justification and use of mathematical generalization". Based on NCTM[7], "Reasoning in mathematics is often understood to encompass formal reasoning, or proof, in which conclusions are logically deduced from assumptions and definitions. However, mathematical reasoning can take many forms, ranging from informal explanation and justification to formal deduction, as well as inductive observations". According to that explanation, we can conclude that mathematical reasoning is the proccess of thinking about mathematics which can take many forms, they are justification and use of mathematical generalization, make conclusion from assumptions and definitions.

Mathematical reasoning have some component. According to NCTM[1], Instructional programs from prekindergarten through grade 12 should enable all students to

1. recognize reasoning and proof as fundamental aspects of mathematics;
2. make and investigate mathematical conjectures;
3. develop and evaluate mathematical arguments and proofs;
4. select and use various types of reasoning and methods of proof.

Ball and Bass[6] state that "there are two key practices involved in mathematical reasoning – justifying and generalizing – and other mathematical practices such as symbolizing, representing, and communicating, are key in supporting these". According to English[8], nowadays, mathematical reasoning is viewed as gathering evidence, analyzing data, making conjectures, constructing arguments, drawing and validating logical conclusion, and proving assertions. Moreover, English[8] stated that "the ability to see connections and relationships among mathematical ideas and to apply this understanding to the solution of new problems is a basic component of mathematical reasoning". According to that explanation, we can conclude that the components of mathematical reasoning are

1. make conjectures
2. develop and evaluate mathematical arguments and proofs

3. generalizing
4. draw conclusions from evidence

B. Analogical Reasoning

Fathima[2] described reasoning as a thinking process, including the ability to interpret various forms and concept formation. So we can conclude that the reasoning is a process of thinking that organizes knowledge to make a new form, concept or a conclusion. There are several kinds of reasoning, one of which is inductive reasoning. Inductive reasoning is a process of generalizing the principle or a conclusion based on the specific facts that exist[2]. One kind of inductive reasoning is analogical reasoning.

Spiers[9] defined analogy as a set of problems which contains the initial problem and the target problem, where each problem has a relevant knowledge or information that can be mapped from the initial problem to the target problem. According Keraf[10], the analogy is comparing two things that have a lot in common. Gentner, Holyoak & Kokinov[8] defined analogical reasoning as one of reasoning ability by using the relationship of a pattern, include the ability to find patterns, identify repeat pattern with variations of each element, concluded from the patterns and communicate their conclusions as the goal of the proccess. Basically, analogical reasoning is the part of cognitive abilities and closely linked with someone's representation ability.

According to those opinions, we can conclude that the analogy is compare a few things based on the similarity or difference. Analogical reasoning is a process of thinking that aims to get a conclusion or new knowledge by using analogy or comparison between analogical objects with the prior knowledge about something. There are two types of the problem which use analogical reasoning.

1. Classical Analogy

Classical analogy, a type of analogical reasoning, involving some similarities in the nature of things, at least from the 4 things that will be compared. These linkages between the A and B terms and between the C and D terms[11]. The relationship in classical analogy is usually denoted by A: B :: C: D, which means the relationship owned A and B is similar to the relationship that is owned by C and D. There are two types of relation between terms in classical analogy, there are "lower order relation" and "higher order relation".

English[8] provides an example of the "higher order relation" in classical analogy is in branches: tree :: hand: human. The relation can be found between the branches of trees is similar with human hands**,** which branches are parts of a plant, as well as a hand which is part of the human body. The examples of the "lower order relation" in classical analogy is in goats: lung :: fish: gills. The relation can be found between goat and lungs is similar with fish with gills, the goats have lungs that function as a respirator, so do the fish, have gills that serves as a breathing apparatus.

According to English[8], there are three phases which always passes in classical analogy,

a. encoding phase. There is a process of identifying each object analogy to assess the properties or characteristics of each given object analogy. In this phase, the characteristics of each object analogy would be identified and the possible relationships between objects analogy;
b. infering phase. There is the process of comparing a pair of things that become the factor of analogy to determine the relationship between each object analogy. In this phase, we identified the possible relationship of each pair of given object analogy. In this phase, it is possible to appear more than one relationship between object pairs analogy can be identified;
c. applying phase. There is the process of generalizing or selection of the most appropriate relationship to complete an analogical process. In this phase, some relationships obtained in infering phase will be choose one of the most appropriate as a relationship. It will be used to determine the object analogy to complete the process of analogical reasoning.

Lunzer[8] have done a research which related with mathematical reasoning. In his research, Lunzer represents the classical analogy into a mathematics problem that includes three pairs of given objects analogy and an object analogy to look for a partner based on the relationship analogy indicated by three pairs of objects analogy that has been given.

Example question adapted from the classical analogy questions used in Lunzer research is:

18:12; 27:18; ?: 6; 24:16

What number is the most appropriate to fill the question mark?

In this case, we can refers to three phase in classical analogy by English[8] and identified how the reasoner thinking when solving problems, among others:

a. Encoding phase.

   In this phase, reasoner thinking about the characteristics of each number of the object of analogies and possible relationship.

   Suppose that when attention to numbers 18, 27 and 24. reasoner may identify some linkage between numbers, such as 18 and 27 are both multiples of 9 consecutive numbers, 18, 27 and 24 numbers are divisible by 3 or may arise identifying the nature of the other. Likewise, when attention to numbers 12, 18, 6 and 16. It is possible to identify some linkage reasoner numbers, such equally an even number, numbers 12, 18 and 6 is the number that is divisible by 3 or might appear identifying other properties.

b. Infering phase.

   In this phase, reasoner began comparing each other factors that have been identified in the encoding process.

   For example, the relationship 18:12 and 27:18. Reasoner possibly find the difference between the two pairs of these numbers, which is the difference between 18 and 12 is 6 and the difference between 27 and 18 is 9, so it is possible reasoner concluded that the relationship of the two pairs of these numbers are multiples of three consecutive numbers.

   Other relationships may arise between the 18:12, 27:18 and 24:16. One of them saying the numbers are added to the product terms 3 and 2, ie 6x3: 6x2, 9x3: 9x2, 8x3: 8x2, so it is possible reasoner concluded the pair's relationship of these numbers are the numbers that are on the left and the number that appears to the right has a fixed value ratio, which is 3: 2.

   In addition to the two relationships above, it is possible reasoner find other relationships between numbers.

c. Applying phase

   In this phase, reasoner seek the most appropriate relationship with the numbers of analogical objectwith several possible relationships that have been found in the process infering.

   For example, for the first relation, we can substract the number in each pair of the number to find the difference. In this connection, it is possible reasoner think that the right number to fill the question mark is 18, obtained from the sum of 6 and 12 as a difference in the next number. But in the next pair of the numbers, the difference between 24 and 16 are 8, not 15. So it can’t be concluded that the first possible relationship of the number can not be used to complete the analogical reasoning problem.

   For the next possible relationship, that each pair of numbers has a consistent comparisons, which is 3: 2. If the object of the right is 6 that can be expressed in the form of multiplication by 2 is 3x2, number 9 is obtained by multiplying 3 by 3 as numbers can be used to fill the object analogy to the left. Since the three pairs of these numbers qualify the relationship, then the relationship is the right relationship in analogical reasoning problem. So, the answer of the analogical reasoning problem is 9.

2. Problem analogies

Problem analogies is used to determine an analogical reasoning ability in problem solving. This type of analogy depends on the solved problem to solve new problems that become a target problem[11].

Problem analogies is presented in the form of word problems. To solve the problems of the target, we must know how the first problem, initial problem, has been solved. The steps to solved the initial problems then be applied to the next problem, the target problem[8].

The example of problem analogy that has been written by the English[8] is: “Sarah has 52 books on her self. Sue has 4 times as many as Sarah. How many books has Sue? If Mary has72 books and it 3 times as many as Peter has, how many books has Peter?”. To solve this problem, the number of Peter books resolved by the number of Sue books. Having obtained the completion of the initial problem, with the same procedures, concerns about the number of books Peter can be completed.

According to Clement[12], there are four phases which always passes in problem analogies.

a. generating the analogy, is the process of representing the conditions and possibilities of compatibility between the initial problems with the problems of the target. Reasoner identified the suitability of the things that are given as initial conditions in the initial problem and the target problem;
b. evaluating the analogy relations, is a process to re-examine, with the detail, the suitability of analogical relation between the initial problem with the target problem and determine appropriate analogical relation between the two object of analogy. In this phase, reasoner doing more detailed analysis of the relation or suitability of the problems which has been found in the stage of generating the analogy to identified the coresponding problem in the initial and target problems;
c. understanding the analogy case, is the process of testing and analyzing each component in the initial problem to understand the target problem. In this phase, reasoner analyzed the method used to solve the initial problem and the suitabilityof the initial problem with the target problem to determine the right method which is used to solve the target problem;
d. transferring findings, is the process of transfering the suitable conclusion or method which is used to solve the initial problem to the target problem. In this phase, the target problem solving by the method which is obtained in the understanding the analogy case phase.

C. Learning Mathematics

The ability of each student to learn actively is determine how the student obtain the purpose of learning. Hewitt[13] stated that "learning is an active process of constructing knowledge." This definition implies that learning is a process that is done by the students in constructing their own knowledge. Joice, Weil, and Calhoun[14] stated that "Learning is the construction of knowledge. In the process of learning, the mind stores information, organizes it, and revises previous conceptions. Learning is not just a process of taking in new information, ideas and skills, but the new material is reconstructed by the mind ". Learning is an activity to construct knowledge. Learning is consists of saving information activities, organize and refine their prior knowledge. Learning is not only a process of receiving information, ideas or new abilities, but also how the new knowledge constructed. Based on the description above, we can said that learning is an activity in which students actively build their own knowledge to achieve a competence, skill and a certain attitude.

Learning process occurs in students mind and the results of the learning process are the performance or product which is produced by the students. Nitko & Brookhart[15] stated that "instruction is the process you use to provide students with the conditions that help them Achieve the learning targets". From these opinions, we can said that learning is a process used to help students achieve their learning targets. Dick, Carey, and Carey[16] stated that "instruction is that it is a systematic process in the which every component (i.e., teacher, learners, materials, and learning evironment) is crucial to successfull learning". Learning is an activity that involves teachers, students, learning materials and learning environment to achieve the purpose of learning. Based on of those explanation, we can concluded that learning is a process that involves students, teachers and teaching materials. It is aimed to construct students knowledge by theirselves to achieve the purpose of learning. Suherman[17] defined the learning process as an educational

ISBN 978-602-74529-0-9

process within the scope of the school. Mathematics as one of the subjects taught in school, the curriculum of Elementary and Secondary Education, is a school mathematics[17]. School mathematics consists of the parts of mathematics which is chosen to develop abilities and personality of students. Based on principles and standards for school mathematic proposed by the NCTM[1], the study of mathematics should be able to equip the students in achieving the five standards process namely problem solving, reasoning and proof, communication, connection, and representation. Based on these standards, learning mathematics is not just activity to memorize formulas or perform calculations.

III. Discussion

A. Relationship between mathematical reasoning and analogical reasoning

It has been explain before that the components of mathematical reasoning are make conjectures, develop and evaluate mathematical argument, generalization, and draw conclusion from evidence. Now we will discuss about how mathematical reasoning can be developed through fostering student's analogical reasoning ability.

One of the type of analogical reasoning is classical analogy. As stated before, there are three steps of classical analogy. When students do classical analogy about mathematics, they must use those three steps. In encoding and infering steps, they may see some relation that match the analogical object. Of course in this case these relation is about mathematics. Then, they must make conjencture which relation that really match the pair of analogical objects. Afterwards, they must evaluate their arguments why that relationship is correct. Then, they must draw conclusion to decide what relationship the most correct. So, when students do classical analogy about mathematics, they use their mathematical reasoning. It means while students do classical analogy about mathematics, they use and develop their mathematical reasoning.

The other type of analogical reasoning is problem analogies. There are four steps in problem analogies. It means when students do problem analogies about mathematics, they must do those four steps. When they do generating the analogy step, they must think all of the possibilities of compatibility between the initial problems with the problems of the target. In this step, they must make conjecture about what relationship that match. Then, as they do evaluating the analogy relation step and understanding the analogy case step, they must evaluate their conjecture that have made before. Afterwards, they do transferring finding steps. In this step, they must make conclusion from the evidence that have been gahered. From those explanation, it means when students do the problem with analogical reasoning about mathematics, the also use their mathematical reasoning. So, using analogical reasoning when learning mathematics will help students develop their mathematical reasoning

B. Learning mathematics using analogical reasoning

Based on theoretical studies, it was concluded that the analogical reasoning is a thought process that aims to get a conclusion or new knowledge by way of analogy or comparison between objects with the knowledge that has been there before. In mathematics, we can use the analogical reasoning in the learning process. Not only in the process of transfer of knowledge, but also use to reinforce the concept that has been given to the students. Here's an example of instructional design of learning mathematics using an analogical reasoning.

1. Preliminary Activity

   In preliminary activity, we can use the analogy reasoning in apperception phase. In this activity, the teacher can show the relationship of the material prerequisites or their prior knowledge to the material they will be learning, then asking them to give a similar example. In this case, we use the principle of analogy reasoning is about two things that have similar properties. Students are asked to give an example of a problem that is almost the same or may be similar to that given by the teacher.

2. Core activities

In core activity, teachers can use some types of problems that involve reasoning analogy in the process of transferring knowledge. The teacher can providing stimulus material to students using the analogy of classical or analogy problems. For example in the study of geometry in grade VIII, we can take advantage of a classical analogy to direct students find the concept of giving name of prism. Teacher can give some pair of the picture of prism with different base side and their name. And then, teacher give the picture of prism with n-side and ask them to give the name of that prism. Moreover we can take advantage of the problems of analogy, to lead students to find a concept to define the terms of a general formula for the surface area of prism-n.

It just an example for using two kinds of analogical reasoning. Moreover, we can give the problem and the solution, more times, and then give a problem to the student which isi analogous with example problem and then ask them to solve the problem based on the example. It use the principal of analogy, that compare two things that have the similarity.

3. Closing activity

In the closing activity, we can use the analogy of reasoning in the stabilization phase of the material they have learned. We can provide exercises using the two types of analogical reasoning above to reinforce the concepts they have learned.

IV. CONCLUSION

Analogical reasoning and mathematical reasoning has strong relationship. Mathematical reasoning can be developed through fostering student’s analogical reasoning ability in learning process. Analogical reasoning can be used in preliminary activity, core activity, and closing activity in learning mathematics. When students do classical analogies and problem analogies in learning mathematics, students use the components of mathematical reasoning. It means by using analogical reasoning, students mathematical reasoning can be developed.

Undergraduate Student's High Order Mathematical Thinking Abilities Through Lesson Study Activities

Risnanosanti
Program Studi Pendidikan Matematika
FKIP Universitas Muhammadiyah Bengkulu Indonesia
e-mail: nosantirisna@gmail .com

Abstract—The purpose of this research is to develop lesson study learning activities aiming to improve undergraduate students' high order mathematical thinking abilities. This paper is intended to describe the learning activity-based on lesson study to improve student mathematical communication and problem solving ability. This research involved 36 students who take analytic geometry courses. This research is done by using the steps in activity-based on lesson study. Implementation of the research took place in four cycles. Each cycle consisting of activities plan, do and see. The instrument used are the observation sheet, instructional videotape, student worksheets, test for mathematical problem solving and communication ability. Analysis on data revealed that the undergraduate students' high order thinking ability especially in mathematical problem solving and mathematical communication increased significantly. By analysis, undergraduate students' mathematical problem solving, and mathematical communication ability was categorized good. Students already have the ability to analyze a given problem and make a plan how to solve the problem and then solve it as planned. Completion obtained through reflected in the classroom discussions.

Keywords: *mathematical communication, mathematical problem solving, lesson study*

I. INTRODUCTION

Issues concerning about mathematical thinking are one of the fundamental goals of mathematics curricula and instruction. One of the ability that need to be mastered mathematics student teachers is mathematical problem solving ability. According to NCTM [1]standard for mathematical problem solving ability mathematical learning programs should enable students to: build new mathematical knowledge through problem solving; solve problems that arise in mathematics and in other contexts; implement and customize a variety of appropriate strategies to solve problems; and monitor and reflect on the process of problem solving in mathematics. Solving ability is an integral part of learning mathematics. As noted Ruseffendi[2] that the problem-solving ability in mathematics is essential, not only for students who would later explore or learn math, but also for students who will apply it in other areas of study and in everyday life.

Besides having the mathematical problem-solving ability, ~~of~~ students should also be able to communicate mathematical ideas student had verbally and in writing, students must be able to interpret and evaluate the problems that arise so as to obtain the appropriate trouble shooting. Capabilities that support mathematical problem solving ability is called mathematical communication skills. So in order to become a perfect problem solver, student must have good mathematical communication

Students will have good ability to problem-solving and mathematical communication if both of these capabilities are continuously trained on learning activities in the classroom. The quality of learning that can facilitate to develop students' ability and can be done with the planning, implementation and evaluation of learning activities in a sustainable manner. One way of improving the quality of continuous learning is by conducting lesson study. Lesson study is an approach to improve the quality of learning that applies the concept of learning communities from each other to increase knowledge. Events

ISBN 978-602-74529-0-9

Calendar[3]defines the lesson study as a method of analysis of the case in practice learning, which aims to help the professional development of teachers and lecturers as well as an opportunity for teachers to learn from each other through the learning activities in the classroom. In lesson study activities, teachers can use a variety of learning models that correspond to the learning material or conditions that will be done. One of these is the model of learning problem-based learning.

A. Mathematical Problem Solving

Intellectual abilities are classified based on the level of complexity and is composed of the simplest mental operations to the most complex level. Problem solving is one type of intellectual skill rank higher and more complex than other types of intellectual. According to Kirkley [4] mathematical problem solving involves higher level thinking skills such as visualization, association, reasoning, manipulation, abstraction, analysis, synthesis, and generalization. The term “problem solving” refers to mathematical tasks that have the potential to provide intellectual challenges for enhancing students’ mathematical understanding and development. NCTM [1] stated that problem solving as a process that encompasses the entire process of teaching-learning provides skills about a contextual concepts.

Solving problems involving varying contexts derived from the linking problems in daily life situations posed mathematics. Students can solve some of the problems posed to them by others. However, it is easier for them to formulate their own problems based on personal experience and interest. The importance of problem solving ability, namely: (1) the ability of problem solving is a general purpose teaching of mathematics, even as the heart of mathematics, (2) solving the problem can include methods, procedures and strategies or ways used is a core process and major in mathematics curriculum, and(3) solving the basic skills in learning mathematics. Through problem solving, students will have the basic capabilities that are more meaningful in thinking, and can make strategies for the completion of further problems. Polya [5] describes in detail the four steps in solving problems, which are presented in sequence, namely: (1) understanding the problem (2) devising a plan (planned completion), (3) carrying out the plan (implement the plan), and(4) looking back(to re-examine the process and outcomes).

For the purposes of this study is a mathematical problem-solving ability is the ability to identify the elements that are known, asked, and the adequacy of the required elements; able to make/prepare mathematical models; can choose and develop coping strategies; able to explain and verify the answers obtained. To measure the ability of solving mathematical problems required several indicators. In this study, to measure the ability of students' mathematical problem solving test given in the form of questions about the material being taught. According to Turmudi [6] The indicator shows the mathematical problem-solving ability in this study are as follows.

1. Demonstrate understanding of the problem, including the ability to identify the elements that are known, asked, and the adequacy of the required elements.
2. Ability to create/construct a mathematical model, includes the ability to formulate problems of everyday situations in mathematics.
3. Select and develop coping strategies, including the ability raises various possibilities or alternative means of solving formulas or knowledge which can be used in solving the problem.
4. Able to explain and verify the answers obtained, including the ability to identify errors of calculation, the use of a formula error, check the compatibility between that have been found with what is being asked, and can explain the truth answers.

B. Mathematical Communication

Hulukati [7] said mathematical communication refers to the ability to use mathematical language to express mathematical idea and arguments precisely, concisely and logically. It helps students develop their own understanding of mathematics and sharpen their mathematical thinking. Mathematical problems solving that have been discussed previously closely related to mathematical communication. Students who already have mathematical problem solving ability are required also to be able to communicate, so that understanding can be used by others. With the students' mathematical communication skills can also take advantage of the mathematical concepts that are already understood others. By communicating mathematical ideas to others, one can improve mathematical understanding. Huggins[6]that in order to improve the mathematical conceptual understanding, students can do to express mathematical ideas to others.

Mathematics is the language of symbols in which everyone who studied mathematics required to have the ability to communicate using language symbols. Mathematical communication skills will make a person can use mathematics for its own sake as well as others, so it will increase positive attitudes towards mathematics both from within themselves and others. Sumarmo [7] suggested that mathematics as a language of symbol simple that mathematics is universal and can be understood by anyone anytime and anywhere. Each symbol has a clear meaning, and agreed to be shared by everyone. For example, the symbol '9', the operation +, - apply nationally each school level wherever that maybe understood by everyone.

Communication ability can support another mathematical abilities, such problem-solving ability. With good communication skills, students can be represented faster properly and this should be supportive for problem-solving. Hulukati[8] states that communication skills is a prerequisite for solving mathematical problems, which means that if students are not able to communicate properly interpret mathematical problems and concepts he can't resolve the problem well. In this regard, Pugalee[9] stated that in order for students to trained mathematical communication skills, the learning of students need to get used to give arguments on each answer and provide feedback on the answers given by others, so that what is learned to be more meaningful for him.

Mathematical communication can be developed in various ways, among them through group discussion. Within Saragih [10] suggests that the ability of communication becomes important when the discussion among the students performed. In the discussion, the students are expected to declare, explain, describe, listen, inquire and cooperate so as to bring the students to a deep understanding of mathematics. Therefore while students communicate their knowledge, they can lead to renegotiation between students' responses, and the role of the teacher is expected only as a filter in the learning process.

Students' mathematical communication is the ability of describing an algorithm and a unique way of solving the problem, the student's ability to construct and explain real-world phenomena serving as a graph, words/sentences, equations, tables and serving physically or ability of the students to give the all edged geometry images.

Mathematical communication are: (a) the central force for students in formulating concepts and strategies; (b) capital for student success and completion of the approach in the exploration and investigation of mathematics; (c) a place for students to communicate with their friends to obtain information, share thoughts and discoveries, brainstorm, assess and refine ideas to convince the others. Broader understanding of mathematical communication proposed by Rombergand Chair(in Sumarmo) [7], namely: (a) connecting real objects, drawings, and diagrams into mathematical ideas; (b) explain the ideas, situations and mathematical relationships orally or in writing with real objects, images, graphs and algebra; (c) declare a daily occurrence in the language or mathematical symbols; (d) listening, discussing, and writing about mathematics; (e) read with understanding a mathematical presentation of written, making conjectures, formulate arguments, formulate definitions and generalizations; (f) explain and make inquiries about the mathematics they have learned.

Baroody[11] suggests five aspects of communication, the five aspects are:

1. Representing, made are presentation means making another form of an idea or a problem, a tabular represented in the form of a diagram or better.
2. Listening, aspect of hearing is one very important aspect in the discussion. The ability to listen to the topics being discussed will affect the student's ability to give an opinion or comment.
3. Reading, the reading process is a complex one, because it related aspect to remember, understand, compare, analyze, and organize what is contained in the passage.
4. Discussion, in the discussions students can disclose and reflect his thoughts related to the material being studied. Students can also ask things that are unknown or still undecided.
5. Writing, writing is an activity performed by the conscious mind to reveal and reflect, as outlined in the media, whether paper, computers and other media.

In this study, mathematical communication skills will be measured through students' ability to express mathematical written communication skills in mathematical problem. In any mathematical problem, measuring communication skills in writing made by the indicators are: the ability to express and illustrate the mathematical ideas in the form of mathematical models that form equations, notation, pictures and graphics, or vice versa.

C. Learning Based on Lesson Study Activities

Students' mathematical thinking ability can be developed through training and habituation carried out repeatedly and continuously. In order to help students have mathematical thinking ability the teacher must be designing a learning process that potentially motivates students to be confident about their ability to solve the problem. Unfortunately the teachers lack of the idea to design learning process when they doing alone. Therefore, teacher can collaborate with another teacher to design learning process. When teachers coming together to design the learning process this activity namely lesson study. Lesson study is a potent embedded peer to peer professional learning strategy. According to Isoda, Stephens, Ohara and Miyakawa [12] lesson study is a process by which teachers of mathematics at several schools in the same community work together to research teaching materials, develop plans (lesson plans) and practice teaching lesson. In lesson study a group of teacher involved collaboratively planning, teaching, observing, and analysis learning and teaching in a research lessons. Lesson study is a scientific activity for teachers who want to develop their student ability, especially in mathematical thinking ability.

Lesson study is recognized with many features one of them is lesson study process or cycle. According to Sato [13] in Indonesia lesson study introduced as an activity consisting of plan-do-see

II. RESEARCH METHOD

This study is a qualitative descriptive study of learning done following the steps in the lesson study activities, This research was conducted in the second semester of the academic year 2013/2014, in Mathematics Program in Faculty of Teacher and Training, University of Muhammadiyah Bengkulu. The subjects were students of fourth semester who took analytic geometry course. Number of students involved is 36. Implementation research is conducted through the stages of the lesson study activities consisting of 4cycles. Each cycle has the following stages.

1.Plan

At this stage, the lecturer models to collaborate with some of the faculty observer to design learning is done by discussing determine the issues to be given to the student. Student centered learning designed with cooperative setting. Learning tool compiled and discussed to be fixed so as to minimize the existing deficiencies. The device is composed of student worksheet, observation sheet for learning activity and mathematical problem solving and communication test

2.Implementation(Do)

Activity at this stage is, lecturers models implement learning activities in accordance with the design that was created earlier. Observations carried out by a team of observers to observe the course of learning.

3.Reflection(See)

At this stage of reflection, lecturers discuss the model and the observer back to discuss the results of the observation of the observer. At this stage the model can be expressed lecturer difficulties encountered when implementing the learning activities. Lecturer observer provide findings that occur during learning activities take place. As the observers may have focused on different parts of the action, this has the advantage that the lesson is seen from several view point by a team who have the idea fresh in their minds.

Data collection in this study was done by

1. Observation

Observations conducted to collect data on learning activities, findings and students' ability in problem solving and mathematical communication. Filling in the form of a narrative observation sheet which can describe the picture of the learning process that occurs.

2.Documentation

Documentation used to obtain activity data plan, do and see through video recordings and written student work on the Student Activity Sheet.

3.Tests

Test scores are used to acquire problem solving skills and mathematical communication students after participating in learning activities.

Furthermore, the data obtained were analyzed qualitatively.

III. RESULT AND DISCUSSION

Result

Results and findings during the course of the lesson study is summarized by the indicators capabilities mathematical problem solving and communication. These indicators can be observed through the activities undertaken by the students during the learning process. Here will be presented the results of observations based on indicators of the problem solving and mathematical communication.

1.Mathematical Problem Solving Ability

Learning activities based on lesson study activities. In the learning activity models begin by reminding prerequisite the material has been learned and convey that learning activities done individually first followed by a discussion in groups and with the final class discussion.

a. Indicators Understanding the Problem

In the first open lesson learning activities begin with teacher give students an open problem related to outbound activities. The purpose of this materials to find the equation circle with a central at the point (a, b).

The problems identified are as follows:
At this stage of understanding the problem arises the opinions of students characterized as proposed by the group A: that the direction of the sun also determines the position of the hood, which means taking into account the displacement towards the north south east west if it is associated with the coordinate plane A rat nor this the direction of the positive y-axis, the south is the negative y-axis, the west is the direction of the negative x-axis and the east as the direction of the positive x-axis. So when there is a shift in the outbound playground will also affect the central of the circle. However, group B has a different opinion, students in this group said that the shift will not shift the playing field flag pole at the central so that the understanding of the game in the beginning of this group to the problem is to add distance to two times the game arena. This shows that students are trying to understand a given problem from the stand point of their own.

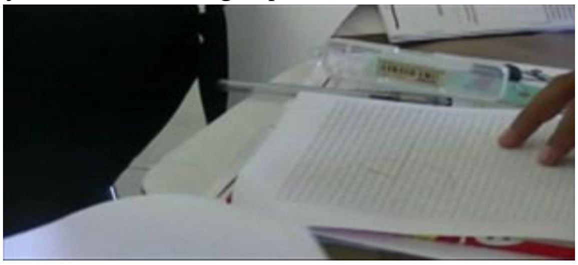
Students actively discuss in a group to understanding the topic

.b. Indicator Planning to Solve the Problem

Based on the understanding of the problem is given each planning group has different settlement. A group planning to shift the center of the circle in the direction of shift in the direction opposite to the direction of the sun so that the selected center is to the east. While group B planned completion by adding a second radius of the circle.

c. Indicators Implementing the Plan

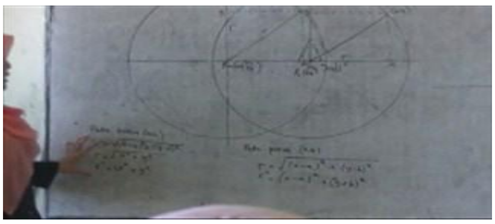
From planning made visible jobs results of each group as shown below:



Students made a plan to solve the problem

d. Indicators Check the Results of Solving Problem

At the time of the class discussion each group presented the results of his work and see if it is right or wrong. Lecturer models provide guidance through questions that dig so that students can summarize the results of solving the problem. The result of solving the problem is a circle equation that has the same radius of the circle in the center of the equation(0.0) but shifted the center of the circle. This shift though towards the right, left or up and down will still produce the same circle equation.



Students discussion their job for check the right answer

2.MathematicalCommunication Ability

Mathematical communication skills of students look when they perform well in group discussions and in-class discussion. Almost all students have dared to express his opinion as follows. Student A: That point was originally flag pole, after the sun high and hot atmosphere of the area game on the move with the same distance, the same fingers

Student B: between the first and second position of the same but the distance is summed so that his fingers womanly twelve.

Students already demonstrating that they have the ability to express mathematical idea, interpret and evaluate a problem and can be poured into a mathematical representation that corresponds to his thinking. It is a characteristic of a person who has the ability to reasonable good mathematical communication.

Observations indicate that the student already has the ability to problem-solving and mathematical communication even though there are still some students who have not been up involvement in learning.

Discussion

Students' can solve all of the problems that given by the teacher. This meant the students had high concentration on studying and learning activity more effective, thus the students could understand. In this case, if the students understand the lesson well, they will know the methods of solving the problems, then they will achieve in their study. If students have high activity in learning, their learning achievement will be absolutely higher than having poor activity while studying. Mathematical communication ability was both direct and indirect effect to mathematic problem solving by passing through students presentation. Mathematical communication ability affected the students' mathematic problem solving ability in a positive way.

IV. CONCLUSION

Learning that has been designed by faculty model and the observer was able to bring the train activity and problem-solving ability of students developing mathematical communication pretty well. From the results and discussion in this study it can be concluded that the learning models problems with cooperative setting in lesson study activities in the course of analytic geometry and space field can help the development of problem solving skills and mathematical communication students.

Analysis of Statistical Reasoning Process of Senior High School Students on the Size of Central Tendency

(The Case Study For Student's Low Math Ability)

Rosidah
Fakultas Matematika dan Ilmu Pengetahuan Alam (FMIPA)
Universitas Negeri Makassar
Email: Rosidah.unesa@gmail.com

Abstract- Reasoning is one of fundamental aspects of mathematics learning, it is as one of the necessary abilities of each student in the era of globalization that is full of challenges. The ability to reason is not only needed when students learn, yet very necessary when a person determine the decision. The aim of this article was to describe the statistical reasoning of high school students with low math skills to solve problems statistics. This research was a qualitative descriptive study. A qualitative approach is used to describe in depth how the reasoning process statistic subject to resolve issues related statistical measure of central tendency (mean, median, mode). The subjects were two students of class XI SMA Negeri 15 Makassar, with low math skills. It could be seen from the behavior of the subjects in completing written assignments are given, followed by in-depth interviews related to a given task. The research revealed that the subjects know the algorithm for calculating the average. At the stage of determining the median there was a difference perception between the two subjects, while the second mode related subjects had the same perception of the majority. At this analysis and interpretation stage, both of the subjects had not been able to interpret the statistical values obtained in accordance with the context well.

Keywords: *Statistical Reasoning, Senior High School, Statistical Problem, Low Math Ability*

I. INTRODUCTION

The functions of statistics as a science plays important role in all aspects of human life, as means to develop way of logical and scientific thinking . Statistics is used in order to collect, present, arrange, analyze and draw a conclusion mathematically. Ben-Zvi & Garvield [1] states statistical learning can be a tool to analyze the information or data, resulting from the information or the data can be taken the right decision in solving a problem.

Statistics as a part of a math lesson taught ranging from basic education to higher education require reasoning for such a study. Every day we face a variety of situations, problems or phenomena that has happened, is happening and phenomena that will occur, where most of the problems or phenomena in the form of a set of data and required thinking or reasoning for taking a decision in the face of these problems. Statistical reasoning plays an important role in dealing with situations, someone who is dealing with a set of data or events in everyday life. For example, when someone is watching television, reading newspapers or magazines, while active on the political activities or other social activities, often times the information obtained may be represented in various forms; e.g. graphs, tables, diagrams or combination of both.

At this time the statistics have been used in all areas of science, even been used by many giant companies of the world, e.g. Japan's success in applying the science of probability in designing and marketing a variety of products such as various electronic goods, cars, motorcycles and various other products. This accomplishment can be achieved due to the success of the Japanese education on the subjects of statistics given widely from upper secondary education to higher education. [2]

Related the importance of familiarization reasoning for students in the learning process of mathematics, Soedjadi [16] states: civilizing reasoning would be achieved if the effort to organize the reason that learners can run well so as to cultivate the habit of reasoning. By using the curriculum however reforming the reasoning required attention in the study of mathematics. It is becoming increasingly important in view of the future that is characterized by competition. In order to reasoning acculturation can be achieved, it is necessary that the presentation of mathematics in schools, both in the classroom and in textbooks, really directed to the structuring of reason.

In mathematics, as stated in the NCTM [14] it is expected that students will improve their ability in terms of reasoning (reasoning), problem solving, mathematical communication and in terms of using the mathematical representation. In the 2013 curriculum for all subjects are taught with the same approach that approach saintific through observe, to question, to reason, to try and form a network (here seems a shift of the students were told to the students to find out). It appears that the proficiency level on the reasoning aspects of the curriculum in 2013 is a very important thing, because if students are not developed reasoning ability, then for students of mathematics including statistical material will only be a matter that follow set procedures and emulate the examples without knowing its meaning.

The explanation above states that statistical reasoning ability is something that is sorely needed by the terms of the components of society, including students who take basic education to higher education which is the cornerstone of the nation's future in the future.

In this study the problem to be assessed is a matter of statistics. Completion of statistical problem is an important issue and needs to be studied, because it is through solving problems mainly related to the student experience in the daily life of students are expected to be skilled in identifying, selecting relevant knowledge in describing, interpreting the problem to make generalizations. However, in the study of mathematics in high school, statistics or mathematics problem solving cannot be done easily and quickly. To resolve these problems required reasoning.

Ability to solve problems related to mathematics and statistics is influenced by several factors, both internal and external factors. Internal factors include: interest, motivation, talent, intelligence and mathematical ability and gender, while external factors related facilities and infrastructure, curriculum, teachers, the media, other learning facilities.

The research result of Nurman [14] states that a student math skills affect the ability of mathematical problem solving. Students are capable of higher mathematics has high ability in solving mathematical problems, while students who have low math ability of mathematical problem solving ability are less good.

Based on the description above, the research questions that will be discussed in this article is "How does a statistical reasoning of eleventh year students who have the ability to lower the Mathematics Statistics in solving the problem?"

II. LITERATURE REVIEW

According to Ben-Zvi and Garfield [1]Statistical Reasoning as the way people reason with statistical ideas and make-sense of statistical information. This involves making interpretation based on sets of data, the representation of the data, or statistical summaries of the data. Statistical reasoning may involve; connecting one concept to another (e.g. center and spread), or it may combine the data and ideas about chance. Reasoning means understanding and being Able to explain statistical processes and being-able to fully interpret statistical results. "

Martin [5] defines the statistical reasoning as follows: "Statistical Reasoning as forming conclusions and judgments According on the Data from observation studies, experiments or sample surveys". From the definition above can be concluded that the reasoning statistically is the mental activity in connecting some of the concepts, facts, procedures in reaching conclusions that include describing, organizing, data reduction, represent the data, interpret and make sense of the ideas of statistics in the conclusion and be able to interpret the data which is obtained. Lovett { 5} claimed Statistical Reasoning involves the use of statistical ideas and tools to summarize the situation and draw assumptions and make conclutions from the data".

[8] stated statistical reasoning as a three-step process, among others:

1. Understanding (see particular problems as an issue)
2. Planning and implementation (to apply appropriate methods to solve the problem), and
3. Evaluation and interpretation (interpreting the results related to the initial problem.)

In practice, statistical reasoning involves being Able to assess how well the data are collected, describe the data, the draw Conclusions from the data, and allow for the UN- certainty that results from the use of a sample. Students, therefore, need to under- stand how sampling is influenced by the variation that is present in every process [6]

Garfield [9] states there are six reasoning goals for students: 1) reasoning about the data, 2) reasoning about representations of the data, 3) reasoning about statistical measures, 4) reasoning about uncertainty, 5) reasoning about samples, 6) reasoning about assosiation , In this research framework Jones et al [6] in assessing the statistical reasoning that high school students of class XI; describing the data; organizing and reducing the data; representing the data; and analyzing and interpreting data. There are two types of reasoning commonly incorporated into the statistical reasoning assessment instrument namely reasoning about the center and spread. Reasoning concerns about the data center analysis that involves the mean, mode and median. Meanwhile, spread involves reasoning about range, quartile, variance, and standard deviation.

Jones et al [6] suggest that in order to assess a person's ability to describe data (describing data) can be viewed on the ability of a person a) an accurate reading raw data or can show role in the form of tables, charts or graphs, b) demonstrate an understanding of convention elements graphics, c) have an understanding when given different views for the same data, d) evaluate the different views of the same data. Meanwhile, to assess a person's ability to organize and reduce the data (organizing and reducing data) are: a) Classify and sort the data, b) Recognize that there is information that may be lost in the segment data, c) Describing the data, the types of data and representation of data d) Describe the distribution data.

To represent data (representing data), [6] states that to assess a person's ability to represent data is:

a. Complementing the display of the data presented is not complete
b. Build the display of data representing different classification of the data set.

Jones et al [6] also stated that to assess a person's ability to analyze and interpret data (analyzing and interpreting data) is as follows:

a. Comparing and combining the data

b. Extrapolation and predict data.

Mooney [6] states: (1) describing the data e.g. tables, graphs, a list of which is looking for information explicitly stated in the display, acknowledge graphics conventions, and make a direct connection between the original data and display. This means that when describing data explicitly require the reading of the data presented in tables, charts or graphs representation; (2) organize and reduce the data associated with the process of organizing, categorizing, or consolidation of data in summary form; (3) represents the data associated with the data is displayed in graphical form. The process according to Groth (2003: 6) is able to make the display of data or an alternative view for a given set of data; (4) analyze and interpret data related to how to identify trends and make conclusions or predictions about the data.

NCTM [10] defines mathematical ability as "Mathematical power includes the ability to explore, conjecture, and reason logically; non-routine to solve problems; to communicate about and through mathematics; and to connect ideas within mathematics and between mathematics and other intellectual activity".

According to A.M. Blackwell [12], mathematical abilities are: "Mathematical ability indicates that Reviews These abilities can be interpreted as abilities for selective thingking in the realm of quantitative relationships (quantitative thinking) and for deductive reasoning, and as the ability to apply general principles to particular cases in the realm of numbers, symbols, and geometric forms "Meanwhile, according to G.Revesz [12] mathematical skills, namely: "Examines two basic forms of mathematical ability: Applicative (the ability to find mathematical relationships quickly intervening, without preliminary trials, and to apply the Appropriate information in analogous instances) and productive (the ability to reveal relationships that do not follow Immediately from the available information)"

A measure of central tendency is a single value that attempts to describe a set of data by identifying the central position within that set of data. As such, measures of central tendency are sometimes called measures of central location. They are also classed as summary statistics. The mean (often called the average) is most likely the measure of central tendency that you are most familiar with, but there are others, such as the median and the mode. The mean (or average) is the most popular and well known measure of central tendency. It can be used with both discrete and continuous data, although its use is most often with continuous data. The mean is equal to the sum of all the values in the data set divided by the number of values in the data set

Average is judged as measures of central tendency which comprised of mode, median, and mean by several statisticians. Nonetheless, average was interpreted in a different way based on problem context as argued by Konold & Pollastek [11], for instance fair share, data reduction, signal in noise, and typical value.

There are seven properties of average as declared by Strauss and Bichler [17]. The first property of the average is put between the extreme values and the second property is the summation of the deviations from the average is equal to zero. The third property is the average is affected by val ues except the average while the fourth property is the average is not primarily the same as one of the added values. The average could be a fraction that has no matching part in physical reality is the fifth property. The sixth property is the zero value ought to be considered when computing the average and the seventh property is the value of the average is indicative of the values that were averaged.

Furthermore, Mokros and Russell [13] found out five approaches to obtain the average that employed by the students from fourth, sixth and eighth grades including average as mode, average as algorithm, average as reasonable, average as midpoint, and average as mathematical point of balance. Those approaches were classified as two groups, i.e. approaches that do not view average as representative including average as algorithm and average as mode, as well as approaches that view average as representative including average as reasonable, average as midpoint, and average as mathematical point of balance.

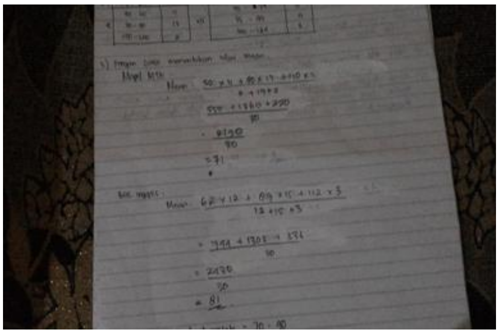
III. RESEARCH METHOD

This research applied a descriptive qualitative method, the research seeks to find meaning behind the symptoms or phenomena that occur. This study aimed to describe the statistical reasoning of eleventh grade high school students who had poor math skills. The approach used was a qualitative approach based on the grounds that this study met the characteristics of qualitative research, namely: (1) it was natural, that research was conducted according the actual circumstances in which the researcher as the main instrument, (2) the data was descriptive in the form of a series of words or image, (3) focus more on the process than the results, (4) the data processing tends to be done inductively, and (5) the main focus research is aimed at all the activities carried out individually [7]

The subjects of this research were students with low math skills. The process of collecting data in this study using a task-based interviews in which subjects were given the task of statistical reasoning (TPS), then the subject in asking reveal what he was thinking and asked to describe in detail his thinking process. Furthermore, do interviews and observations to explore the reasons, why take these conclusions and possible other solutions that could be done, including the unique things done by the subject when disclosing or submit comments. At the time of data collection, all activities performed research subjects recorded using audio and audiovisual recording devices, as well in the interview.

IV. RESULT AND DISCUSSION

Results based interview task of the two subjects on the collection of data describing the reasoning process of the subject on the size of the symptoms of the center when given the task of determining the average, median and mode were as follows: (1) At the stage of determining the average of the first subject using the formula average for grouped data in a way: first determine the subject of the largest and smallest values to determine the range, then create a table and specify the interval and determine the frequency of each interval. After that subject calculate the average value by multiplying the value of the center of each interval with a frequency followed by summing and further divided by the number of frequencies. This showed that a procedural subject can organize the data and know the algorithm for calculating the average, but when asked to explain the meaning of the average of the results obtained, the subject stated the average was mostly or at most. Here is the work of the first subject.



(The picture above was one of the student's work)

(2) At the stage of determining the Median of first subject and the second subject did not know the formula median for grouped data. But for the first single data subject can explain how to determine the median of the data even or odd numbers well, which was a way to first sort the data from the smallest to the largest data. If even then the data after the data burst, then the median was the middle of the two data divided by two, but if the data was odd, the data lays the middle was the median. Subject to the two states to determine the median is the same as determine the average. The results indicate that the two subjects into trouble and did not know the formula for a median of grouped data, but there were cognitive differences between the first and second subject of the median, where the first subject can distinguish how

to calculate the median and average. The median for the two subjects was the middle value. Here are excerpts of an interview with both of the subject.

Excerpts of an interview with the first subject:

Researcher : What is average?

Interviewee : Add and divide by the number

Researcher : What is the definition of average?

Interviewee : The most

Researcher : What is median?

Interviewee : The mid-point

Researcher : How do you determine the median?

Interviewee : If a single data in advance data is sorted from smallest to largest data

Researcher : And then?

Interviewee : If the data is an even number, the two most central data summed and then divided by two is the median, but if the data is odd, then the data that most middle after a median of data sequences.

Excerpts of an interview with the second subject:

Researcher : What is average?

Interviewee : Add and divide by the number

Researcher : What is the definition of average?

Interviewee : The most

Researcher : What is median?

Interviewee : The mid-point

Researcher : How do you determine the median?

Interviewee : Same way with an average

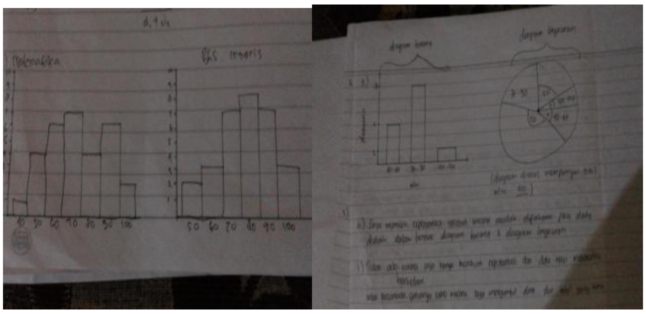
Researcher : Is there a difference in determining the average and median?

Interviewee : Different formula ma’am.

Researcher : Before using the formula, what should be done on the data?

Interviewee : Nothing ma'am, is the same as the average. To determining the median value I take the data center.

(3) Related to the second mode is the mode of the subject states that the value of most appear and younger determine the mode by looking at the highest bar chart. (4) In the phase represents the data in the form of charts or graphs, the first subject can represent data in the form of pie charts or graphs, while subject to the two cannot represent data, this may happen because they do not know how to draw a good diagram. (5) In the analyze phase and interpreting data in the two subjects have not been able to analyze and interpret every value-value statistic obtained in accordance with the context. This indicates that the subject has not been able to link her internal network when analyzing and resolving problems or represent data.



V. CONCLUSION

Based on the results obtained in this study, it can be concluded: in the reasoning process of describing the data students can identify the facts on the question asked, but requires the stimulus of researchers. The reasoning process of the students in organizing and reducing data is only the first subject that can sort and group the data appropriately. Statistical reasoning process of the subject in the data representing the first subject can be represented well in the form of charts and graphs, while the second subject cannot represent the data in the form of charts or graphs. Statistical reasoning process of analyzing and interpreting the subject in the second data subjects cannot draw conclusions and interpret the value statistic in context well. The second subject had a median-related reasoning is wrong with stating the average and median alike.

VI. SUGGESTION

Based on the above conclusions, it is recommended that some of the following:

1. In teaching statistics, high school teachers should use static reasoning stage, so that students can be trained reasoning as early as possible

2. In teaching mathematics and statistics teachers should pay attention to the reasoning process and designing a model student and learning methods by considering the mathematical abilities of students vary.

Facilitating Students From Inadequacy Concept in Constructing Proof to Formal Proof

Syamsuri[1], Purwanto[2], Subanji[2], Santi Irawaty[2]
[1] Department of Mathematics Education, University of Sultan Ageng Tirtayasa
[2] Mathematics Education Graduate Program, State University of Malang
syamsuri@untirta.ac.id

Abstract— This article aims to describe in correcting errors experienced by students in constructing mathematical proofs related on concept of numbers. Research was conducted on students who have taken Number Theory courses at the University of Sultan Ageng Tirtayasa Serang-Banten. The research data obtained by asking the students who have worked on the mathematical proof problems, then proceed with the interview-based questions. The focus of the discussion of this article is to correct errors in constructing proofs when students' answer is right at the first step of proof, but not connected with other mathematical concepts that support the proof. Based on this research, facilitating the student who has the inadequacy of the concept can be done through the following steps: 1) raise awareness that there is an error in constructing the proof, 2) encouraged to think of reflection, and 3) help to get directions or strategies of proof. The flow of the correcting process, starting with correcting concepts with examples, correcting the pattern in the form of formal logic, symbolization, and then inserting to Representation System Proof (RSP).

Keywords: *Proof Construction, Formal-proof, Inadequacy Concept, Awareness, Reflection*.

I. INTRODUCTION

The process of proving a mathematical proposition is a sequence of mental and physical actions, such as writing, thinking tobegin the proof, draw diagrams, to reflect on previous actions or trying to remember the example. The process of proof formation of a theorem of or statement is more complex than the proof itself [1]. Therefore, teacher is needed for facilitating in learning mathematics thus facilitate students in mathematical proofs. In mathematics, one of the teachers'aid to help the students in order to make it easy to perform mathematical proofs is to make it into a tangible proof [2]. So, teaching assistance on mathematical proof to the students can be done gradually and trying to create proof into something tangible.

Griffiths (in [3]) states that a mathematical proof is a formal and logical way of thinking that starts with axioms and moving forward through logical steps to arrive at a conclusion. Based on these definitions, provide properties that mathematical proof should be logical. Logical mean, it is accordance with the rules of inference so the conclusion is valid. Therefore, the processes that occur in constructing proofs are using the rules of inference from the known, which then connects with the facts or other mathematical concepts that lead to the conclusion that is intended to prove.

Research in improving mathematical proof by the students has been conducted by several researchers ([4], [5], [6],[7], [8]). Komatsu's research [4] on elementary school students and Komatsu et al. [5] to high school students, both were studying mathematical proofs by providing a problem to build a simple conjecture, then submit a counter-example of the problem. With a counter-example, students are encouraged to indicate whether the conjecture they built is right or wrong. Thus, correcting errors in constructing mathematical proofs can be done in various ways, so it can force the students to do reflective thinking. Selden and Selden [6] conducted a study about improving mathematical proof of the student by asking students to assess and validate the wrong mathematical proof. The result is the validation of proof done by the students can be effective in improving the learning of mathematical proof. This is because in validating the wrong proof, it turns out that the students were doing reflective thinking processes. Andrew's research [7], so that with such a device,studentsare capable of knowing their mistakes and hopefully will correct the error of the proof. Stylianides & Stylianides [8] revealed that the learning stages with Conceptual Awareness Pillars (CAPs) were able to aware students to the concepts associated with mathematical proof by giving the challenge in the form of a counter-example.

Preliminary research conducted by [9], schemes of students thinking in constructing a formal proof can be categorized and modeled in four quadrants student thought processes, namely: (1) Quadrant I, able to make correct think schema; (2) Quadrant II,the student who suffered concepts insufficiencies caused by not doing reflection so that the necessary concepts can be used completely; (3) Quadrant III, experiencing misconception due toinsufficienciesofprior knowledge and not knowing the correct proof steps(4) Quadrant IV, incorrect logic that caused by the prior knowledge of its use is not in accordance with the structure of the expected proofs. Therefore, there is a need for a study of the transition of students from Quadrant II, II and IV towards Quadrant I. Based on the above, this article aims to describe and correct errors experienced by students in the construction of mathematical proofs of Quadrant II to Quadrant I.

II. METHOD

The present study is qualitative research which aims at constructing proof. This of the six students who were used as research subjects, all students experienced errors in constructing the proofs above. Proofs construction made by students can be categorized into three types, namely: 1) right at the first step of proof, but wrong in connecting with the other mathematical concept that support the mathematical proof, 2) have not bring up the initial step of the right proof, so they are not capable to construct the proofs well, and 3)make mistake in the first step in choosing the proof method, so they are not capable to construct the proofs well. The focus of the discussion in this article is to correct errors in constructing proofs when students were right at the first step of proof, butwrong in connecting it mengoneksikan with other mathematical concepts that support the proofs.

Research was conducted to the students at the University of Sultan AgengTirtayasa who have taken Number Theory courses. Students were given the opportunity to work on the proof problems, and then proceed with the interview-based questions. The research subject is taken from the students who were right at the first step of proof, but wrong in connecting it with other mathematical concepts that support the proof. Analysis of data is using constant comparison techniques, which is taking two students who have characteristics with the similar mistakes in constructing a mathematical proof.

Instruments used are in the form of questions adopted from [8]. Here's the question: Given n as positive integer. Prove "If n^2 is multiples of 3 then n is multiples of 3". To demonstrate that improvement has managed to improve the proofs construction, students were asked to construct a proof of other similar problem, namely: Given n is positive integer. Prove "If n^2 is multiples of 5 then n is multiples of 5"

III. RESULTS AND DISCUSSION

Students who construct the proof in the initial step correctly, but wrong in connecting it with other mathematical concepts that support the mathematical proof, experienced by Students-F and Student-K. Here are the mathematical proofs along with the analysis of deficiency as the result of the thinking process of Student-F, as follows:

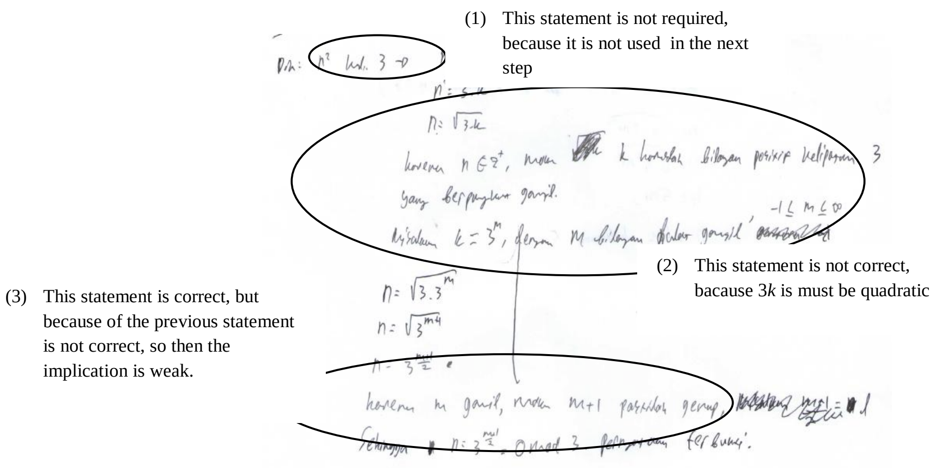

FIGURE 1. PROOF CONSTRUCTION OF STUDENT-F

Based on Figure 1 above, it appears that there is an inadequancy of the concept in the proof constructions of the Student-F. These inadequancy of the concepts occurred in inferring, looking for a relation with rank numbers. It should accommodate with the perfect squares numbers, but the Student-F make accommodations with rank numbers which is the rank of cardinal number 3 with the rank of an odd number. Therefore, efforts are needed to improve this wrong process. The wrong process is the result of lack of proper connection between n as positive integers with 3k which is the number in the root. This is what isasked to the Student-F as follows:

Researcher (R): Here the positive numbers k is the multiples of odd number, why choose odd number?

Student-F (F): Because if suppose it is even, then root-number is odd, And if odd then root-number is rational number

To track Student-F's understanding in constructing proof, carried out a series of questions that answered by Student-F as in Figure 2. That process started with an inquiry about numbers as an example that satisfies the theorem proved. Numbersas an example which is mentioned by the Student-F is 36. The number was able to create cognitive conflict in the Student-F's scheme of thinking, because he has to analyze that 36 = 3 x 12 = 3 x 4 x 3. In this way, it was able to bring Student-F to realize that there is an error in constructing the previous proof.

R:Should be it (odd rank)?, Earlier, it was for example 36…
F: 36 = 3 multiplied by.... 36 = 3 multiplied by 12.... Yeah Sir

By realizing his mistake, it makes the condition of disequilibrium in student-F's thinking scheme, which resultedan encouragement on Stundent-F to do reflection. Reflection is aided by asking which multiples of 3 is and making use the greater numbers as an examplewhich is a multiples of 3, namely 81 and 144. Student-F was able to analyze that $81 = 3 \times 3^3$ and $144 = (12)^2 = (4 \times 3)^2 = 3^2 x4^2$.

R: So how is the characteristicshould be..how k is should be ...?
F: [thinking ....]
R: Earlier you mentioned 36, try it now with ... 81. Try again what it means to be a multiple of 3?
F: It means, one of the factors is 3.
R: One of the factors is 3, yeah. Or simply, 12 ismultiples of 3 because of what....
F: 3 multiplied by a number, the result is 12.
R: 18 ismultiples of 3, it means..?
F: 3 multiplied by a number, the result is 18

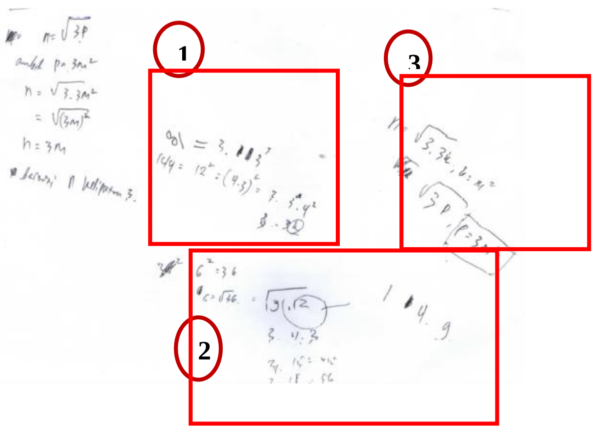

FIGURE 2. STUDENT-F'S IMPROVEMENT PROCESS IN CONSTRUCTING PROOF

Writing the number $81 = 3^2 \times 3^2$ and $144 = 3^2 x4^2$ can makeStudent-F able to read that there is a pattern of numbers that the square numbers multiples of 3 patterned 3^2 times another square numbers. So, Students-F makes the symbolism of the number pattern to be used in improving the mathematical proof construction.

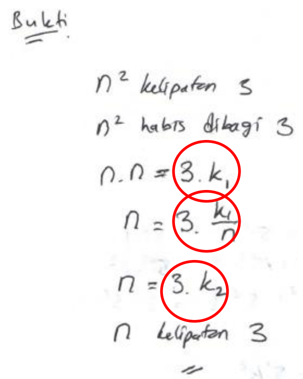
R: Now think of the form how should be like this(odd rank), whether it should be ranked or simply multiplied

ISBN 978-602-74529-0-9

F: Well.... (Thinking long enough) ... .3 multiplied by 3 times the square number, Means, n = root of 3p, p = 3m^2, meaning n = root of (3 3 m^2)
R: Why is p equal to 3 m^2, what is the reason?
F: First, n is positive number, integer, then 3 must be multiplied by 3 m^2, so if taking its root yields integer too
R: what is p?
F: p is integer

Based on the above, Student-F through the process in improving the proof construction begins by looking for the number n that satisfies the statement. It aims to reduce the degree of abstractness the statement proved. Furthermore, from the numbers that meet the requirement of the statement, he traced the pattern of numbers that appear. Then proceed with symbolyze the variable n, accordance with the pattern of numbers found in the previous step. Furthermore,he is symbolizing the inserted variables into the system that proovedearlier.

Furthermore, it will discuss about the mathematical proof along with the analysis of deficiency as the resultof the thinking processof Student-K.



1) Not declare that $k_1$is positive integer
2) Not declare that k_1/nis positive integer
3) Not declare that $k_2$is positive integer

FIGURE 3. PROOF CONSTRUCTION OF STUDENT-K

Based on Figure 3 above, it appears that the proofwhich is constructed byStudents-Khas an inadequancy on the concept. These inadequancy occurred in inferring when looking for a relation, in order the number *n* is 3 times a constant. However, the Student-K did not notice that the constants must be integers, so it makes division for k_1 divided by n to obtain a new constant. Therefore, it is needed an effort to improve the wrong process.

To track student-K's understanding in constructing proofs, it isconducted a series of questions that are answered as in Figure 4.

Researcher (R): Why Rohim dividing k_1 by n, here?
Student-K (K): For this sir ... So it can be in the form of multiplication by 3
R: The form k_1 / n, what kind of number is it?
K: Integer ... It's because the n is integer
R: Are you sure?
K: ... mmm ... mmm ....

The question turned out to be capable of generating cognitive conflict of thinking schemes in Student-K. This is indicated by the appearance of disequilibrium. Thus, the students are forced to think reflectively. In reflective thinking, to reduce the level of abstraction of the theorem, they are asked about the example that satisfies the theorem. The studentslisted some positive square numbers, and thenmentioned numbers 9, 36, and 81. Student-K connecting the three numbers with the numbers 3 and were able to read that there is a pattern of numbers.

Q: Is there a pattern?
K: [working ...]
P: Are you sure ...?
K: yes, sir. The pattern is$3^2.k^2$

Based on the above, student-K through the process in improving the proof construction begins by looking for the number n that satisfies the statement. It aims to reduce the degree of abstractness the statement proved. Furthermore, from the numbers that meet the requirement of the statement, he traced the pattern of numbers that appear. Then proceed with symbolyze the variable n accordance with the pattern of numbers found in the previous step. Furthermore, he is symbolizing the inserted variables into the system that prooved earlier.

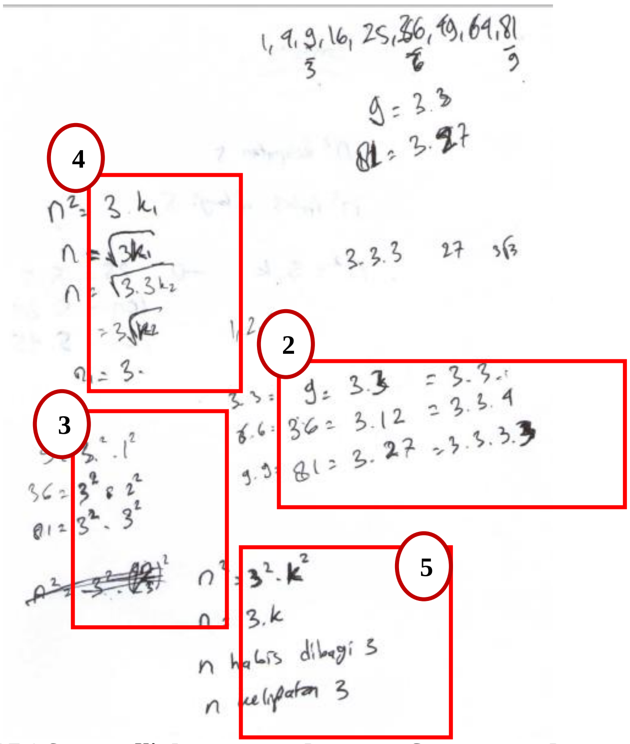


FIGURE 4. STUDENT-K'S IMPROVEMENT PROCESS IN CONSTRUCTING PROOF

Based on the discussion of the proof construction that was constructedbyStudent-F and Student-K, it can be obtained work-flow improvements as follows:

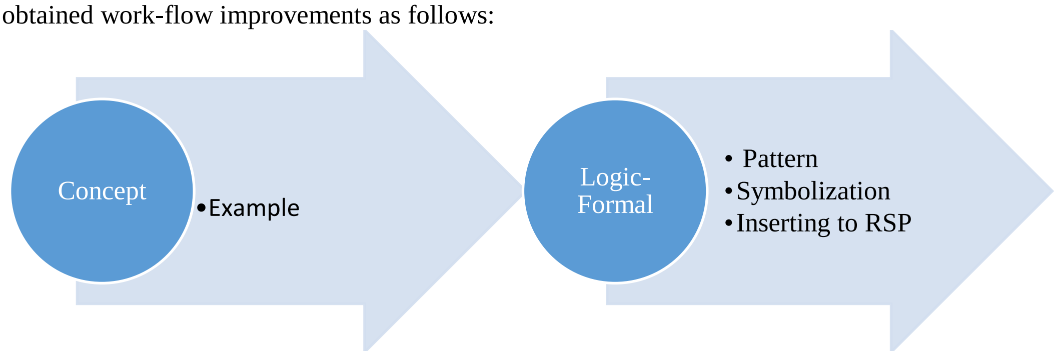

FIGURE 5. FLOW PROCESS IMPROVEMENT OF PROOF CONSTRUCTION FOR STUDENTS EXPERIENCING AN INADEQUANCYCONCEPT

IV. CONCLUSION

The research revealed that in order to correct mistakes in constructing mathematical proof for the students who are right at the first step of proof, but wrong in connecting with the other mathematical concept, can be done through the following steps: 1) raise awareness that there is an error in the proof that has been constructed, 2) encouraged to think reflection, 3) helping to get directions or proof strategies. The flow of the improvement processis, starting with correcting concepts with examples, and then correct the patter of formal logic, symbolization, and inserting to Representation System Proof (RSP).

Adaptive Reasoning Junior High School Students In Mathematics Problem Solving

Teguh Wibowo
Mathematics Education
Muhammadiyah University of Purworejo
Purworejo, Central Java, Indonesian
e-mail: teguhwibowoump@yahoo.com

Abstract- The purpose of this research was to determine adaptive reasoning on junior high school students grade VIII in mathematics problem solving. The method used is a qualitative method of data analysis techniques triangulation. The results showed adaptive reasoning students in mathematics problem solving are as follows: (a) formulate what is known of the mathematical problem given, (b) formulate the unknown, (c) formulate the terms in question, (d) identify strategies to solve mathematical problems, (e) be able to write formulas to help solve mathematical problems given, (f) found the final result of a mathematical problem, (g) write the conclusion of a mathematical problem, (h) write the reasons of the strategy being obtained, (i) write the reasons for their conclusion, (j) examine the solution back.

Keywords: *adaptive reasoning, mathematics problem solving*

I. INTRODUCTION

During this time the mathematics is still considered difficult to be understood by students. Although education is now growing quite rapidly compared with education antiquity, it is supported by the development of teaching aids and learning mathematics media that can facilitate students in understanding mathematics. In face of science and technology development so fast this time, the necessary human resources that are reliable and capable competent globally [1]. With competition so tight that each person required to develop the mindset associated with reason.

National Council of Teachers of Mathematics (NCTM) states that the purpose of learning mathematics is to develop mathematical communication skills, mathematical reasoning, mathematical problem solving, mathematical connections and mathematical representations [2]. Basically, every student is required to hold the mathematical purposes, but in reality, not all students are able to hold all existing mathematical purposes. This relates to the smoothness during the learning process takes place. But of all the goals that a student needs to hold one is about the mathematical skills of mathematical reasoning abilities.

Reasoning is a major component in mathematics. Ross in [3] saying that, that should be emphasized as a foundation in mathematics is reasoning, if reasoning ability is not developed in the students, then the mathematics will only be a problem for students while following a set procedure of learning and imitating the example without thinking about why math makes sense.

Reasoning is divided into several types, including adaptive reasoning, quantitative reasoning, intuitive reasoning, and there is still another reason. Students are said to be capable of adaptive reasoning when students are able to think logically about the existing problems, estimating the problem until students can conclude. Besides the adaptive reasoning there is a process in which a student is required to be able to give a reason for what the students have been working on. Adaptive reasoning also interacts with the process of understanding the other, especially in the problem solving process. Problem solving skills can be hold students well if students also hold the mathematics skills, one of which is the ability to adaptively reason.

Based on observations the author on one of the junior high scholl in Purworejo district, found that when students solve a problem, there are some students who can predict these problems until it can conclude and give the reasons of what the students do. But there are also students who can only infer a problem or otherwise, the student can only estimate it. This process is already leading to adaptive reasoning, but does not necessarily indicate that the student has developed adaptive reasoning to solve a mathematical problem. It can be concluded that the adaptive reasoning owned by students is very varied. This can be seen when students solve a problem, many ways in which students in solving the problem.

Research related adaptive reasoning had been done by [4], the results showed that male subjects tend to be less careful and thorough in solving mathematics story, it supports the skills to suggest that female are superior to male in accuracy, thoroughness, and exactitude of thinking. Based on the above, authors are encouraged to conduct research related to adaptive reasoning students in solving mathematical problems. The purpose of this study was to determine the adaptive reasoning junior high scholl students grade VIII in mathematical problem solving.

II. Adaptive Reasoning

Mathematics has a great relationship closely related to reasoning. Ministry of Education in [5] states that matter of mathematics and mathematical reasoning are the two things that can not be separated, ie, matter understood through reasoning and mathematical reasoning to understand and learn the material drilled through mathematics. Reasoning can also build mathematical understanding about what he saw, they think and they conclude in mathematical problem solving.

Mathematical reasoning according to Ball & Bass [3] are the basic skills of mathematics and is required for some purpose, to understand mathematical concepts, use of mathematical ideas and procedures flexible. Students who use reason ability in learning mathematics will find the learning of mathematics more meaningful, because the mathematical reasoning would establish a new relationship with the relationship that has been previously owned.

In mathematics there are two kinds of reasoning, inductive reasoning and deductive reasoning. John Stuart Mill stated that the induction of an activity in which we conclude that what we know to be true for special cases will also be true for a similar case for certain things [5]. While deductive reasoning is a way of drawing conclusions from statements or facts that are considered correct use logic. This reasoning tend to use theories or formulas that have been proven to be true deductively.

Adaptive reasoning included deductive reasoning conclusion withdrawal ways is based of facts which are true logician, and also includes inductive reasoning based on observation generalization of some cases. Adaptive reasoning refers to the ability to think logically about the relationship between the concept and the situation [6]. Meanwhile, according to [7], adaptive reasoning is the ability to think logically about the relationship between the concept and situation, ability for reflective thinking, the ability to explain, and the ability to provide justification. So it can be said that the adaptive reasoning is the ability to think logically about the relationship between concepts and procedures makes sense generalized manner, so as to demonstrate the possibilities in problem solving, as well as allow the differences of opinion must be resolved in a way that is reasonable.

Students are said to be capable of adaptive reasoning when students are able to think logically about the existing problems, estimating the problem until students can conclude. In the adaptive reasoning be a process in which a student is required to be able to give a reason for what the student has done. Adaptive reasoning also interacts with the process of understanding the other, especially in the problem solving process. Problem solving is a mental process and requires a high level of more complex thought processes including reasoning [8].

Some experts have proposed indicators to determine the adaptive reasoning students in solving mathematical problems. In this research the authors formulate indicators adaptive reasoning such that when the student is able to: 1) write an allegation of mathematical problems, 2) draw a conclusion of mathematical problems, 3) give the reasons for the outcome of mathematical problems, 4) to re-examine the results of the settlement, 5) finding algorithm on a mathematical problem.

III. Research Methods

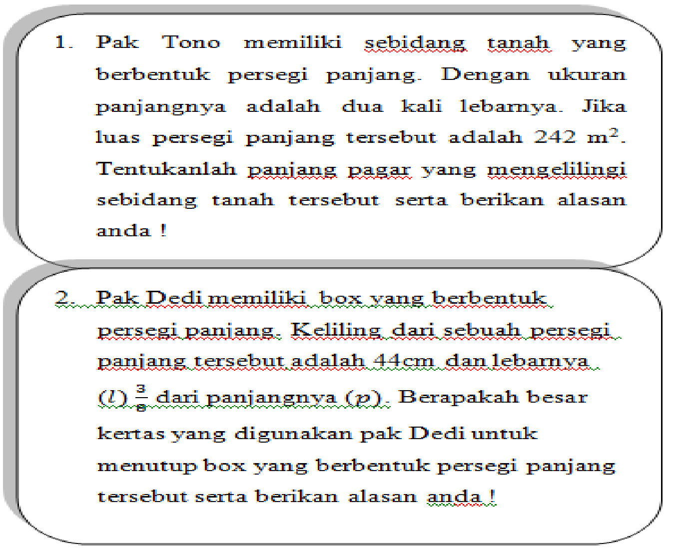
The research is a qualitative research with descriptive design. Descriptive is a collection of data in the form of words, pictures and does not contain the figures in it [9]. The study was conducted in September-November 2015 on the junior high scholl 4 Purworejo. Subjects were 3 students of grade VIII F ie students who can solve problems and have adaptive reasoning. Subject retrieval is done by purposive sampling and snowball sampling [10].

The instrument used consisted of the main instruments and supporting instruments. The main instrument is the researchers themselves, while supporting instruments is a matter of the test, the observation sheet and interview guidelines. Data collection is done by test, observation, interview techniques and field notes. Data analysis technique used is based on the model of Miles and Huberman [10]: (1) data reduction is choosing the data needed by researchers, the data reduction requires triangulation techniques, (2) data display, (3) conclusion.

IV. RESULTS AND DISCUSSION

In this research the researchers choose three subjects based on test results at an early stage. In this research, there are four forms of data at the time of the research activities taking place, that the results of the students' answers, the result of observation, interviews and the results of field notes. Four of these data will become a measurement to deduce how the adaptive reasoning in solving mathematical problems in grade VIII junior level.

Giving matter on the subject is done after school hours starting from 12:30 o'clock. The material was tested in the form amounted to 2 questions about the story with the material Quadrilateral. When students have completed work on the next step is an interview based on the results of the students' answers. By the time the students do the problems, researchers conducted observations and write field notes for further data. Under this problem sheet that I use in this study.



1. Pak Tono memiliki sebidang tanah yang berbentuk persegi panjang. Dengan ukuran panjangnya adalah dua kali lebarnya. Jika luas persegi panjang tersebut adalah 242 m^2. Tentukanlah panjang pagar yang mengelilingi sebidang tanah tersebut serta berikan alasan anda !
2. Pak Dedi memiliki box yang berbentuk persegi panjang. Keliling dari sebuah persegi panjang tersebut adalah 44cm dan lebarnya (l) $\frac{3}{8}$ dari panjangnya (p). Berapakah besar kertas yang digunakan pak Dedi untuk menutup box yang berbentuk persegi panjang tersebut serta berikan alasan anda !

Figure 1. Research Problem Sheet

The first phase is done by the students is to formulate what is known of the mathematical problem. This is shown by the results of the answers to the student in point 1 be presented in the figure below.

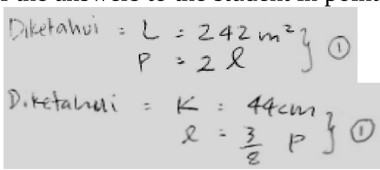


Figure 2. Writing Things to Know

The second phase is done by these students is to formulate the unknown of mathematical problems. This can be demonstrated by the results of the students' answers based on the question contained in point 2 of which will be presented in the figure below.

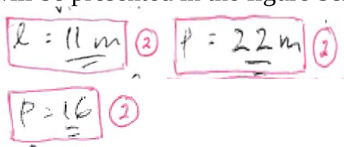

Figure 3. Formulate Things Not to Know

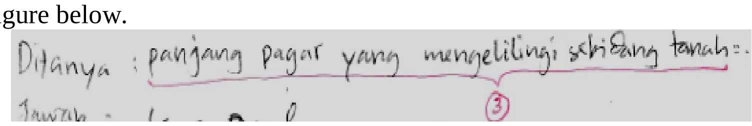
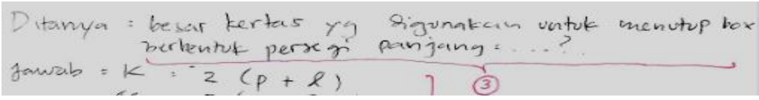
The third stage is done by these students are able to formulate the terms of those asked in a given mathematical problem. It can be shown in the results of the students' answers on point 3 which will be presented in the figure below.



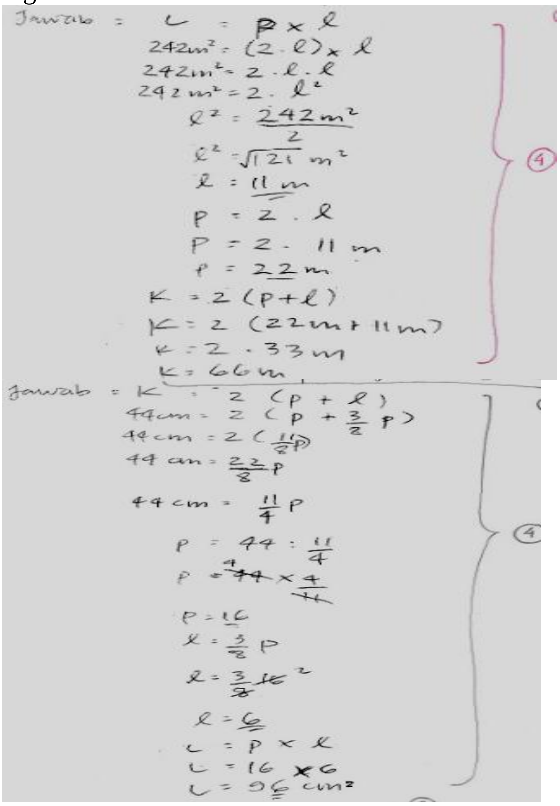
ISBN 978-602-74529-0-9



Ditanya : besar kertas yg digunakan untuk menutup box berbentuk persegi panjang : ... ?
Jawab : K = 2 (p + ℓ) ③

Figure 4. Formulate Asked Things

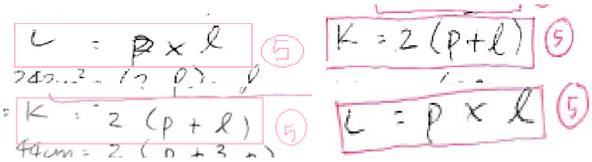
The fourth stage is done by these students are able to find strategies to solve mathematical problems given. It can be shown in the results of the students' answers are contained in point 4, which will be presented in the figure below.



Jawab : $L = p \times \ell$
$242 m^2 = (2 \cdot \ell) \times \ell$
$242 m^2 = 2 \cdot \ell \cdot \ell$
$242 m^2 = 2 \cdot \ell^2$
$\ell^2 = \frac{242 m^2}{2}$
$\ell^2 = \sqrt{121} m^2$
$\ell = 11 m$
$p = 2 \cdot \ell$
$p = 2 \cdot 11 m$
$p = 22 m$
$K = 2 (p + \ell)$
$K = 2 (22 m + 11 m)$
$K = 2 \cdot 33 m$
$K = 66 m$ ④
Jawab : $K = 2 (p + \ell)$
$44 cm = 2 (p + \frac{3}{2} p)$
$44 cm = 2 (\frac{11}{2} p)$
$44 cm = \frac{22}{8} p$
$44 cm = \frac{11}{4} p$
$p = 44 : \frac{11}{4}$
$p = 44 \times \frac{4}{11}$
$p = 16$
$\ell = \frac{3}{8} p$
$\ell = \frac{3}{8} 16$
$\ell = 6$
$L = p \times \ell$
$L = 16 \times 6$
$L = 96 cm^2$ ④

Figure 5. Finds Possible Settlement Strategy

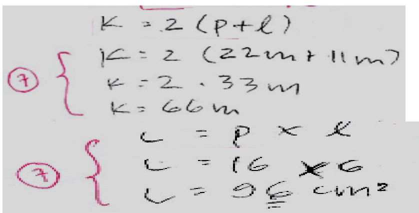
The fifth stage is done by these students are able to write the formula to help solve mathematical problems given. This can be demonstrated by the results of the students' answers on point 5 which will be presented in the figure below.



$L = p \times \ell$ ⑤ $K = 2 (p + \ell)$ ⑤
$K = 2 (p + \ell)$ ⑤ $L = p \times \ell$ ⑤

Figure 6. Writing Formulas

The sixth stage is done by these students are able to get the final result of a mathematical problem. It can be shown in the results of the students' answers on point 7 which will be presented in the figure below.



$K = 2 (p + \ell)$
⑦ $K = 2 (22 m + 11 m)$
$K = 2 \cdot 33 m$
$K = 66 m$
$L = p \times \ell$
⑦ $L = 16 \times 6$
$L = 96 cm^2$

Figure 7. Subject Acquiring Solutions

Seventh stage is done by these students are able to write the conclusion of a given mathematical problem. It can be shown in the results of the students' answers in point 8 which will be presented in the figure below.

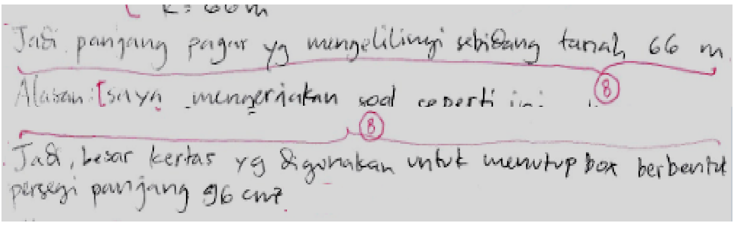


Figure 8. Writing Conclusion

Eighth stage is done by these students are able to write down the reasons of the strategy to get students of mathematics problems. It can be shown in the results of the students' answers on point 9 which will be presented in the figure below.

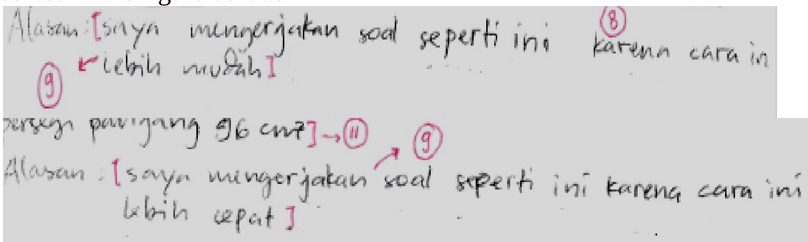

Figure 9. Writing Reasons On Strategies Used

Ninth stage is done by these students are able to write down the reasons about conclusions that students get from mathematical problems. It can be shown in the results of the students' answers on point 10 which will be presented in the figure below.

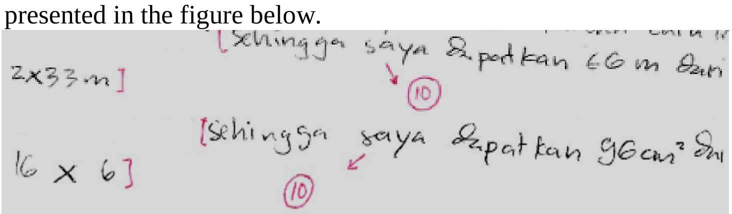

Figure 10. Reasons Writing On Conclusion

Tenth stage is done by these students are able to check the answer back so that no one counted on the job. This is indicated by the results of the interview are presented in the figure below.

Peneliti	:	Berarti kalau misalnya lebih cepat itu apa jawaban kamu sudah benar?
Subjek	:	Eee.. sudah mbak
Peneliti	:	Kok kamu sudah yakin itu dari mana?
Subjek	:	Soalnya tadi sudah diteliti
Peneliti	:	Apanya yang diteliti?
Subjek	:	Eee.. jawabannya
Peneliti	:	Jawaban? Terus gimana jawaban kamu? Sudah benar?
Subjek	:	Benar
Penelliti	:	Yakin?
Subjek	:	Yakin
Peneliti	:	Oke, kalau seperti itu berarti kamu sudah yakin sama jawaban kamu ya?
Subjek	:	Ya yakin
Peneliti	:	Kenapa kok yakin?
Subjek	:	Soalnya sudah diteliti
Peneliti	:	Apanya yang diteliti?
Subjek	:	Jawabannya
Peneliti	:	Terus jawabannya gimana? Gimana dek?
Subjek	:	Benar
Peneliti	:	Benar dari? Sudah yakin benar?
Subjek	:	Sudah

Figure 11. Subject Check Solution Back

The interview above indicates that the subject has been check solution back. Subject believe the answer is correct.

From the above it can be concluded that the reasoning adaptive performed students in solving mathematical problems are (a) to formulate what is known of the mathematical problem given, (b) determining the unknown, (c) formulate the terms in question, (d) find strategies for solving mathematical problems, (e) be able to write formulas to help solve mathematical problems given, (f) found the final result of a mathematical problem, (g) write the conclusion of a mathematical problem, (h) to write the reasons of the strategy being obtained, (i) describes the reasons for their conclusion, (j) checking back solution. Based on the conclusions from these results, it can be done further research associated with adaptive reasoning process of the students in solving mathematical problems.

ACKNOWLEDGMENT

A big thank you goes to the author of the Muhammadiyah University of Purworejo which provides an opportunity to conduct this research. Thanks the author goes to the junior high scholl 4 Purworejo who has given permission to conduct this study.

Active Learning Optimization to Improve Students Critical and Creative Mathematical Thinking

Tri Rahmah Silviani[1], Atik Lutfi Ulin Ni'mah[2]
[1 2](Magister of Mathematics Education, Yogyakarta State University)
rahmahtri9@gmail.com

***Abstract*—**The purpose of this paper is to describe how mathematics educators to face of ASEAN Economic Community (AEC) by optimizing active learning to improve students critical and creative mathematical thinking. Human resources should be formed in this era is that having a competitive mental. Education is one of solution to developing knowledge and skills so as to create the character of a good human resources. In essence, learning is not transfer of knowledge activity but a process of interaction between the students and his environment. Learning paradigm in the 21st century refers to active learning, where educators as facilitators. Usually, traditional teaching is concentrated to lower order thinking skills (recall and basic). Improve critical and creative thinking skills of student is the focus in mathematics education since critical and creative thinking skills is the higher order thinking skills. Kinds of active learning methods: (1) Individual exercises, like the one minute paper, daily journal, reading quiz; (2) Socrates Method, like quiz/test questions; (3) The direct input, like finger signal, flash cards, quotations; (4) Motivator critical thinking; like the pre-theoretical institutions quiz, puzzles/paradoxes; (5) Collaborations, like discussions, note comparison, evaluation of another students work; (6) Cooperative learning, like cooperative group in class, active review sessions, work at the blackboard, concept mapping, visual list, jigsaw group project, role playing, panel discussions, debate, games.

Keywords: *active learning, critical mathematical thinking, creative mathematical thinking*

I. INTRODUCTION

Education is a determinant of the development and progress of a nation. In general, the purpose of education is providing a usable environment allows students to develop the potential and ability to optimally so that they can work for themselves, society and nation [1]. Lickona [2] suggest that the basic fundamental purpose of education according to Socrates is able to form human being smart and better, is aligned with that of education in Indonesia is aimed at educating the nation. The main focus in establishing the knowledge and skills of human resources of this nation that is by education. According to the UNDP report, the value of Human development index, Indonesia in 2014 amounted to 0.684 rated 111 of 188 countries while in ASEAN under Singapore, Brunei, Malaysia and Thailand.

Mathematics is a lesson that did not evolve naturally on students because mathematics is an abstract, rigor and coherence. Mathematics will be understood by student if the educator uses in learning the proper way. Referring to the constructivist learning theory, mathematics studied cooperatively and educators as facilitators. A student will not be able to understand the math if students allowed to find out their own without help of the teacher so that students need scaffolding in learning mathematics. Mathematics has many roles in life, therefore educators should establish that students who have creative and critical thinking skills in studying mathematics.

In the face of free trade and competition as well as the face of the times in the 21's era, there are four skills to be developed by educators to students by National Education Association are critical thinking, communication, collaboration and creative thinking. With attention to low Indonesia's human development index necessary to do an investigation of Indonesian education, especially in mathematics learning. According to survey results Trend in International Mathematics and Science Study (TIMSS), Indonesia began in 1999 in the position of 34 from 48 countries, in 2003 in the position of 35 from 46 countries, in 2007 in the position of 36 from 49 countries and in 2011 in the position of 36 from 40 countries. While according to a survey from Program for International Student Assessment (PISA), studies committed from 2000 position Indonesia of 39 from41 countries, in 2003 in the position of 38 from 40 countries, in 2006in the position of 50 from 57 countries, in 2009 in the position of 61 from 65 countries and in 2012 in the position of 64 from 65 countries [3]. Based on these survey results it appears that Indonesia mathematics achievement in the world cannot be proud.

Education studies has done by the government of Indonesia on the curriculum changes from 2004 that is competency-based curriculum, curriculum 2006 that Education Unit Level Curriculum and national curriculum in 2013 that its use is still not evenly distributed in Indonesia. This is caused by the pros and cons from the education unit. The curriculum applied reflected the education in the 21st century. However, on the ground of learning, educators have not been fully implemented as expected by the learning curriculum. There are still some educators who still use traditional learning in mathematics learning. In traditional learning to the student memorization of understanding so that not returning critical and creative thinking students in mathematics learning. Bransford in Sukarno [4] stated that the most fundamental problem is the traditional education failed to produce the ability to solve problems in life. Because traditional learning only gives simplified and decontextualized problems and not relevant to daily life. While the expectation is that the learning of mathematics education can be implemented in daily life so that mathematics is not considered as an abstract science.

Of the problems that exist in the Indonesian education system are methodologically then there are several ways needed to be done. One strategy that has been, is and will be applied is active learning. Active learning can develop and increase critical and creative learning. Critical and creative learning are higher order thinking skills (HOTS). Minister Regulation the Republic of Indonesia 22 of 2006 of the content standards stated that Mathematics is given to all students to equip them with the ability to think logically, analytical, systematic, critical, and creative, as well as the ability to cooperate. The purpose of this paper is to describe how mathematics educators to face of AEC by optimizing active learning to improve students critical and creative mathematical thinking and this paper is expected to be used as consideration in choosing a model of learning that human resources can be compete in the era, especially for educators who want to grow and develop aspects of students critical and creative mathematical thinking.

II. ACTIVE LEARNING

Learning is something that happens as a result or consequence of experience and precede changes in behavior [5]. Then learning can be defined as the process of abstracting past experience with knowledge gained is now forming a new knowledge that will change the behavior of a depressed individuals. While learning is a process of creating conditions conducive for teaching and learning communication interactions occur between educators, students, and other learning components to achieve the learning objectives. Active learning essentially been there since the time of Socrates, but in fact active learning developing new else in the 21st century.

Active learning is one alternative in cultivate students' critical and creative thinking. Which comes from learning and creative. What is meant here is the interaction of learning and learning communication between educators, students, and other learning components to achieve the learning objectives. While that is activities engagement students in the learning process. So we can say active learning is a model / strategy in learning activities by using the full potential of students optimally, with the aim that they can achieve satisfactory results or objectives according to the personality characteristics possessed by the student [6]. Active learning is very important according to the statement proposed by Silbermen [7] in his book, that "More than 2400 years ago Confucius stated: what I hear I forget, what I see I remember and what I do I understand. From this statement it can be said that active learning can provide a deeper understanding to students compared to learning that is not active as teacher-centered learning or traditional learning.

According to Meyers and Jones that “active learning derives from two basic assumptions: (1) learning its by its very nature an active process and (2) that different people learn in different ways.” Meanwhile, according to Simons that active learning has two dimensions, independent learning and active working [8]. From the opinion of experts, it can be concluded that active learning is learning in which students work active in collecting information learning so that educators as facilitators of learning, in active learning, we will not find another lecture for the students to dominate the classroom than educators, educator only duty deploying the learning process. Implement thinking skills and learning to the level of control of new knowledge and skills effectively are essential for students in active learning. In the active learning is expected to involve high-level skills such as creative and critical thinking are not just memorize, know or understand but also apply, analyze, evaluate and create. In active learning, there are three important goals that need to be fulfilled by educators at the beginning of learning: (1) building a team, aims to have the leaners are able to know each other between each other and will influence the creation of a spirit of cooperation and interdependence among participants students (2) the assertion, in terms of educators will be able to learn the attitudes, knowledge, and experience for the smooth students in the learning process (3) the involvement learn immediately, here educators will be able to generate early interest students in learning activities.

There are several methods used in active learning is student-centered learning, self-regulated learning, collaborative learning, learning-to-learn, problem-based learning (PBL), project-based learning, inquiry-based learning. Some of these methods has a characteristic, advantages and weakness of each. According to Paulson and Faust there are several options of active learning which is based on things related to the learning context [4]:

1. Individual Exercise like (1) The "One Minute Paper"; (2) The Muddiest (or Clearest) Point; (3) Effective Responses; (4) Daily Journal; (5) Reading Quiz; (6) Clarification Pauses; (7) Response to Demonstration or other teacher-centered activity
2. Direct input, like (1) Finger Signals; (2) Flash Cards; (3) Quotations
3. Mate, like (1) discussion; (2) Note Comparison/Taking; (3) Evaluation of Another Students Work
4. Question and answer like (2) Wait Time; (2) Peer Summary; (3) The Fish Bowl; (4) Quiz/Test Questions
5. Motivator Critical Thinking like (1) The Pre-Theoretic Institutions Quiz; (2) Puzzles/Paradoxes
6. Exercise Cooperative Learning like (1) Cooperative Groups in Class; (2) Active Review Sessions; (3) Work at the Blackboard; (4) Concept Mapping; (5) Visual Lists Jigsaw; (6) Group Project; (7) Role Playing; (8) Panel; (9) Discussions; (10) Debates; (11) Games.

III. STUDENTS CRITICAL AND CREATIVE MATHEMATICAL THINKING

Thinking is one of the activities that occur in human life continue. One example of thinking activities is when someone tries to find ways solve a problem. For example, Ani and three of her friend had a rectangular shaped cake, they want the cake is divided into four equal parts.

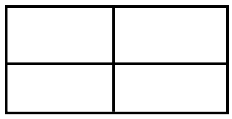

FIGURE 1

When they cut the cake they think is there any other way?

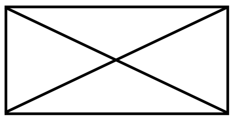

FIGURE 2

Or, what if?

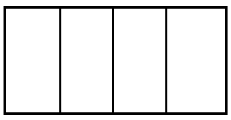

FIGURE 3

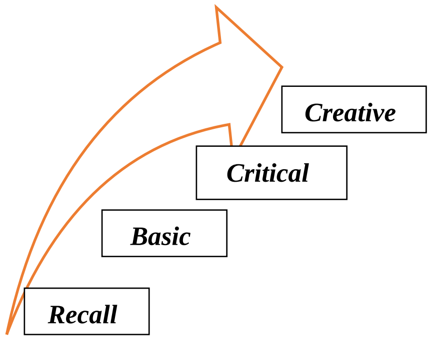
From these example it can be concluded that thinking is a mental activity that involves the brain's performance to an information that can lead to the development of an idea or concept.

There are some education experts argued about the meaning of thinking. Gestalt said that the thinking process cannot be observed using human sensory organs and thinking is a psychic activeness are abstract [9]. While Ruggiero stated that thinking is a mental activity in helping to solve problems, make decisions or satisfy curiosity. Based on the expert opinion that thinking is abstract mental activity in order to find solutions to a problem [10]. In general, that there are two levels of thinking, LOTS (Lower Order Thinking Skills) and HOTS (Higher Order Thinking Skills). LOTS a recall and basic while HOTS is a critical and creative. HOTS is expected ability in mathematics because it can form human resources have the critical and creative thinking skills. critical and creative thinking skills are skills needed in this era.



A. Critical Thinking

Critical thinking is one indicator of HOTS. There are some experts who express opinions about critical thinking skills, one of is Edward Glaser. Critical thinking by Edward Glaser in Fisher are: (1) An attitude would think deeply about issues and things that are within the reach of one's experience; (2) Knowledge of the methods of inspection and logical reasoning; (3) A kind of a skill to apply these methods [11]. Ennis in Feldman argues that critical thinking is the ability to give a reason and reflective focused on what is believed and done [12]. It can be said that critical thinking is analytical and reflective in check, connect, collect, organize, memorize, analyze information and evaluate a problem or situation then this could mean is able to draw conclusions from the data given and are able to determine inconsistencies and contradictions in the group data. If a student is able to think about what if in answer to non-routine math problems that young people have the critical thinking skills.

According to Glaser, while the foundation of critical thinking skills including the ability to [11]: (1) Know the problem; (2) Finding ways that can be used to address these problems; (3) Collect and collate the necessary information; (4) Know the assumptions and values that are not otherwise; (5) Understand and use appropriate language, clear and distinctive; (6) Analyze the data; (7) Assess the facts and evaluate statements; (8) Know the relationship between problems; (9) Appealing conclusions and similarities necessary; (10) Test the commonalities and the conclusions that someone grab; (11) Reconstitute the patterns of a person's belief is based on a broader experience; (12) Make an accurate assessment of things and certain qualities in everyday life.

Moreover, there are examples of some critical thinking styles are:

Explorer	See all sides of a situation or problem Identify the core elements of a problem or situation Want to know Looking for new development
Students	Intelligent Researching other solutions to a problem Doing task Correcting errors
Warrior	Accepting the challenge Persevering

	Faced with a difficult problem
Cicerone	Guiding others Looking ahead Planning a series of actions
Detective	Questioning the thoughts and actions tolerating uncertainty Pursuing elements of fact that are not clear

There are four strategies that can increase critical thinking skills, are:

1) The willingness to look at yourself
   There are several steps that must be done, are:
   a) Ask questions why. In other words, do not accept the things that are seen or heard away.
   b) Identify and resist your bias. Bias can lead to inaccuracies in perception. To eliminate it, we must continue to train our thinking muscles.
   c) Recognize your thought process, and skip unproductive thinking strategies and learn new strategies are effective. That is not affected by the different strategies used by others when they face problems or new challenges. Convince yourself that every person has a different strategy when faced with a problem or challenge.
2) Evaluation of are constantly
   Steps in this strategy, are:
   a) Getting other feeds from other sources. This means did not limit yourself, check or accept a perspective or input from others.
   b) Raised the quality of the existing answers. Each question has an answer that can be judged rightly or wrongly, try to find the best method to achieve a better answer or correct.
3) Constantly are not prejudiced
   Steps for this strategy, are:
   a) Accept other people who might have a different perspective. That is trying to position themselves to be someone else and feel the viewpoint used by the other person. Essentially tries to respect the other person's perspective.
   b) Finding agreement. If there is disagreement, trying to recollect and focus on opposite viewpoints that caused the disagreement.
   c) Recognizing that there are often some solutions to a problem. There is a way out of every problem. So never stop to find various way out of the problems existing.
4) Commitment to the decision taken
   Steps for this strategy, are:
   a) Creating limit of clear analysis. Starting from the basic assumption that obvious and then develop to the stage logical and reasonable.
   b) Get answers to the most credible, rather than waiting for total accuracy be assured that there are still many unknowns in this world, but if we want to try it will not be impossible, all that can be known and refined.
   c) Recognizing the need for agreement or consensus in creating your decision. Account the social context of decisions already taken. Unconscious in ourselves that we live in the real world rather than in cyberspace.

B. Creative Thinking

Hosnan [6] states that the other qualities that necessary developed on the Curriculum 2013 includes creativity, independence, cooperation, solidarity, leadership, empathy, tolerance and life skills of students to form the character as well as the increase of civilization and dignity of life of a nation. According Maite and Laura “Creativity is the capacity to create, to produce new things” [13]. Isaksen declared that creative thinking is a process of forming an idea related to aspects of fluency, flexibility, novelty, and original. While McGregor declared that creative thinking is a process that leads to new knowledge, new ways of know something [14]. Based on expert opinion it can be concluded that creative thinking is a mental activity used by someone to build on the ideas that generate new knowledge. Creative thinking usually caused by problems not ordinary that creative thinking is a process of construction of ideas that lead to the acquisition of new insights or new ways to produce a concept on the existing problems. In mathematics, students' creativity will appear when educators provide a non-routine problem for students. Creative thinking is rational and reflective. The activities carried out such unify ideas, create new ideas, and determine its effectiveness. The results of this thinking skills is something complex. Creative thinking also includes the ability to draw the conclusion that the end result is usually produced the new ones. Students who have high creativity in solving non-routine problems in mathematics will ask himself, Is there another way?

Pehkonen said creativity is not only found in learning the art, science and so on, but can also be found in the learning of mathematics [15]. Krutetskii declared that mathematical creative thinking ability is the ability to get the solution of a mathematical problem is easily and flexibly [14]. It can be concluded that creative thinking ability is the way an individual mathematical construct an idea in solving non-routine problems in mathematics. Characteristics of students who have a creative personality in Munandar by Csikszentmihalyi [1]:

1) The creative individual has the physical energy to fully concentrate on working for hours, and they also can be calm and relaxed depending on the circumstances.
2) Ability to convergent and divergent thinking
3) Having a combination of playfulness and discipline
4) Personal creative can alternately in issuing the imagination and fantasy but still thinking realist.
5) Shows tendency either introversion or extroversion
6) Have an attitude humble and proud of his work at the same time
7) Have a tendency psychological androgyny
8) Tends independently even perverse but could remain conservative and traditional
9) It is passionate when it comes to their work
10) Brush the open and sensitivity often makes him suffer when their work gets a lot of critical.

In general, students who have creative curiosity, interests and passions to get something done. They are more willing to take risks in trying to find something new of a problem. If they still think of a problem is still possible to get an answer in any other ways, then they will try.

IV. Active Learning to Improve Students Critical and Creative Mathematical Thinking

As the country became a member of ASEAN and Indonesia agreed AEC then require workers who have critical and creative thinking skills are able to contribute energy and thoughts for science, culture, technology, and prosperity of the nation. Cicero said that the character of the citizens is the nation's welfare [16]. This statement indicates that the skills and character of human resources shows the character of a nation, the welfare of a nation depends on the character of human resources. Creativity is a matter that can be established anywhere, one is in school. At school, the educator has a greater role in shaping the character of students. Educators can foster creativity, curiosity and motivation for students. Instead, educators can also cripple creativity, curiosity and motivation in students. This is because educators have more opportunities to excite or cripple creativity, curiosity and motivation of students rather than their parents. Educators have a duty to evaluate the work, attitude, and behavior of students.

In essence it must be recognized that educators cannot teach creativity but educators can allow creativity appear, nurture and excite growth. The most important way to encourage intrinsic motivation in school is establish classroom environment that is free of obstacles that can damage students self-motivated. In addition, the best way for educators to develop students’ creativity is to encourage intrinsic motivation. The meaning of intrinsic motivation here is the motivation that comes from within the student. Intrinsic motivation is very influential on the smooth running of the learning process and the results that will be obtained. This intrinsic motivation will grow if the educator can be a model for intrinsic motivation for the child to freely express their interests and personal challenge to solve a problem or complete a task. Moreover, to some extent educators can also teach the skills of creative ways of thinking confront problems creatively, or techniques to come up with original ideas. Educators should give the broadest possible opportunity for students to express their opinions. Let them freely express what they want to submit. Do not limit. Whether right or wrong, leave it alone. Later slowly educator directing or guiding students to gain knowledge and insight into the true Learning from experience that one sometimes it will make students become more remembered [1].

Has been mentioned before that active learning is a model approach that has types such as PBL, PjBL, the inquiry and so on. Based on research that has been done by Hidayat (Lecturer STKIP Siliwangi Bandung) entitled "Meningkatkan kemampuan Berpikir Kritis dan Mahasiswa Kreatif Matematika SMA Melalui Pembelajaran Kooperatif Think-Talk-Write (TTW)", which states the results that the increased ability to think critically and creatively math students whose learning using cooperative learning Think-Talk-Write (TTW) is better than learning to use conventional methods (KONV) is based on the ability students of high, moderate, and less. Increasing students' critical thinking skills of mathematics derived from conventional learning and TTW in terms of the ability of students are high, medium and low. As for the students creative thinking abilities derived from TTW and KONV on aspects of high ability and are in high qualification [17]. Meanwhile, a second study conducted by Ade Rohayati, Jarnawi Afgani Dahlan, Nurjanah students Department of Mathematics Education FPMIPA of Indonesian Education University entitled "Improving the Ability of Thinking Critical, Creative, and Reflective High School Students Through Education Open-Ended" stating the results that the increased abilities creative thinking of students who get teaching problem solving mathematical (Open-Ended) better significantly compared with students who get expository [18]

V. CONCLUTION

Active learning is learning there since the time of Socrates. As stated by John Dewey that learning activities must be active, directly engage students, learner-centered (SCL = Student Centered Learning). There are several methods used in active learning is student-centered learning, self-regulated learning, collaborative learning, learning-to-learn, problem-based learning (PBL), project-based learning, inquiry-based learning. Then should educators in the era now using active learning in teaching because active learning can improve students critical and creative thinking that will be useful in facing era. Some studies have been conducted by education experts. The results of their research are active learning can improve students critical and creative mathematical thinking

Metacognition Students In Problem Solving

Ummu Sholihah
E-mail: ummu2280@yahoo.com

***Abstract*—**Metacognition is the mind's ability to monitor and control itself, in other words, the ability to know about our knowledge. In mathematics education, the importance of the investigation metacognition students during the mathematics activities that are focused on solving mathematics problems. This study describes the student metacognition in problem-solving Linear Equations System with 3 subjects the first semester students are capable of high, medium and low. By using the "think aloud", the results showed that subjects with high ability seemed to perform activities of metacognition at each stage in problem-solving Polya. Students with medium or lower did not do a good metacognition process in the last three stages of the problem-solving based on Polya step.

Keywords: *metacognition, problem solving, polya*

I. INTRODUCTION

The process of thinking in problem solving is an important thing that needs attention, especially teachers to help students to develop the ability to solve problems in the real-world context and in the context of mathematics. In order for this ability can be owned and developed, it needs the support of teachers, including giving students the opportunity to resolve the issue in its own way, as well as helping students to recognize and regulate their own thinking process when solving a mathematics problem. Process realize and organize the students' own thinking, known as metacognition, which includes thinking about how students make the approach to the problem, choose the strategies used to find solutions, and to ask ourselves about the problem (Gartman and Freiberg, 1993).

Metacognition is generally associated with two-dimensional thinking. The first is the awareness of a person about his thinking (self-awareness of cognition). The second is the ability to use awareness to adjust his thinking process (self-regulation of cognition) (Bruning et al., 1995). The second dimension of metacognition that has the properties of interdependence with each other. Woolfolk (1998) explains that metacognition refers to a way to raise awareness about thinking and learning is done. This awareness will materialize when one can start thinking with a plan (planning), monitoring (monitoring) and evaluation (evaluating) and the results of the cognitive activity. For the same thing, Lee and Baylor (2006) states that metacognition is awareness of the activity of cognition; in this case, metacognition relates to how a person aware of his thinking process. According to Flavell (1979), metacognition is defined as "cognition about cognition" or "thinking about thinking." He also explained that students who manage cognitive activities properly, allowing can handle tasks and solve problems well too.

Problem-solving according to Bailey (1989: 116) is a complex activity and a high level of mental processes. Solving the problem is defined as a combination of new ideas that emphasizes reasoning as the basis for combining ideas to problem-solving.

Arends (2007: 41) states that the learning model based problem is the model of learning by learning approach students on issues of authentic and meaningful to students who serve as the foundation for investment and the investigation of students, so that students can construct his own knowledge, foster a higher skill and inquiry, the student's independence, and improve self-confidence. This model is characterized by the use of real-life problems as something and improve critical thinking skills and problem solving, as well as gaining knowledge of important concepts. This learning model prioritizes the learning process where the teacher's task should focus on helping students achieve self-directed skills.

Some research indicates that metacognition plays an important role in solving problems. Research results Chamot et al. (1992) showed that students were able to absorb the lessons of mathematics at the highest level and obtain information about an exercise in strategy. metacognitive (ie planning, monitoring, and evaluation of learning itself) have better skills in problem-solving. Panaoura and Philippou (2004) shows a result of research that students who are skilled in knowing and regulate cognition and realizes its ability demonstrated ability to think more strategically in solving problems than those who are not aware of how the system works cognition. McLoughlin research results and Hollingworth (2003) showed that effective problem solving can be obtained by providing opportunities for students to apply metacognitive strategies when solving problems. Obviously, that between metacognition and problem solving has a fairly strong relationship.

Metacognition in this study is an overview of what it is about the students' metacognition which involves awareness and regulation of thinking in terms of planning (planning)thought processes, monitoring (monitoring) thinking process and evaluate (evaluation) process and the results of his thinking when solving mathematics problems by phasing Polya (1973).

The purpose of this study is to describe the student metacognition in problem solving of linear equations systems.

II. METHODOLOGY

This study is exploratory research that describes in depth profile of metacognition students of Department of Mathematics Tadris IAIN Tulungagung in solving mathematics problems. The data in this study are described qualitatively and the results in the form of written words, spoken or description of the subject of further research and analysis. Subjects were students of the first semester of academic year 2015/2016 IAIN Tulungagung do junior high school mathematics

Selection of research subjects with the following criteria: (1) is based on achievement test scores were done, the students are divided into three groups of ability, which is a subject capable of high, medium and low. The subject said highly capable, if obtaining a score of 85-100; subject capable of the medium, if obtaining a score of 65-84; and the subject of their low performance, if it obtained a score of 0-64. and (2) require consideration of whether the subject lecturer elected scored in accordance with the daily class capabilities and can express opinions verbally or in writing.

The data analysis consisted of three stages, namely data reduction, data presentation and interpretation or conclusion. Includes data reduction process to summarize, pick things that are basic, focusing on things that are important, look for themes and patterns. Presentation of data which presents the data is reduced so that the data is organized, arranged in a pattern of relations. Interpretation and conclusion of interpreting the data that has been presented later concluded.

Problem-solving test instruments are as follows

Problem 1: Three chickens large, medium and small weighed. If large and small, weighed 2.6 kg. If large and are being weighed 3 kg. And if that was small and weighed 2 kg. The third heavy chicken it was exclusively ...

Problem 2: Ali, Ani, Budi go to the store to buy pencils and books alike. Ali bought two pencils and two books, Ani buy three pencils and four books, while Budi buys a pencil and two books. If Ali and Ani consecutive pay Rp 2,500, - and Rp 4,500, - then Budi have to pay?.

III. RESULT

The data analysis was done for each phasing Polya (1973), the stage of understanding the problem, the stage of making plans Problem solving, the problem-solving phase of implementing the plan, and the stage to re-examine the results of problem-solving.

At this stage of understanding the problem, the students capable of high, medium or low in the first part, the core part and the latter part of the subject of metacognition activity.Subject matter carefully read and thoroughly showed that all three subjects to give attention to the information received so that information can be understood and remembered. After reading about the test, the three subjects to process the information shown on the response of the subject, which mentions things known and it asked of the matter and state the reasons underlying the answer. The process of calling back the information indicated by stating that the problem is a system of linear equations. Then the subject is also aware of the process and the results of monitoring the implementation of the current thinking in understanding the problem. This is indicated by the subject to think about prior knowledge is required, as well as proof of steps to be implemented even had planned to use the method to be used and has to think about the consequences of the choice of method to be used. In addition, subjects are aware of the process and the results of his thinking, in evaluating the measures, while understanding the problem. This is indicated by the subject to think about the choice of notation used and also think about the sufficient conditions that will be used for completion has been considered sufficient even the expected time to solve the problem is quite rational.

At this stage of thinking about plans problem solving, students are highly capable conscious in planning to say that after reading about the first thought is to imagine the use of elimination and substitution because you know: is the problem of linear equations 2 variables, but the student capable of analysis was low is still experiencing difficulties in determining the most appropriate way to resolve the matter. Subject highly capable aware of the process and results of thinking in developing the plan when thinking about a plan of action. It was shown at this stage subject to mention that in a short time has been able to plan a settlement, even related notions have been acquired and confident with what was planned. Then the subjects are aware of the process and the results of his thinking, in monitoring the implementation of the current thinking of a plan of action, as shown by the subject to remember that there are similarities with the problem earlier settlement ever doing that is a problem system of linear equations.

At this stage of implementing the action plan by selecting the completion strategy, highly capable students in the first part, the core part and the latter part of the subject of metacognition activity are good, but the student is not capable of being dang low. Subject highly capable aware of the process and results of thinking in developing the planning when implementing the action plan. This is indicated by the subject can easily solve the problem by using concepts, formulas or mathematics operations that have been previously understood, even a little suspicious with the smooth settlement can be a sign there is an error. Then the subjects are aware of the process and in monitoring the implementation of the results of his thinking at the time of carrying out a plan of action, this matter can be shown by the subject in detail explaining each step made. Likewise, the subject is also aware of the process and the results of his thinking in evaluating the action when implementing the action plan, which is indicated by the subject says confident 90% steps taken correctly, even feel no need to replace the measures taken, even the subject is also aware that there are steps unnecessary.

At the stage of evaluating and re-examine how best solution, highly capable students in the first part, the core part and the latter part of the subject of metacognition activity is good, but the student capable of analysis of medium and low no. Subject highly capable aware of the process and results of thinking in developing the plan at the time of evaluation. This is evident from his actions do check each step and looking back the answer. Then the subject is also aware of the process and the results of his thinking, in monitoring the implementation of the current evaluation. Subject unknowingly conducting well, even feel the answer is satisfactory and felt confident of being able to apply this method to other problems and although it has not had time to think of different ways, but be aware that the settlement is done is right. Likewise, the subject aware of the process and the results of his thinking in evaluating the action when performing evaluations. The subject was not necessary to the beginning because it is convinced the answer is correct.

IV. CONCLUTION

This study resulted in that at the stage of understanding the problem, the students capable of high, medium or low in the first part, the core part and the latter part of the subject of metacognition activity. Students with high ability seemed to perform activities at each stage of metacognition in problem-solving Polya. Students are capable of being, or lower did not do a good metacognition process in the last three stages of the settlement of the problem based on Polya step. Students with the moderate and low level of capability only look do metacognition at the stage of understanding the problem.

Finally, suggestions can be submitted in this research is student should always train in solving mathematics problems. In each stage of completion, the step should be trained metacognition process. The results could be used as one ingredient information to make more extensive research on metacognition students in solving mathematics problems with different characteristics and materials.

Developing Mathematics Learning Material Based On CTL For Senior High School

Topic: Series and Sequence

Venti Indiani[1], Dyah Purboningsih[2]
[1] Postgraduate of Mathematics Education, Yogyakarta State University
Indonesia
[2] Postgraduate of Mathematics Education, Yogyakarta State University
Indonesia

***Abstract*—** This research aims to produce mathematics learning material that consists of lesson plan and students worksheet based on Contextual Teaching and Learning (CTL) for grade X Senior High School and to describes the quality of the learning material that has been developed based on validity, practicability, and effectiveness aspects. The research type is development research with ADDIE model that consists of Analysis, Design, Development, Implementation, and Evaluation. The instruments that used in this research are assessment sheet of lesson plan, assessment sheet of student worksheet, student response questionnaire, and student achievement test. The results of this research are a lesson plan that used for three times learning process and a students worksheet with CTL approach on series and sequence for grade X Senior High School. In addition, based on the assessment of material expert, media expert, and mathematics teacher, the result of the research shows that learning material developed is very valid reviewed from lesson plan with an average score of 4.40 from maximal score 5 and student worksheet with an average score of 4.65 from maximal score 5. Based on the result of the student questionnaire responses, the learning material developed is very practical with an average score of 4.22 with maximal score 5. Meanwhile based on the students achievement test, the learning material is very effective used in learning activities as 83% of students who mastery the material.

Keywords: *learning material, CTL, series and sequence.*

I. INTRODUCTION

One of the specific objectives of learning mathematics in high school is that the learners (students) have a broad view and have respect for the usefulness of mathematics, critical thinking, logical, objective, creative, and innovative [1]. One of the efforts to achieve these goals is through the improvement of the curriculum. Today, Indonesia has been implemented Curriculum 2013.

Based on Permendikbud 2013 [2] about Basic Framework and Curriculum Structure SMA/ MA, mathematics in high school get into groups of mathematics compulsory and mathematics specialization. Group of compulsory subjects are part of general education is education for all citizens of the nation aims to provide knowledge, attitude as a nation, and the important ability to develop personal lives of learners, community, and nation. Meanwhile a group of subjects of specialization aims to provide opportunities for learners to develop an interest in a group of subjects according to the scientific interest in the college, and to develop their interest in a discipline or a particular skill.

According to the curriculum in 2013, has been set in Permendikbud 2014 [3] about Learning in Elementary Education and Secondary Education, which is to achieve quality learning, learning needs to implement several principles, namely: (1) students are facilitated to find out, (2) students learn from a variety of learning resources, (3) the process of learning to use a scientific approach, (4) competency-based learning, (5) integrated learning, (6) learning that emphasizes the divergent answers that have multi-dimensional truth, (7) learning based skills applicable, (8) an increase in the balance, continuity, and the relationship between the hard-skills and soft skills, (9) learning that promotes and empowering learners acculturation as a lifelong learner, (10) learning to apply the values to give exemplary (*ing ngarso sung tulodo*), build willingness (*ing madyo mangun karso*), and develop the creativity of learners in the learning process (*tut wuri handayani*), (11) learning that takes place at home, at school, and in the community, (12) use of information and communication technologies to improve the efficiency and effectiveness of learning, (13) the recognition of individual differences and cultural background of learners, and (14) fun and challenging learning environment. In addition, during the learning process, the learners are encouraged to find their own and transform complex information, check the new information with old information that already exists in memory, and developed them into new information or capabilities that suit with the environment and the time and place of their life.

Based on the above it can be seen that the learning of mathematics in high school based Curriculum 2013 not only aims to make the students understand and master the concepts, but also the learners able to apply these concepts into daily life problems.

Meanwhile based Permendikbud 2013 [4] concerning the standard of primary and secondary education, the learning plan need for learning material which includes the preparation of lesson plan and media and learning resources, assessment sheet, and learning scenarios. Lesson plan is arrangement of face-to-face learning activities for one or more meetings. Lesson plan was developed from the syllabus to guide the learning activities to achieve the Basic Competency (KD). One of the components that should exist in the lesson plan is a source of learning. This source of study can use books, print and electronic media, students worksheet, the environment, or other relevant learning resources. Thus to obtain the relevant learning resources, teachers are expected to develop teaching materials as a source of learning.

According to the observations in SMAN 1 Muntilan Magelang Regency and interviews with mathematics teachers, it is known that the learning activities undertaken lasted quite well, but learning resources used are still fixated on printed books provided by the Ministry of Education and Culture (Kemendikbud). In the learning process a lot of students are still using the old curriculum book presents only an instant formula without providing an opportunity for learners to construct their own understanding of a concept. This causes learners difficult to apply the concepts that they have learned in everyday life problems. During the learning activities take place many of the students who asked about the usefulness of mathematics in everyday life. Therefore, it is necessary to develop a learning material that can assist learners in linking the materials studied with the existing problems in daily life.

Nowadays, the role of the teacher in the learning process is no longer as a conduit of information, but as a facilitator for learners in learning activities. In learning mathematics, teachers should provide opportunity for learners to be actively involved so that the concept of the material being studied completely embedded and they know well. Learning mathematics will also be more meaningful if the learners are able to relate what they learn to the problems in daily life (Johnson) [5].

That is the background of the author to develop learning material such as lesson plans and students worksheet that can facilitate learners to construct their own knowledge. Based on interviews with mathematics teacher from SMAN 1 Muntilan Magelang Regency, learners are still difficulties in learning the material sequence and series. Therefore, the authors chose the material sequence and series to be poured into the students worksheets that will be developed with Contextual Teaching and Learning (CTL) approach.

The learning material with CTL approach can motivate learners to understand the material they learned by linking that material with the context of learner‘s daily life. Through CTL approach students not only memorizing formulas but also doing the understanding activity so that they can link the material with daily life problem.

According to Ditjen Dikdasmen [6] learning with CTL approach will help learners to construct their knowledge (constructivism), encourages learners to ask (questioning), facilitating learners to find the concept (inquiry), creating a learning community through discussion groups (learning community), presents a model in the process of learning (modeling), to assess the authentic assessment (authentic assessment), and habituate learners in the reflection of a sequence of learning activities that have been carried out (reflection). CTL approach not only helps learners to be able to relate what he had learned with everyday life, but also CTL approach helps learners to construct their own knowledge through discussion groups.

Development research of learning material with contextual approach had been done previously by Yudha Prihadi [7]. The results of the study entitled "Development of Mathematics Learning Material with Contextual Approach on Trigonometry for High School Grade X" indicates that the response of students towards learning mathematics with contextual approach included in the practical classification. It is shown the average total score of 80.73 with a maximum score of 100. The students worksheet is also effective to use in terms of the results of the learning achievement of students who achieve mastery percentage of 90% or satisfied the criteria very effective.

Based on problem above, the author considers the need for a development of learning material that consist of lesson plan and students worksheet with CTL approach on sequences and series to support learning activities. This development research entitled "Developing Learning Material with Contextual Teaching and Learning (CTL) Approach on Sequences and Series for High School Grade X".

The purpose of this study is to develop a mathematics learning material using CTL approach on sequence and series for Senior High School Grade X according to Curriculum of 2013. Good learning material satisfy validity criteria, practically criteria, and effectiveness criteria (Nieveen) [8]. The validity criteria ware based on the feasibility of the content, language, presentation, and graphics that defined in Permendikbud 2013 [9].

II. RESEARCH METHOD

This research was an development research to produce a mathematics learning material that consist of lesson plan and students worksheet. The research was carried out from 17 to 28 November 2014 in X IPA 2 SMAN 1 Muntilan Magelang Regency. The subject of this research was the students of X MIA 2 SMAN 1 Muntilan Magelang Regency 2014/2015.

The research procedures of this research was adapted development procedures of ADDIE model namely analysis, design, development, implementation, and evaluation (Wina Sanjaya) [10]. Analysis stage consisting need analysis, curriculum analysis, and learner analysis. Design stage consisting preliminary design of learning material (lesson plan and students worksheet) and validation of the assessment instruments of the product by expert lecturers. Development stage consisting product validation by a lecturer as a subject matter expert, a lecturer as a media expert, and mathematics teacher that the results will be used as a reference in revised the product. After the product was stated feasible to use, then product were tested in school. In addition, at the end of the product testing, students were asked to fill student responses questionnaire and do students achievement test. All the data that had been collected were analyzed by researcher. The last stage was evaluation. In this stage, researcher did the revision of learning material.

In this research, there were qualitative and quantitative data. Qualitative data consists of the comment and recommendation of validation by contain expert, media expert, and mathematics teacher. Quntitative data consists of the result of learning material validation, students responses questionnaire, and students achievement test.

Assessment sheet of the lesson plan arranged by several aspects such as identity, time alocation, indicators and learning objectives, learning material, learning approach, learning resourches, learning activity, and assessment. Assessment sheet of student worksheet arranged by the feasibility of contain, presentation, language, and graphics.

The instruments used in this research were assessment sheet of the lesson plan and assessment sheet of student worksheet to assess the validity, students responses questionnaires to assess the practically, and student achievement test to assess effectiveness.

The assessment sheets were given to material matter expert, media expert, and mathematics teacher. This assessment sheet and the student responses questionnaire were in the form of rating scale by five categories of assessment. The student achievement tests were designed based on the basic competencies and indicators that have been determined.

The data from this research was collected by observation, responses questionnaires, and test method. Responses questionnaires consists of assessment sheet of the learning material, students responses questionnaires.

The validity and practically of the developed product can be analyzed by several steps such as data tabulation, calculate the average score, and convert the average score into qualitative criteria based on Table 1 (Eko Putro Widyoko) [11].

Table 1. Conversion of Quantitative Data Into Qualitative Data

Interval score	Criteria
$X > \overline{X\iota} + 1{,}8\ SBi$	Very Good
$\overline{X\iota} + 0{,}6\ SBi < X \le \overline{X\iota} + 1{,}8\ SBi$	Good
$\overline{X\iota} - 0{,}6\ SBi < X \le \overline{X\iota} + 0{,}6\ SBi$	Enough
$\overline{X\iota} - 1{,}8\ SBi < X \le \overline{X\iota} - 0{,}6\ SBi$	Less Good
$X \le \overline{X\iota} - 1{,}8\ SBi$	Very Less

with,

$\overline{X\iota}$ = $\frac{1}{2}$(maximum score+minimum score)

SBi = $\frac{1}{6}$(maximum score-minimum score)

X = Average score

5 = Maximum score

1 = Minimum score

According to Table 1, it can be determined the interval of the assessment of learning material such as:

Table 2. The Interval of Validity Criteria of Lesson Plan and Students Worksheet

No	Score Interval	Category
1	$\bar{X} > 4,2$	Very Valid
2	$3,4 < \bar{X} \leq 4,2$	Valid
3	$2,6 < \bar{X} \leq 3,4$	Enough
4	$1,8 < \bar{X} \leq 2,6$	Less Valid
5	$\bar{X} \leq 1,8$	Very Less Valid

Table 3. The Interval of Practically Criteria of Learning Material

No	Score Interval	Category
1	$\bar{X} > 4,2$	Very Practical
2	$3,4 < \bar{X} \leq 4,2$	Practical
3	$2,6 < \bar{X} \leq 3,4$	Enough
4	$1,8 < \bar{X} \leq 2,6$	Less Practical
5	$\bar{X} \leq 1,8$	Very Less Practical

The learning material developed fulfills the validity and practically if it can achieve the minimum criteria are valid and practical.

To assess the effectiveness of the product developed can be complete by analyzing the outcome of student achievement test. The data can be analyzed by tabulated the results of students achievement test, make a percentage of the students mastery in a test, and then matched with the students mastery categories on the Table 4 (Eko Putro Widyoko) [11].

Table 4. Students Mastery Criteria

Interval	Criteria
$K > 80$	Very Effective
$60 < K \leq 80$	Effective
$40 < K \leq 60$	Enough
$20 < K \leq 40$	Less Effective
$K \leq 20$	Very Less Effective

with,
K= percentage of students mastery the material

The learning material satisfied the effectiveness when the minimum criteria were effective.

III. FINDING AND DISCUSSION

The product developed by ADDIE process in this research was a mathematics learning material consisting of a lesson plan that used for three times learning process and a students worksheet with CTL approach on sequence and series for grade X. Lesson plan was developed based on lesson plan format in Permendikbud 2013 [4]. While student worksheet was developed based on Depdiknas [1]. The quality of the product was assessed from three aspects of validity, practically, and effectiveness.

The validity of the learning material was assessed by the experts and mathematics teacher. The validity result of lesson plan was shown in Table 5.

Table 5. Validity Result of Lesson Plan

Aspect	Average	Criteria
Identity	4.67	Very Valid
Identity Compehensiveness	4.67	Very Valid
Time Allocation	4.33	Very Valid

Clarity learning objectives with KD	4.44	Very Valid
Compliance with the purpose of learning	4.33	Very Valid
Compliance with the learner's capabilities and needs	4.17	Valid
Suitability of the approach and methods of learning with the learning objectives	4.33	Very Valid
Suitability of the approach and methods of teaching to learners characteristics	4.33	Very Valid
Compliance with the standards process	4.49	Very Valid
Suitability of learning resources to the learning objectives and learner's characteristics	4.33	Very Valid
Conformity assessment techniques with the learning objective	4.33	Very Valid
Existence and clarity of assessment procedures	4.5	Very Valid
Average	4.40	Very Valid

According to the Table 5, it was given that the lesson plan reached the minimum criteria of valid in all aspects. Thus, based on the interval of validity criteria of lesson plan in Table 5, known that the lesson plan was resulted in very valid criteria with an average score of 4.40. Based on the result of validity was known that lesson plan that has been developed was appropriate with lesson plan format in Permendikbud 2013 [4].

While the validity result of students worksheet was shown in Table 6.

Table 6. Validity Result of Students Worksheet

Aspect	Average	Criteria
Contain	4.4	Very Valid
Presentation	4.6	Very Valid
Language	4.7	Very Valid
Graphics	4.9	Very Valid
Average	4.65	Very Valid

Based on Table 6, it was given that the student worksheet reached the minimum criteria of valid in all feasibility aspects. Thus, based on the interval of validity criteria of student worksheet in Table 2, known that the student worksheet was resulted in very valid criteria with an average score of 4.65. This indicated that students worksheet reached the feasibility aspect as regulated in Permendikbud [9].

Reviewing from the lesson plan and student worksheet, it can be conclude that mathematics learning material developed was very valid, had a strong theoretical framework, and consistency of relationship between each components.

The practically of mathematics learning material was known from the results of students responses questionnaire as the Table 7.

Table 7. Student Responses Questionnaire Results

Aspect	Average	Criteria
Usable	4.26	Very Practical
Contain Compehensiveness with CTL approach	4.30	Very Practical
Easiness	4.14	Practical
Attractiveness	4.16	Practical
Average	4.22	Very Practical

According to the Table 7, learning material reached the minimum criteria of practically in all aspects. Thus, based on the interval of practivally criteria of learning material in Table 3, known that the learning material was resulted in very practical criteria with an average score of 4.22.

While the effectiveness of learning material was assessed from the results of the students achievement test as shown in the Table 8.

Table 8. Student Achievement Test Results

Number of students	30
Number of mastery students	25
Percentage of mastery students	83%

Students achievement test consists of 5 item questions that have been verified by expert. This achievement test followed by 30 students and they have to finish the test in 90 minutes. According to the result of the test there are 25 students pass the minimal score (KKM). It means that 83% of the students mastery the material. So it can be said that the learning material developed was effective used in learning activities.

IV. CONCLUSION AND RECOMMENDATION

A. Conclusion

Development of mathematics learning materials that contain a lesson plan that used for three times learning process and a students worksheet with CTL approach on sequence and series for grade X was developed based on ADDIE procedure consisting of analysis, design, development, implementation, and evaluation. The quality of the product was assessed from three aspects; validity, practicality, and effectiveness. Based on the assessment of material expert, media expert, and mathematics teacher, the result of the research showed that learning material developed was very valid reviewed from lesson plan with an average score of 4.4 and student worksheet with an average score of 4.65. Based on the result of the student questionnaire responses, the learning material developed was very practical with an average score of 4.22. Based on the students achievement test, the learning material was effective used in learning activities as 83% of students who mastery the material.

B. Recommendation

In this research, the learning material that was developed from the kinds of criteria of validity, practically, and effectiveness reached in minimal good criteria, then it can be used either for students or teachers to support learning activity in sequence and series.

Teachers' Perception Towards ICT in Mathematics Class: A case study in Yogyakarta Secondary Schools

Wahyu Setyaningrum
Yogyakarta State University (UNY)
Wahyu_setyaningrum@uny.ac.id

***Abstract** – Many countries have been integrating ICT in the classroom. Indonesia is heading towards integrating ICT in education. Teachers' perception is an important aspect to support the ICT integration. This paper presents the survey's results to fifty mathematics teachers in twenty Junior High Schools located in the rural area of Yogyakarta province. The survey reveals that most mathematics teachers participated in this study perceive that ICT has important role in mathematics class. They believe that ICT has positive impact on teaching and learning mathematics in the classroom. However, it is hard for some teachers to integrate ICT in the classroom due to a number of reasons such as technical barriers (computers availability, limited internet connection, electricity shortage, limited budget, and curriculum constrains) and human resources limitation (limited technology literacy both teachers and students, low teacher's motivation and little support from head-teacher). In addition, the teachers also point out another restrain that is students' readiness in using ICT for teaching and learning processes. The findings suggest that trainings for teachers in using ICT are needed and further efforts are required to encourage teachers to use ICT in the classroom. Furthermore, students' readiness needs to be assessed in the future research.*

***Keywords:** ICT, mathematics, teachers' perception*

I. INTRODUCTION

Nowadays, technology becomes an important part in daily life. It has been supporting education for a long time through the innovation in technology such as radio, tape-recorder, television, camera, computer, software and internet. Furthermore, it has been change the process of teaching and learning in the classroom, for example, the way teachers teach, the way students learn and the way schools are managed. Kessler [1] argues that ICT can enhance learning process in eight ways: 1) better simulations and models; 2) global learning; 3) virtual manipulatives; 4) probes and sensors; 5) more efficient assessment; 6) storytelling and multimedia; 7) E-books; and 8) epistemic games. The students can get learning materials easily from internet and explore the materials using many kinds of software that provided in the internet. They also can share and discuss the materials with others students. Consequently, teachers are not merely as sources of knowledge, but rather as facilitators and partners of students in learning processes.

The phenomena above also occur in the field of teaching and learning mathematics at schools. Previous research studies have been found that technology has many advantages in teaching and learning mathematics, for example: Burril [2], Ellington [3] and Olive and Makar [4]. In a simple way, technology can help students to deal with long and complicated calculations and complex models or complex problems. In a broader context, technology can change the nature of mathematics taught in the classroom by engaging students in more mathematical activities such as doing experiment, investigation and problem solving activities that can encourage them not only to find the answers but also to ask questions when solving mathematical problems [5, 6].

Indonesian government have been realizing the importance of ICT in education, therefore they suggest in the newest curriculum (curriculum 2013) that ICT should be integrated in teaching and learning processes in the classroom [7]. However, previous research studies that have been conducted in several parts of Indonesia found that there are many obstacles faced by teachers in integrating ICT in education. The common obstacles for teachers in integrating technology in teaching and learning processes in the classroom are lack of knowledge and skills, lack of technical supports, lack of facilities (e.g.: electricity, computer, software and internet access), insufficient incentive or rewards for teachers and insufficient training for teachers [8, 9].

Considering the importance of ICT in education particularly in teaching and learning mathematics, this paper investigates teachers' perception in using ICT in mathematics class. Perception is an important factor in implementing ICT in the classroom [2]. Perceptions could influence the willingness of the teachers in using technology in the classroom [10]. If they perceive ICT negatively, they tend to avoid using technology and vice versa. In addition, there are very limited studies on teachers' perceptions towards ICT that have been conducted in Indonesia. Therefore, this study tries to contribute on this issue by identifying perception of secondary school mathematics teachers in Yogyakarta, one city in Indonesia.

II. LITERATURE REVIEW

A. Teachers' Perceptions towards Integrating ICT in the Classroom

The perceptions of teachers toward using ICT in education system is a very complex phenomenon that includes receiving stimuli and information they get from their environment [11]. This process begins with cognitive process in the form of ideas, concepts and comprehension on the object they observe or they found [12]. Therefore, perception toward a certain object refers to responses towards opinion, ideas or situation that live in the memory and could affect their behavior. Other terms that are often used for a similar purpose with perceptions is views, opinion, and interpretation. This study focus on identifying teachers' perception towards integrating ICT in mathematics class. The perceptions in this study refers to the opinion of the teachers in using ICT in mathematics class. This includes their opinion related to the effectiveness, easiness and usefulness of technology in mathematics class.

The literature on teachers of mathematics has explored their beliefs on teaching and learning, their attitudes toward computers, and the obstacles they perceive in integrating technology. Early literature on this issue indicated that many teachers feared that using technology would harm students' understanding of basic math concepts, make them overly dependent on technology, and not be effective as an instructional tool [13, 14]. In addition, teachers indicated that they had not observed any software that really helped learning and using software did not save time in teaching or evaluation [15].

Literature also identified many factors influence the perceptions of teachers toward technology in teaching and learning processes. Teachers' educational beliefs about teaching and learning, about students, about pedagogy, and about the role of technology are several factors that strongly influence the ICT integration [16, 17]. The integration is not only influenced by internal factors of teachers, but is also influenced by environmental factors. For example, the support from head teachers and other teachers can affect teachers in integrating the ICT in the classroom. The availability of the gadget, curriculum, and support from supervisor and staff are the other factors that influence teachers' perception [18, 19].

In Indonesia, teachers seem to have similar obstacles as mentioned in the previous studies. Marwan [8] conducted a study in university, he found that lack of knowledge and skills, technical supports and incentive are main barriers for teachers in integrating technology in teaching and learning processes in the classroom. Moreover, Sumintono [9], in his study with science teachers, points out similar issues, limited teachers' skills, insufficient technology tools, and insufficient technical staff seems to be the most common problems in integrating technology in the classroom. There is no prior study, to the best known of the researchers, about secondary mathematics teachers' perception on technology usage hence this study aimed to fill this gap.

B. Technology Acceptance Model

There are many tools that have been developed to measure perception of technology usage. The technology acceptance model (TAM) is one of the most widely used models [20]. TAM was developed based on theory of reasoned action by Fishbein and Ajzen's [21]. This model was initially used as to measure user acceptance of computer technology. Several scholars claimed that TAM has good predictive power [22] which makes it easy to apply to different situations [10]. Thus, it is argued that TAM will also be useful in the predicting and explaining technology usage in Indonesia.

Empirical studies provide evidence that this model have high validity [23]. According to TAM, IT behaviors are mainly based on users perceptions of the easiness usefulness of the systems. Therefore, this model consists of two variables: perceived ease of use and perceived usefulness. Perceived ease of use refers to "the degree to which a person believes using a particular system would be free of effort" while perceived usefulness refers to "the degree to which a person believes that using a particular system would enhance his or her job performance" [24, p. 320]. The framework of the technology acceptance model is shown in Fig 1 below.

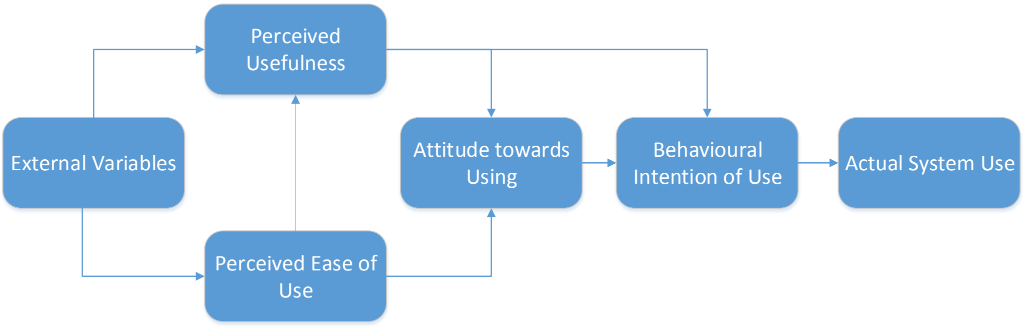

FIGURE 1. Technology Acceptance Model, adapted from [22]

The various studies conducted by researchers have tried to modify the TAM by adding new variables to it. For example, Agarwal and Prasad [25, 26] modified TAM by considering compatibility as a new variable. Moon and Kim [27] has added a new variable playfulness factors to study acceptance of the world wide web. Chau and Hu [28] combined the influence of peers with TAM.

The variables of TAM encompass the definition of perception of this study that mentioned in the previous section. Therefore, it is argued that TAM is an appropriate model for identifying teachers' perception for this study. This study modified the initial items of TAM to measure the perception of integrating ICT in education for mathematics teachers in secondary schools in Indonesia particularly in Yogyakarta. Sample of the measures and the variables are shown in table 1.

TABLE 1. Variabels and Sample Questions

Section	**Sample questions**
Perceived of Ease of Use	1. Using ICT in math class would be easy for me. 2. I would find it is easy to integrate ICT in mathematics class. 3. Using ICT in class requires much time to prepare. 4. Using ICT in mathematics class is confusing for my students. 5. It is difficult for me to use ICT in my mathematics class.
Perceived Usefulness	1. Using ICT allows me to increase my ability to teach mathematical concepts. 2. ICT would help me to illustrate the mathematical concept clearly. 3. Using ICT would enhance my effectiveness in teaching mathematics. 4. Using ICT would make mathematics more interesting for my students. 5. I cannot see any advantages of using ICT in my mathematics class.

III. METTHOD

A. *Participants*

The research particiants are fifty mathematics teachers in twenty Junior High Schools. These schools are located in the rural area of Yogyakarta province. The reasons for choosing schools in the rural areas is that there is limited access to the ICT. Therefore, we want know teachers' perceptions towards integrating ICT in education within that limitation.

The method of choosing the participants is voluntary and random sampling. All secondary mathematics teachers in all rural areas in Yogyakarta were invited to participate however only fifty of them are willing to participate.

B. *Instruments*

This research is a descriptive-qualitative research. The main tool of data collection is the questionnaire that elicits information on the respondents' views of the use of technology on the classroom. The questionnaire is developed based on TAM model, as discussed in the last part of literature review above. Data from questionnaire are enhanced by data gathered from interview with several teachers. Semi-structured interviews were used as the instrument for collecting data. Semi-structured interviews provide the researcher and participants with the opportunities to discuss some topics in considerable detail. In addition, the researcher can use cues or prompts to encourage the interviewee to consider the question further [29]. The questions asked in the interviews were meant to uncover information about teachers' perceptions and their intention to use ICT in mathematics class. It also used to gather obstacles, if any, in integrating ICT in the classroom.

C. Analysis

Data gathered from questionnaire are sorted and organized using SPSS. The data then analyzed descriptively including mean, modus, median of data. On the other hand, data collected from interview are analyzed using thematic analysis approach.

IV. Findings And Discussion

The aims of this study are 1) to determine Indonesian teachers' perceptions of applying technology in the classroom particularly in mathematics class; and 2) to identify the obstacles they may face in implementing technology. Based on these aims, the findings of this study are categorized under two main themes, namely: teachers' perceptions of integrating technology in the classroom and obstacles in applying technology in the classroom.

A. Teachers' Perceptions of Integrating Technology in Mathematics Class

The data of teachers' perceptions are mainly collected through survey questionnaire. The questionnaire consists of two parts. The first part of the questionnaire is aimed to portray demographic information of the participants such as gender, age, grade they teach in, and educational background. The characteristics of the participants are summarized in Table 2 below.

TABEL 2. CHARACTERISTICS OF THE PARTICIPANTS

Categories		#Participants	Percentage
Gender	Male	22	44%
	Female	28	56%
Age	Less than 30 year-old	11	22%
	30-50	36	72%
	More than 50 year-old	3	6%
Grade	VII	15	30%
	VIII	23	46%
	IX	12	24%
Educational Background	Undergraduate	46	92%
	Postgraduate	4	8%

The second part of the questionnaire contains 25 items that modified from the TAM scale. In general, data from the survey show that more than half of the number of participants perceive positively on the integrating of technology in mathematics class. Some of them are stay neutral, they unsure whether ICT would bring any positive or negative contribution in their teaching. Meanwhile, a small number of teachers who believe that the integration of ICT in education is not urgent things to do because they and their students are not ready with the changes yet. The summary of the questionnaire data can be seen in Table 3.

TABLE 3. Data from Questionnaire

Category		Perception		
		Positive	Neutral	Negative
Gender	Male	81.82%	9.09%	9.09%
	Female	53.57%	28.57%	17.86%
Age	Less than 30 years old	90.91%	9.09%	0
	30-50	61.11%	22.22%	16.67%
	More than 50 years old	33.33%	33.33%	33.33%
Grade	VII	80%	13.13%	6.67%
	VIII	69.56%	21.74%	8.70%
	IX	41.67%	25%	33.33%
Educational background	Undergraduate	63.04%	21.74%	15.22%
	Postgraduate	100%	0	0

Taking into account gender differences, data in Table 3 show that most of the male teachers have positive perception of the integration of ICT in education. Meanwhile, only slightly more than half of the female teachers have positive perception, and more than a quarter are neutral. The interviews reveal that those who have positive perception, they believe that ICT would be beneficial for both teachers and students. For example, ICT could provide interactive media and good illustrations so that it would help students in mastering mathematical concepts.

Another interesting data in Table 3 is that teachers who have positive perception are young teachers (less than 30 years old) and those who hold postgraduate degree. The young mathematics teachers claim that ICT has many advantages in teaching and learning mathematics. Similarly, teachers who have postgraduate degree also claim the power of ICT in mathematics class as their main reasons in having positive perceptions.

In relation to the grade, teachers grade VII tend to have more positive perception compare to their counterpart in grade VIII and IX. From the interviews with some grade VIII and IX teachers, they tend to hold negative perception with the integration due to the difficulties in adjusting with the recent curriculum. Grade IX teachers also express their worrying about the integration of ICT that might distract the preparation of the students for national examination.

In summary, the findings have revealed that the majority of participants are aware of the benefits of teaching with technology. They believe that the integration of technology into the classroom can enhance their teaching quality. This can be a good indication of successful implementation of the technology integration program if teachers know about the benefits of technology for teaching and make frequent use of it in their instructional activities [30]. Nevertheless, the teachers also notice several challenges in integrating ICT in education as discussed in the next section below.

B. Obstacles in Applying Technology in the Classroom

The interviews are aimed mainly to identify challenges faced by mathematics teachers in integrating ICT in the classroom. Most of the teachers claim that their technology literacy the main challenges for integrating ICT in mathematics class. They can cope with the rapid development of technology, as represented in the teacher' statement below:

> *Kami itu punya banyak sekali kerjaan, Bu. Ya tentang administrasi seperti membuat rpp, dan juga LKS. Kan sekarang setiap sekolah dituntut untuk membuat LKS sendiri. Jadi kadang tidak ada waktu untuk belajar tentang bagaimana menggunakan alat-alat teknologi yang semakin canggih. Begitu juga dengan software-software mathematika banyak sekali yang baru-baru. Yang lama saja saya belum bias, sekarang ada lagi yang baru. Kadang saya malah bingung dan pusing sendiri hahaha*

From the statement above, teacher argues that he has many administrative matter to do as a teacher and he does not have enough time to follow the technology development. In more specific, he refers to the development of mathematics software, he claims that he has not even finish to learn how to operate one mathematics software yet, but there is more new mathematics software to come. In relation to this, many teachers looking for some assistance from the government to conduct workshops or training for teachers so that they can upgrade their skills in ICT. Moreover, they questioning the technology skills of their students. They claim that many of their students have limited skills, some of them in the rural area even do not have any gadget. Thus, training in technology is an important ingredient in order to integrated technology in the classrooms effectively, as suggested by [31].

Several teachers also mention the technical barriers, for example insufficient number of computers availability at their schools, limited internet connection, electricity shortage, and limited budget. Grade IX teachers also point out that the density of the current curriculum as one of the constrains in using ICT in mathematics class. They argue that they have to deliver so many mathematical concepts in limited length of time, so they worried if the use of ICT would prevent them to finish the material they have to deliver. In addition, the issue of national examination seems to be one of the biggest constrain for mathematics teachers grade IX.

The other challenges found in the interview data are limited human resources who master in ICT to support the integration. In addition, the teachers also mention another restrain that is support from head-teachers. They claim the importance of leader's support. This is in line with the findings of study conducted by Puteh and Vicziany [32]. Diem [33] argues that "teachers who are supported are less likely to feel threatened and develop more positive attitudes toward technology" (p. 495).

V. CONCLUSION

Most of mathematics teachers in this study have positive perception in using ICT in mathematics class. This study also notices that ICT integration in mathematics class face many challenges yet it is possible to do. However, it is important to note at this point that this study involved a small number of teachers in one district. Therefore, the results might not necessarily to represent teachers' perceptions and challenges in technology integration at other part of Indonesia. Some findings may be useful for future research or as a starting point for planning technology integration in schools.

email: warasabondominikus@yahoo.com

Abstract - This paper describes the mathematical knowledges of Adonara society in the marriage tradition known as ethnomathematics. Collecting data were conducted using unstructured interviews and documentation. Interviews were conducted with several informants selected based on the consideration of researcher and suggestion by previous informant. Documentation was done using video recordings and photos. The data were analyzed refers to the characteristics of ethnomathematics that include: *Counting, Locating, Measuring, Play, Designing and Explaining* - CLMPDE. Result shows that there are a number of mathematical knowledges in the marriage tradition in Adonara island called as ethnomathematics such as: counting, measuring, estimating, comparing, sorting, and various geometry concepts. These is found in all process from giving dowry until custom party.

Keywords: *counting, dowry, ethnomathematics, marriage, measuring*

I. INTRODUCTION

One of the students' capitals brought to school is the cultural capital. Teachers should develop learning mathematics based on the student cultural capital to motivate and arouse students' interest in learning mathematics. The use of student' culture as an illustration of concept of mathematics is expected to help students understand the concepts being studied. Exploration charge a mathematical concept in view of culture to foster knowledge and awareness of students that they can contribute to the discoveries of mathematics, because mathematics is not the dominance of a particular culture. Besides, the student culture can be used as context and learning problems in learning the appropriate mathematics concepts. Teachers in teaching mathematics is expected to utilize culture as a context, the media, and also as a learning resources.

But the facts show that the mathematics learning in schools may not use culture as a context of learning. Mathematics learning just focus on textbooks rather than use what was available in the neighborhood including an cultural environment. Cultural environment that involved educational value is not used as a media and learning resources. Teachers are stuck on the notion that learning media and learning resources should be purchased or only from teachers and textbooks. Teachers have difficulty associating specific mathematical concepts with appropriate cultural context. Even teachers are not aware that in the cultural activities contained various mathematical concepts.

Mathematics as a social-culture construction where mathematics is contained in history and in human activity, so it is said that mathematics is a human activity, either already or not yet published ([1] Ernest, 1993, [2] Freudenthal, 2002; [3] Romberg, 2004; [4] Mukhopadhyay and Greer, 2011). It means that the human activities directly or indirectly related to mathematics.

The above description indicates that there are various mathematical knowledge called as ethnomathematics in the marriage tradition in Adonara society. It is based on the fact that the marriage tradition is one of the Adonara community's culture inherited the previous generation and still maintained to the present time. Indepth study was needed to reveal and describe ethnomathematics or mathematical knowledges in the marriage culture of Adonara society and create a mapping concept to show the relationship between ehtnomathematics and school mathematics so that it can become a reference for teachers in developing teaching materials and based-culture learning.

II. LITERATUR REVIEW

A. Mathematics and Culture

Mathematics and culture are related each others. Mathematics on the one hand shaped by culture and mathematics on the other hand is used as a tool for the advancement of culture. In other words, mathematics is not free from the culture but the mathematics as a part of the culture and as a form of human culture.

Mathematics is a socio-cultural construction in which mathematics is contained in history and in human activities. Thus mathematics can not be separated from the humanities and social sciences, or from what is expressed as human culture in general, so it is influenced by the values of humanity as well as other fields of knowledge ([1] Ernest, 1993). Knowingly or not that a lot of human daily activity is always associated with mathematics, so it is said that mathematics is a *human activity,* either already or not yet published ([2] Freudenthal, 2002; [3] Romberg, 2004; [4] Mukhopadhyay and Greer, 2011).

Mathematics as we know is a phenomenon tied to the culture, and every culture has created ideas where clearly labeled as "other mathematics". Also mathematics is a cultural phenomenon, and mathematics as a *pan-human activity* ([5] Bishop, 1988; [6] Dowling, 1998). Furthermore, mathematics (mathematical knowledge) already exists in every culture, embodied in each culture, which, as a " frozen mathematics" ([7] Gerdes, 1997; [6] Dowling, 1998). Mukhopadhyay and Greer defines mathematics embedded in all cultures, much of mathematics as an academic discipline. Raju said that mathematics is a cultural formation, influenced by special philosophy culturally ([4] Mukhopadhyay and Greer (2011). Also Milroy said that all cultures develop their own mathematical forms depending on the needs of their neighborhoods and communities of interest ([8] Milroy, 1992).

Mathematics is a cultural phenomenon, present in every culture, embedded in culture, shaped by every culture, influenced by the culture, and has its own form in accordance with the needs of environmental and community objectives ([9] Dominikus, 2014). This means any different cultures will have different mathematics. In particular it can be said that there is any ***hidden mathematics*** in the Adonara culture while Adonara people never say that they have the mathematics ([10] Dominikus, 2015). In general mathematics in culture is known as ethnomathematics.

B. Ethnomathematics

The meaning of ethnomathematics always change and evolve since it was first introduced by D'Ambrosio in the early 1980s to the present time. The changes associated with cultural significance or cultural groups into ethnomathematics research areas, from ethnomathematics as a research subject heading ethnomathematics as a field of research. It appears in a variety of senses of ethnomathematics as described in this section.

Initially, ethnomathematics related to mathematics practice of illiterate people, and mathematics practice in a culture without written expression of a society which is seen as a primitive society ([11] Ascher, 1997: 26; [12] D'Ambrosio, 1997: xv;). Here Ascher and D'Ambrosio emphasized that the focus ethnomathematics limited to cultural communities that are less or never learned school mathematics.

Further, ethnomathematics referred to a form of mathematics or mathematics contained in the cultural activities of various cultural groups such as ethnic communities, labor groups, children of certain age groups, professional groups, and others ([13] Nunes, 1992; [12] D'Ambrosio, 1997: 16). Milroy (1992) put ethnomathematics deals with the study of different types of mathematics that arise or exist in a variety of cultural groups. Furthermore ethnomathematics relates to a form of cultural knowledge or characteristics of the social activities of a social group or culture, which can be recognized other groups such as west anthropologist , but not necessarily known by the origin, as knowledge of mathematics or mathematical activity ([14] Presmeg, 2007: 440). Mathematical knowledge of a cultural group may be known in the jargon, symbols, myths, and in certain ways people use for calculating, concluding, sorting, and grouping ([15] François, 2012: 1; [16] Meaney, 2008: 52). Previous meanings of ethnomathematics illustrate that ethnomathematics related to mathematics or mathematical practice or mathematical knowledge or mathematical activity in the cultural activities of a particular cultural group. It can be said that we can find a variety of mathematical practice or mathematical knowledge in a certain community groups that can then be said as ethnomathematics.

Currently, ethnomathematics has become the field of research on mathematics in culture ([17] Gerdes, 2014), the relationship between culture and mathematics ([18] Barton, 1996; [19] Alangui, 2006), and the role and influence of ethnomathematics in mathematics and mathematics education ([20] Begg, 2006: 1; [21] D 'Ambrosio, 2001: 1, [22] D 'Ambrosio, 2001: 1; [23] Horsthemke, 2006: 4). In this context, ethnomathematics will enrich mathematics that are commonly known and learned in formal educational institutions during the time and will also affect the mathematics education.

This study describes the practice of mathematics or mathematical knowledge of Adonara society in the marriage tradition. The results of this research can be used as a reference in developing culture-based mathematics learning.

III. RESEARCH METHOD

This research is a qualitative descriptive study with the aim to describe the mathematical knowledge of Adonara society in the marriage tradition. Data were collected with unstructured interview and documentation methods. Interviews were conducted to 5 people custom figure as a subject of study with all aged over 60 years. The data collected related to dowry agreement and its return, giving dowry, and traditional wedding party. Selection of the number of research subjects at the top as well as to ensure the validity of research data. Analysis of data using interactive methods Miles and Huberman which consists of reducing the data, presenting data, and making inferences ([24] Sugiyono, 2007). Data was analyzed descriptively with reference to the characteristics of ethnomathematics comprising: *counting, locating, measuring, play, designing,*and *explaining* ([5] Bishop: 1988).

IV. RESULTS AND DISCUSSION

The marriage for Adonara people be understood not only unite a man and a woman who later became husband and wife, but also unite families on both sides. The mating process consists of a series of rituals associated with the provision of a dowry (bride price) or *welin* and other processes before and after giving dowry. The dowry of Adonara women is ivory together with goats and pigs within a certain amount as a pair of ivory. Replies should be given the woman's family in the form of woven fabric *(kewatek)* and shirts by an amount deemed feasible and commensurate with ivory and how many goats and pigs received.

The highlight of the mating process is to strengthen marriage by a religious institution. In Adonara society the dowry is not an absolute requirement to obtain confirmation of marriage by religious institutions. Giving dowry be implemented before marriage or after marriage in a religious suspended depending on the chosen form of marriage and the agreement of both families. There are several activities that illustrate mathematical knowledges in the marriage tradition as described below.

A. Counting

Counting activities in the marriage tradition found in counting the number of animals as a pair of ivory that would be handed over to the family of the boy female family. It also calculates the number of woven fabrics *(kewatek)* and shirts in reply by the woman's family to the men’s family. Counting Activities also performed to determine the number of animals to be cut and the number of participants plate in custom party. All of these will be described below.

The number of animals as a pair of ivory is usually odd. If the number of animals are 3 that it consists of two goats and one pig. If the number of animals are 7 then at least two pigs and five goats. Usually the number of pigs are less than goats. No matter how many pigs were given to men’s family and women’s family will be cut out for the traditional feast. Otherwise not all goats are cut. Goat called as *bala talin* to be maintained.

When given animal as a pair of ivory is 7 animals consisting of 2 pigs and 5 goats, then in the Lamaholot language expressed as follows, w*awe rua **noon** Witi lema ke ewan **mupune** pito* (2 pigs with five goats so the total animals is 7). It can be written in mathematical sentence as follows: **2 pigs + 5 goats = 7 animals.** In this contex, addition process is done for two subset (pig and goat) from the same set (animal). It shows that concepts of set and subset are hidden within the marriage tradition.

Similarly, in calculating the woven cloth and shirts in retaliation for ivory and animals that have been received. Usually woven fabric *(kewatek)* wrapped in another cloth called *kenabu.* The number of woven fabric *(kewatek)* in each bundle *(kenabu)* between 50-80 pieces. If at the time of the conducting brought 4 packs of woven fabric and 2 packs of shirt then the total is six packs of fabric. In the Lamaholot language spoken in the following, *kewatek kenabu paat **noon** labu kenabu rua **mupune** ale kenabu neme* (4 packs of woven fabric with 2 packs of shirt so altogether there are 6 packs of fabric). The corresponding mathematical sentence can be written as follows, **4 packs of woven fabric + 2 packs of shirt = 6 packs of fabric.** In this contex, addition process is done for two subset (woven fabric and shirt fabric) from the same set (fabric). It shows that concepts of set and subset are hidden within the marriage tradition.

Both of the above illustrates that the addition operation performed by summing the numbers that appear regardless of the attributes associated with that number. It shows that concepts of set and subset are hidden within the marriage tradition. Here counting process or action taken is *pupu* (collect) and the outcome of its actions are *mupune (overall).*

At the time of giving woven fabric and shirts to men's families , if the mother of the girls also come together then when the group back home should be given another three goats. This goat is called *ina umene* or *Witi dese bola'.* If when giving ivory time has brought five goats, then the number of goats were given by men's family entirely 8 tails. In the language of Lamaholot expressed as follows, *Witi lema tali' Witi Telo mu* ***mupune*** *witi Buto* (five goats plus three goats more then totally 8 goats). It can be written in the form of the following mathematical sentence, **5 goats + 3 goats = 8 goats.**

Similarly, if initially brought the number of woven fabric there are 4 packs, but by men's family deemed it is not enough then through good communication between two families, the families of women will add it again. Suppose it is delivered again 2 packs of woven fabric, then the total number is 6 packs of woven fabric. In the language of Lamaholot expressed as follows, *kewatek kenabu Paat* ***tali*** *kenabu rua mu* ***mupune*** *kenabu neme* (four packs of woven plus two packs more so altogether become 6 packs of woven fabric). Corresponding mathematics sentence is, **4 packs of woven fabric + 2 packs of woven fabric = 6 packs of woven fabric.**

The last two mathematics sentences illustrate the process of adding two same set. The addition process is accordance with the usual procedure. In the context of this action to add so-called ***tali*** (add more) and the result of the actions referred to ***mupune*** (overall)). It can be said that in everyday life of Adonara people known 2 activity associated with the arithmetic operation of addition in which the action ***pupu*** and ***tali.*** *Pupu* and ***tali*** actions are often found in other activities of custom party.

The number of animals to be cut firstly discussed by family taking into account the number of animals donated to families of men and the number of woven fabric (*kewatek*) donated to the family of women. Subsequently converted into the number of plate as allotments for each contributor to both animal and *kewatek*. Usually one animal was allotted 15 dishes and one sheet of woven fabric or shirt armor allotted 10 plates. Moreover calculated the number of boy of another family were invited to follow the traditional feast.

After a number of dishes entirely known, discussed hereinafter also how many pieces of meat eligible for each plate. Generally, three pieces of meat on each plate is said to have good *(kererhan me'la),* and more than 3 that is 4 or 5 pieces of it have been the best once *(kerehna mela'-mela ').* With the helping of certain commonly estimated the size of the animal and the amount of meat, then it is certain how many animals will be cut.

Counting the number of animals raised in the family of the boy known that a total of 40 animals (goats and pigs), then the number plate of a total of 600 plates. From the calculation of the boys family are invited to know the number of plate is 150 then the traditional party that there will be 750 dishes. Taking into account the remaining animals for traditional party, it was agreed each dish to share as much as 5 pieces of meat. 1 piece of meat the size of approximately 5 cm x 5 cm x thick meat based meat posture itself (about 3-5 cm). A big pig was estimated to be up for 150 plates, and for a big goat was estimated to be up for 60 plates, then for the traditional feast that will cut the animal at least 7 animals consisting of 4 pigs and 3 goats.

In this process found their arithmetic operations as addition, subtraction, multiplication, and division. The number of dishes that in line with the number of animals can be obtained from the summing 15 as much as 40 times or in the form of multiplication written **40 x 15 = 600.** The total plate in a traditional feast was derived from the number plate in accordance with the number of animals and the number of plate in accordance with the number of boys invited then **600 plates + 150 plates = 750 plates .**

Related to the number of pigs and goats to be cut, it was calculated as follows, 1 pig for 150 plates, then two pigs for 300 plates. If the two times of the pig is 4 then it can be for 600 plates. The rest of the plate is 150 so it can be cut three goats. Here it is understood that the three goats for 180 plates so that it can meet even exceed 150 dishes were leftovers. It can be written as:

1 pigs for 150 plates
2 pigs = (1 + 1) pigs for (150 +150) = 300 plate
4 = (2x2) pigs for (2 x 300) = 600 plate
The rest of the plate = 750-600 = 150
1 goats for 60 plates, then 150-60 - 60 = 30, then the goat could be cut as much as three.

From the mathematical sentence as described above, it is clear that there are some arithmetic operations such as addition, subtraction, multiplication, and division.

B. Measuring

Activities associated with measuring especially the length and the large of ivory. The length of ivory measured by fathoms, while large of ivory measured by the great circle formed by the left and right hand span. Measuring instruments used is not a standard measuring tool but uses a part of the body length and span fathoms.

There are three types of length ivory, those are longer than one fathom, ivory length exactly one fathom, and ivory that is less than one fathom. Here, the unit of measurement is the length of fathoms. The Large of ivory can be classified into three groups, namely the ivory more than one circle formed by the left and right span, the ivory magnitude of exactly one circle formed by left and right span, and the ivory is less than one circle formed by the left and right span. Here, the unit of measurement is the length of the span.

The length of ivory is measured by a spokesman or *pehen koda.* By the length, there are some names of ivory in Lamaholot language as follows.

1. *Bala Raine:* ivory length more than one fathom, (1 fathom = length of the tip of right forefinger to the tip of forefinger of the left hand).
2. *Bala Huut:* ivory length exactly one fathom.
3. *Bala Urat Tukan:* ivory length from the tip of right forefinger into the middle of the palm of left hand.
4. *Bala Beeda' Wua':* ivory-length from the tip of right forefinger into the middle part between the wrist and the middle of the palm of left hand.
5. *Bala Meke Nile / Hayon taa ':* ivory-length from the tip of the forefinger right hand to the left wrist.
6. *Bala Kala U 'lin:* ivory length of the forefinger right hand to the left hand in the right place to have a bracelet or a watch.
7. *Bala Kala keteka:* Ivory length of the forefinger right hand to the left hand is approximately 10 cm from the left elbow to the wrist.
8. *Bala sue lodon:* ivory length of the the forefinger right hand to the left hand approximately 5 cm from the left elbow to the wrist or the left elbow and *kala keteke.*
9. *Bala Leku:* ivory length of the forefinger right hand to the left elbow.
10. *Bala Sue:* ivory length from the tip of the right forefinger to the left arm approximately 10 cm above the left elbow
11. *Bala Soru Nabit:* ivory length from the tip of the right forefinger into the base of the left arm.
12. *Bala Tuho Tukan/korok :* ivory length of the right forefinger to the left breast.
13. *Bala Lega korok:* Ivory length from the tip of the right forefinger to mid-chest.
14. *Bala Lima Papa / kepali papa:* ivory length along one arm.

Based on the large of ivory, it is known that some types of ivory size in Lamaholot language known as:

1. *Higi' telo:* ivory size of one circle formed by the left and right hand span plus three fingers ie index finger, middle finger, and ring finger.
2. *Higi' rua:* ivory size of one circle formed by the left and right hand span plus two fingers, namely the index finger and middle finger.
3. *Higi ' kuluk:* ivory size of one circle formed by the left and right hand span plus index finger.
4. *Suda ':* ivory magnitude of exactly one circle formed by the left and right hand span.
5. *Pesok raru:* ivory magnitude of the circle formed by the thumb and the top segment of the index finger of the left and right hand.
6. *Pesok raru rua:* ivory magnitude of the circle formed by the thumb and middle segment of index finger of the left and right hand.
7. *Darap lema:* ivory magnitude of the width of 5 fingers.
8. *Darap Paat:* ivory magnitude of the width of four fingers.

C. Comparing and Sorting

By measuring the length and large of ivory as described previously, there is comparing activity. The length and the large of ivory are determined according to the name in accordance with the measurement results based on the length of fathoms. In general, the length is divided into three namely ivory that are more than one fathom *(bala raine),* exactly one fathom *(bala huut),* and less than one fathom (ranging from *bala urat tukan to bala kepali papa).*

Likewise with the large and the small ivory is determined in accordance with its name after measured by the great of circle formed by the left and right hand span. In general, the large of ivory is distinguished on 3 ivory namely the large of more than one circle formed by the left and right hand spans *(Higi'),* exactly one circle *(suda'),* and less than one circle *(pesok).*

Another activity that follows the measurement results is the sorting activity. Giving the name of the appropriate length of ivory sequentially ranging from the longest to the shortest ivory or otherwise. Similarly, the naming of ivory corresponding to the large or magnitude in the order from the biggest to the smallest ivory or vice versa.

V. CONCLUTION

From the above description it can be concluded: *first,* although the Adonara do not have any words to mathematics in their lives, but they have a variety of mathematical knowledge used in the whole process of marriage such as counting, measuring, comparing, estimating, and sorting, which refers to the characteristics of ethnomathematics (Bishop: 1988) all of the above is a mathematical knowledge in the mating process, known as **ethnomathematics in the marriage tradition.** *Second,* in the marriage tradition there are also arithmetic operations such as addition, substraction, multiplication, and division. Related to the addition operations there are two action or activity *pupu* (add up of 2 different subsets) and *tali'* (add up of 2 same subsets). *Third*, the used measuring devices are not standard form those are the length of fathoms and hand span. The measurement results such as the length and the large of ivory are not expressed in numbers quantitatively.

Abstraction Measurement of Students in Constructing Proof Algebra Problems

Warli[1], Edy Nurfalah[2]
[1,2] Departemant of Mathematic Education, University of PGRI Ronggolawe Tuban, Indonesia
warli66@gmail.com [1]   eee.edy@gmail.com [2]

Abstract**—**This study aimed to describe the abstraction of measurement of students in constructing the proof of algebra problems. For this purpose, a qualitative explorative research with task-based interview techniques was conducted. The subjects were the students of math education, class of 2013, UNIROW Tuban. Students who became the subject of research has taken a course of Algebra Structure. Measurement of abstraction used RBC models (Recognizing, Building-with, Constructing). Recognizing refers to the fact, the basic concept which has already known. Building-with refers to the combination of facts or concepts into a new context, and Constructing refers to the ability to build a proof of statement/issue based on facts or concepts to show that the statement is true. The main instrument was the researchers themselves, and the supporting instrument was interview guides that referred to the RBC model. Data were analyzed qualitatively. Conclusions were obtained based on the analysis results, those were: Recognizing, students tended to be able to know a few facts, concepts that supported the evidentiary issues, example: the closed nature, associative, neutral element, inverse of element, grupoid, semigrup, group. Building-with, students tended to be able to combine the concept of the closed nature, associative, neutral element, inverse of element, grupoid, semigrup into new contexts that were interrelated. Constructing, students in constructing proof algebra problems, there were still many steps that were illogical in the use of facts or concepts. Consequently, the proof tended to be incorrect, although conclusion was ultimately correct.

Keywords: *abstraction, recognize, building-with, construct, and proof.*

I. INTRODUCTION

Abstraction is a process that is fundamental both in mathematics and mathematics education. Abstraction has been known as something that important role for successful learning of mathematics when viewed from the standpoint of cognitive. However, abstraction is also one of the main reasons of the failure of the process of learning mathematics [1]. Reference [2] the term abstraction is used for both the process and results. To differentiate the two, used the term abstraction process on the one hand, and the entity that generated on the other side. Abstraction is an activity (in the sense of activity theory), a chain of actions undertaken by an individual or a group and driven by a motive that is specific to a context. Abstraction is an activity of vertically recognizing previously constructed mathematics into a new mathematical structure [2].

Abstraction in mathematics is a process for obtaining the essence of mathematics concepts, eliminating dependence on the properties owned by the object and made more general so that it has applied a broader or corresponded with other abstract explanations for similar symptoms. One characteristic of mathematics is to have an abstract object. Abstract concepts in mathematics can be learned through the process of empirical abstraction and through a mathematical abstraction. The abstraction process takes place through a series of learning activities that involve various aspects of learning. Abstraction process is a process of contextualization, because it does not pay attention to the object as well as the characteristics and relationships that are owned. This process is linear, originated from the objects to the class or a structure called the object at a higher stage [2]. Abstract regarded as intrinsic properties of the new object and the importance of context in the process of abstraction.

In broad outline, the abstract can be divided into empirical and theoretical abstraction [3]. In the process of empirical abstraction, the formation of the notion of an abstract object that is based on empirical experience. Both processes are based on the abstractions of social and physical experience of the child. The abstraction empiric focus on the process of identifying important displays are common, then the concepts generated from the empirical abstraction process is also called abstract-general [3]. The idea of the theoretical abstraction stems from two psychologists from the Soviet namely Vygotsky and Davydov. Theoretical abstraction consists of forming concepts to be adjusted to some theories. Vygotsky makes a difference in the meaning of the concept in the context of everyday life with the concept in the context of scientific fields. According to Vygotsky, the concept in the context of everyday life in the form through the process of empiric abstraction. While the formation of scientific concepts consists of three aspects, namely; (a) the establishment of a system of various relationships between concepts, (b) an awareness of the mental activity of a person, and (c) penetration into an essence of the object it will enrich the reality presented in the concept, not vice versa [3].

To perform an abstraction, a person requires logic. Davydov [2] proposes that the origin of events abstraction, namely abstraction starts an initial, simple, undeveloped first form, which need not be internally and externally consistent. The development of abstraction proceeds from analysis, at the initial stage of the abstraction, to synthesis. It ends with a consistent and elaborate final form. It does not lead from concrete to abstract but from an undeveloped to a developed form of the abstract in which new feature of the concrete are emphasized. Reference [4] in processes of abstraction, the epistemic actions are nested. C-actions depend on R- and B-actions; the R- and B-actions are the building blocks of the C-action; at the same time, the C-action is more than the collection of all R- and B-actions that make up the C-action, in the same sense as the whole is more than the sum of its parts. The C-action draws its power from the mathematical connections, which link these building blocks and make them into a single whole unity. It is in this sense that we say that R- and B-actions are constitutive of and nested in the C-action. Similarly, R-actions are nested within B-actions since building-with a previous constructs necessitates recognising this construct, at least implicitly. If the students solve a standard problem, they are likely to recognize and buildwith previously acquired structures. If they solve a non-standard problem, they might get in the process of construction [2].

The problem in mathematics by [5] is divided into two, namely: the problem of determining and evidentiary problems. Further Polya said that "the problem of determining" the more important in basic math, while the "problem of proving" more important in advanced mathematics. Reasoning and thinking logically be authorized to resolve the problem of proof. [5] says that the purpose of proving the problem is to clearly indicate that a statement is true or not. This is to answer the question: is this statement true or false? In line with this, Rav [6] states that the evidence is the way a mathematician to display mathematical tools to solve problems and to justify that the proposed settlement of the problem is the solution. This means that the evidence may help to understand the meaning of the theorem is proved: to see not only the statement is true, but also why it is true.

Reference [7], the ability to prove in mathematics (Algebra Abstract) consists of the ability to construct evidence and the ability to validate the evidence. The ability to construct proof includes the ability to use the methods of proof, definitions, entry, and theorem to demonstrate the truth of a statement in math (Algebra Abstract). While the ability to validate the evidence includes the ability to scrutinize the evidence related to the types proof that often arise in mathematics (Algebra Abstract). Activity validate the proof includes: (1) read a proof in mathematics to determine the truth or a mistake by looking at the suitability of the axioms of the system, the premise, the results of mathematical existing (entry or theorem), with the line of reasoning deductive, (2) completes the proof (if found to be a mistake), (3) compare the 'effectiveness' of the evidence with other proof [7].

From the perspective of cognitive development, [8] explains that the representation of developing proof through four stages, namely: proof enaktif (enactive proof), visual proof (visual proof), proof symbolic (symbolic proof), and proof formal (formal proof). Evidence enaktif, involve a physical demonstration to show the truth; visual proof, involving the creation of graphs or images; symbolic proof, involves manipulating the symbols of algebra; and formal proof involves deductive reasoning. Proof in mathematics has a very important role. These roles are identified by de Villiers [9] such as verification, explanation, systematization, invention, intellectual challenge, and communication. The role of *verification* might be most familiar with the study of mathematics; theorem is not a theorem until it has been verified that it becomes proof construction. The role of the *explanation* is often characterized by the evidence in the classroom. In many classroom context, the purpose is not evidence to show that the theorem is true, but to explain why the theorem is true. Of course, this role is not limited to the classroom. Role of *the invention* may be a little unusual. Historically, the theorem of several areas of mathematics, such as non-Euclidean geometry, are found through pure deductive ways. The role of proof *as communication* is emphasized by the fact that the evidence is written and read by humans, and therefore act as a means of communicating the proof of mathematical results between readers and writers. In addition, evidence can describe a new approach or technique, which may be another mathematician need to equip or prove themselves on different theorems.

Furthermore, how to measure student abstractions in constructing the evidentiary problem? As the *process of abstraction cannot be observed directly* [10], it has been necessary to define observable actions that can give information about the process. In defining the abstraction process, [2] has referred to the major observable epistemic actions as *recognizing*, *building-with* and *construction*, and hence named their model as "RBC". *The RBC Abstraction Model* is based on the activity theory, and comprises three epistemic actions. Some experts there who developed into RBC+C. Hershkowitz, Hadas, Dreyfus, and Schwarz investigate the development of understanding of probability among groups of Grade 8 students in Israel. Using an extended RBC+C model (RBC plus Consolidating), they analyse students' learning in considerable detail and demonstrate convincingly that their model allows the description of theoretical abstraction in terms of epistemic actions. In this study the authors used, RBC models for measuring abstraction students in constructing proof problems.

Recognizing refers to a familiar structure [11]. A previously constructed structure-already used in other situations - is related to this action [12]. Recognizing occurs when the student realizes that the construct that is familiar from a previous activity is connected to or relevant for the mathematical situation in the present activity. It may occur in at least two ways, by analogy and by specialization [10]. In the context proof algebra problems, about the topic in algebraic structures, namely the Group. Recognize the topic group, eg grupoid, semigrup, monoid, and groups. In addition, to get to know about the group, the student must also recognize the closed nature, associative nature, the element of unity / neutral element, inverse of an element, commutative properties. The properties of the group include: cancellation of the law, the existence of a single neutral element, inverse single, and theorems that follow.

Building-with refers to the process of combining familiar pieces of knowledge into a new context. It includes recognizing [11]. In other words, building-with is defined as using mathematical structures to achieve a given goal [12]. It reflects recognizing the familiar structure, and using it to solve the new problem. Actually, recognizing and building-with are nested actions where they complete each other. Most often, it is not possible to separate one action from the other. At this stage, combining some properties to get a new concept. The concept of the algebraic structure formed from several previous properties, eg if the set is not empty with certain operations satisfy the closed nature called grupoid. Grupoid that meets the associative nature called semigrup. In other words, semigrup is an empty set with no specific operation that meets the closed nature and associative. At this stage, combining some properties to get a new concept. The concept of the algebraic structure formed from several previous properties, eg if the set is not empty with certain operations satisfy the closed nature called grupoid. Grupoid that meets the associative nature called semigrup. In other words, semigrup is an no empty set with specific operation that meets the closed nature and associative. Monoid adalah semigrup yang memiliki elemen netral. Atau dapat dikatakan himpunan tak kosong dengan operasi tertentu yang memenuhi sifat tertutup, asosiatif, dan memiliki elemen netral. The Group is a monoid that each element has an inverse. Or a set is not empty with certain operations satisfy the closed nature, associative, has a neutral element, and every element has an inverse. While the group that meets the commutativity called abelian group. Abelian group means it meets the closed nature, associative, has a neutral element, each element of the inverse memeiliki, and meet the commutative properties.

Construction is the process of structuring new knowledge, also defined as processes of reorganizing and restructuring. Constructing is the process of restructuring and reorganizing what is recognized and known to construct a new meaning [11]. Reference [13], the process of construction - as the central epistemic action of abstraction comprises vertical reorganized knowledge, and requires theoretical thinking. Constructing is observed when the individual uses the structures he recognizes in solving the problem, given to teach a new mathematical concept. Construction is studied in this research is proving algebra problems. Means the process of reorganizing and restructuring in the proof of algebra problems. Proof algebra problem to show how the statement is true or false and also showed why the statement was true. Example: $G = \{(a, b) \mid a, b \in Z\}$, defined operations in G: $(a, b) \oplus (p, q) = (ap, b + q)$, $\forall$ $(a, b), (p, q) \in G$. Are $(G , \oplus)$ is a semigrup? Semigroup it must meet closed and associative properties. It means to prove (G, ⊕) semigrup means must be proved the truth of whether (G, ⊕) meets the closed nature and associative. To be able to show (G, ⊕) meets the closed nature and associative, means must know the definition of a closed and associative properties. The closed nature (G, ⊕): ($\forall$x, y $\in$G). x ⊕ y $\in$ G, and associative properties (G, ⊕): ($\forall$x, y, z $\in$ G). (X ⊕ y) ⊕ ⊕ z = x (y ⊕ z), this definition does independent on the form of the set and the operation is given.

Referring to the above description, to reveal about the ability of students to construct the proof abstraction algebra problems should be able to reveal the students' ability in recognizing, building-with, and construction (RBC). The problem is how to explore the ability of students to construct proof algebra problems through RBC? For that, the instrument used is not enough just to test, but there must be a supporting instrument that is able to explore the ability to construct the proof algebra problems. The purpose of this study to obtain an interview guidelines as support to explore the ability of students to construct the proof algebra problems.

II. METHODE

This study intends to obtain the supporting instruments of abstraction students in constructing proof algebra problems. To obtain a description of abstraction in constructing the proof problems in algebra, proving tests carried out algebra problems. To explore more about the abstraction, clarification with reference to the results of tests proving algebra problems. Based on these descriptions, this kind of research is exploratory qualitative research with the main data in the form of writing (test results proving a problem) and the words of the task-based interview. Subjects who used the trial is the student of mathematics education UNIROW Tuban have earned subjects algebraic structure.

To obtain valid data, conducted the interview. Interview questions referring to the investigation of abstraction students in constructing proof algebra problems, which have been made in the form of interview guidelines. The methods used are recorded through clinical interviews and audio visual equipment. Clinical interviews are used for capturing information about abstraction students in constructing proof algebra problems as a material to draw conclusions.

Supporting instruments to explore abstraction students in constructing proof algebra problems refer to the RBC (Recognizing, Building-with, and Construction). Topics algebra used is grupoid, semigrup, monoid, and groups. Broadly speaking, interview guidelines for constructing proof explore abstraction algebra problems are presented in Table 1.

TABLE 1. Interview Guide

No	Indicator	Question
1	Recognizing	Example: G = {(a, b) | a, b $\in$ Q^+}, defined operations in G: (a, b) ⊕ (p, q) = (ap, bq), $\forall$ (a, b), (p, q) $\in$ G. Show (G , ⊕) is a grup? a. Give an example of a member of the set? b. Give examples that are not members of the set G? c. Determine the operating results (2, 5) ⊕ (3, 1) = ... d. How is the definition of a group? e. How definitions the closed nature? f. How definitions (G, ⊕) closed? g. How does the definition of associative nature? h. How definitions (G, ⊕) associative nature? i. How does the definition of neutral element? j. How definitions (G, ⊕) has a neutral element? k. How is the definition of the inverse? l. How definitions (G, ⊕) each element has an inverse? and can ask some properties or theorems supporting proof
2	Building-with	This section asks some combination of definition on the part Recognize, eg: a. Is groupoid is semigrup? Why? b. Is groupoid is a monoid? Why? c. Is grupoid is a group? Why?

		d. Is monoid is grupoid? Why? e. Is monoid is semigrup? Why? f. Is monoid is a group? Why? g. Is semigrup is grupoid? Why? h. Is semigrup a monoid? Why? i. Is semigrup is a group? Why? j. Is a group grupoid? Why? k. Is a group semigrup? Why? l. Is group is a monoid? Why? m. What should be shown if it will prove grupoid? Why? n. What should be shown if it will prove semigrup? Why? o. What should be shown if it will prove monoid? Why? p. What should be shown if it will prove a group? Why? And others.
3	Construction	In this section, will explore the ability to construct the proof. After the students are faced with the problem of proof, the questions: a. To prove the above problem, what do you show? Why? b. What do you think, if the proof is not in sequence? Explain! c. How is your conclusion, if one of the conditions there are not proven? Why? d. How do you move to prove the closed nature of the problems mentioned above? Write / explain! e. How is your conclusion, if the closed nature is not fulfilled? Why? f. How do you move to prove the associative nature of the problems mentioned above? Write / explain! g. How is your conclusion, if the associative nature is not fulfilled? Why? h. How do you move to show the existence of a neutral element in the above problem? Write / explain! i. How is your conclusion, if it does not have a neutral element? Why? j. How do you move to show that every element has an inverse? Write / explain! k. How is your conclusion, if there are elements that do not have an inverse? Why? l. Based on the steps proof that you do, what your final conclusion? Why? m. And others.

Furthermore, the trial to students who have earned courses Algebra Structure. Selected as the subject of trial are two students of the AD and the US are female. The problem that used trial: Let G = set of positive rational numbers. Operation is defined in G as follows: $a * b = ab / 3$, $\forall a, b \in G$. Prove that (G, *) is a group!

The trial results were analyzed qualitatively. This results to determine whether a supporting instrument in the form of interview guidelines have been able to measure the ability of students to construct proof abstraction algebra problems (valid). In addition, conducted the validation the validator to determine the accuracy of questions both in terms of content, construct, and the language used.

III. RESULTS AND DISCUSSION

This section describes the trial results and discussion. The trial is to test the interview guidelines of what is already able to explore abstraction students in constructing proof algebra problems. The following profile trial results according to the indicators used, namely: Recognizing, Building-with, and Constructing.

Recognizing

Based on the order of introduction, recognizing refers to the ability of students to know all the facts, concepts that may be used as a knowledge base for proving problems. The problem used is proof of the group. The trial results may indicate that the student is able to recognize some of the facts, concepts that may be used for verification. However, there are some that need repairs sentence, the indicator some students looked puzzled, because do not understand the question. The next sentence made simpler, so the question is more easily understood. Here are excerpts of interviews with AD, after working on the problem proving: Let G = set of positive rational numbers. Operation is defined in G as follows: a * b = ab / 3, ∀a, b ∈G. Prove that (G, *) is a group!

Researcher	Whether the problem is easy to understand?
AD	Yes, Insya Allah
Researcher	What are you trying to prove?
AD	…Group
Researcher	How is the definition of a group?
AD	The set G with operations asterisk ("*") ..., meet closed, associative, and each element has an inverse
Researcher	How the neutral element?
AD	... Oh yes there are four condition, the third condition unkes ("the element of unity")
Researcher	How definitions the closed nature?
AD	Hmmm ... any two elements in G, results of operations stars in G.
Researcher	Good, then how the definition of associative nature?
AD	Each ...., Three elements in G, a result like this ... x star in brackets y z star, together with, in brackets star x y then z star
Researcher	What can be written in symbolic?
AD	Yes sir ... like this
Researcher	If the definition of neutral elements how?
AD	Each element in G ...., Eh not, there is an element e in G, if e star by any element in G results remain
Researcher	Good, how the definition of the inverse?
AD	Hmm ..., every element x in G, there is an inverse x in G, so x star x inverse result is a neutral element e.

Based on the interview excerpt above, it can be said that the subject of AD, is able to reveal the group definition, the closed nature, associative, neutral element, and inverses of an element. This means that, the subject of AD in "recognizing" shows a good ability. Likewise, other subjects such as the US shows the ability of recognizing pretty good. It can be concluded that the interview guides were able to uncover the ability of recognizing. In line with the opinion of [4] recognizing refers to the learner realizing that a specific previous knowledge construct is relevant in the situation at hand. In the quote above is not asking for some theorems related to the group that may assist/support in the proof. However, because of proving problems that used only prove problematic enough group evidenced by definition. Recognizing refers to a familiar structure [11]. Actually that is supportive of the problems evidenced, the student is not enough just to mention the closed nature, associative, neutral elements, and each element has an inverse, but also must be able to know the definition.

Building-with

Building-with refers to the combination of several facts or concepts, thus forming a mathematical structure 'new'. This activity is related to the ability to recognize, if in recognizing less good, then chances are the building-with too less well, and otherwise. Actually, recognizing and building-with are nested actions where they complete each other. Most often, it is not possible to separate one action from the other [14]. Based on trial results shows the ability of the subject building-with fairly good. Here are excerpts of interviews with US after working on the problem proving.

Researcher	Now kindly be informed, if four condition for prove the group, only fulfill one condition ie the closed nature of what can be called a group?
AD	No ... it's called groupoid
Researcher	If the condition is fulfilled only associative nature is called what?
AD	Hmm .... do not know
Researcher	So, how the definition grupoid?
AD	only meets the closed nature.
Researcher	If grupoid meet associative nature, it is called ...?
AD	It…., hmm…. Semigroup
Researcher	How semigrup definition?
AD	Which meets the the closed nature and associative
Researcher	Another definition?
AD	Oh ... yes, grupoid that meets the associative nature.

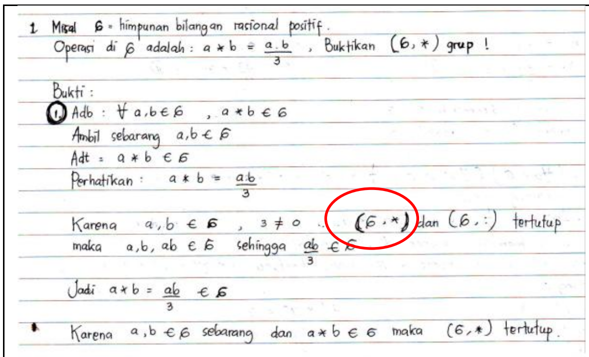
Researcher	Monoid, how the definition?
AD	Hmmm ... .. repeat
Researcher	How does the definition of monoid?
AD	Which meets the the closed nature, associative, and has a neutral element.
Researcher	Try define monoid using groupoid or semigrup!
AD	Monoid mean ... it semigrup which has a neutral element, or ... groupoid which meets the associative nature and has a neutral element.
Researcher	If the group meets commutative properties, it is called ....
AD	It was ... .. the group is commutative, or abelian.

The above excerpts of interviews have shown an ability building-with US. Students are able to show building-with by combining the closed nature, associative, neutral elements, each element has an inverse, and commutative properties. This was in line with [4] building-with comprises the combination of recognized constructs, in order to achieve a localized goal such as the actualization of a strategy, a justification or the solution of a problem. The model suggests constructing as the central epistemic action of mathematical abstraction. Based on these facts it can be said that the interview guides were able to explore the potential of building-with of the subject.

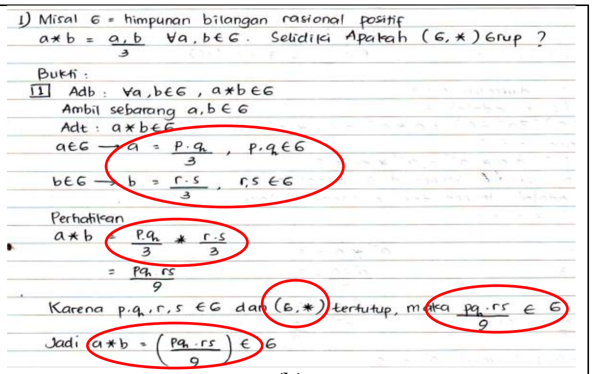
Constructing

This section is the main part in the shows the abstraction students. Reference [4] constructing consists of assembling and integrating previous constructs by vertical mathematization to produce a new construct. It refers to the first time the new construct is expressed or used by the learner. This definition of constructing does not imply that the learner has acquired the new construct once and forever; the learner may not even be fully aware of the new construct, and the learner's construct is often fragile and context dependent. Results of tests on the AD and the US shows the constructing pretty good. Although logically still found a few steps 'no' logical.

The first step, we look at the answers to the AD and the US in proving the closed nature, the first condition for proving the group. In answer to AD, the first step to write the definition of the closed nature of the symbolic; AD means recognizing the definition of the closed nature. But in part the reason (see the sign ellipse) is not logical, because of (G, *) is closed is to be shown the truth. In addition to the operation '*' does not exist, that there is only a.b (multiplication). However, the end result proving the closed nature of the right. (Fig. 1 (a)). Reference [9] explains that a proof of a mathematical theorem is a sequence of steps that lead to the desired conclusion. Rules to be followed by a sequence of steps that made explicit when the logic formalized. Reference [15] reasoning, proof and arguments in the mathematics classroom is an important issue in the study of mathematics education.



(a)



(b)

FIGURE 1. Proof the closed nature, subject AD (a) and US (b)

In answer to US, the definition of the closed nature symbolically it is true, but elaboration of step, membership G, is wrong (Fig. 1 (b)). It is the possibility of the US do not understand about the set of rational numbers, so write if a $\in$ G, then a = pq / 3. Whereas pq / 3 is the operation of p * q. The mistake in defining the membership set, resulting in the end result was wrong. Step illogical conducted AD, also found in the US answer, namely: (G, *). Reference [16] asserts that the proving clearly has the purpose of validation confirms the truth of a statement by examining the logical correctness of mathematical argument. In the second proving, proving the associative nature. (Fig. 2). And the answer of AD, there is a mistake in operating, although the end result, the left side is equal to the right side. Even at the conclusion finally obtained meet asosistif nature, but the proving is considered wrong, because of the conclusion was obtained from the process is wrong. In answer to the US, are correct. In the US proving associative nature, does not elaborate on the membership of G, so as not to make a mistake.

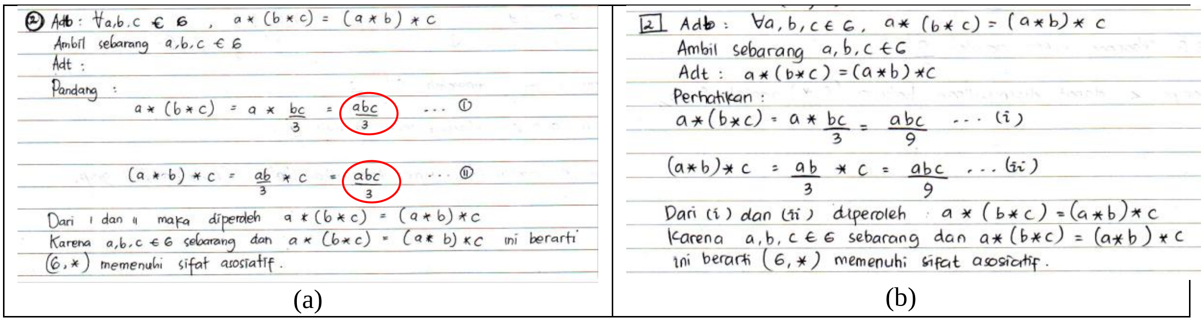


FIGURE 2. Proof of associative nature, subjects AD (a) and US (b)

Noting some of proof do the AD and US, shows that constructing can be found in error, although at recognizing and building-with an excellent result. However, in general, the ability of the students recognizing and building-with good, then constructing would also be nice. Reference [2] a student cannot get to the building-with and construction stages if he cannot "recognize". Also, a student who can "recognize" has to perform both actions of recognizing and building-with in order to "construct". This mechanism is called *the dynamic nesting of the epistemic actions*.

A similar incident occurred when proving the existence of a neutral element, both the AD and the US have an answer that shows the truth logically. Likewise, in answer to proving every element has an inverse, AD and US can shows the logically. Finally, the AD and the US can be concluded well that (G, *) is a group. Here are the answers to the US on proving that every element in G has an inverse in G. (Fig. 3)

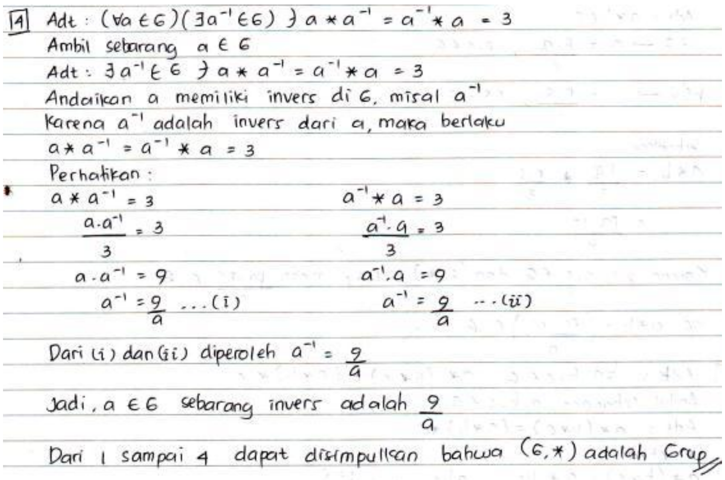

FIGURE 3. Answer US in inverse proving.

Answer US on proving already shows the inverse logical clarity. Likewise conclusion, the proving obtained from: (a) the nature of the closed, (b) associative nature, (c) the existence of a neutral element, and (d) each element in G has an inverse. Conclusion (G, *) proved to be a group. If we look closely, step proving carried US, especially on the proving the closed nature, there are some steps that are not logical. But at the end of proving, the conclusions obtained proved to meet the closed nature. As a result, all that is conditioned to shows a group can be met, so the conclusion (G, *) is a group.

IV. CONCLUSION

Abstraction is a vertical reorganization activities mathematical concept which had been constructed earlier to a new mathematical structure. Mathematical concepts combined, restructured, organized and built up to more abstract or more formal. How to test the student abstractions in constructing the proof? In this study using a model Recognizing, Building-with and Constructing (RBC). *Recognizing* refers to a familiar structure. Recognizing occurs when the student realizes that the construct that is familiar from a previous activity is connected to or relevant for the mathematical situation in the present activity. *Building-with* refers to the process of combining familiar pieces of knowledge into a new context. In other words, building-with is defined as using mathematical structures to achieve a given goal. *Construction* is the process of structuring new knowledge, also defined as processes of reorganizing and restructuring. Constructing is the process of restructuring and reorganizing what is recognized and known to construct a new meaning. To explore the potential of students in constructing proving abstraction algebra problems using RBC models. Supporting instruments which refers to the RBC models designed interview guidelines. Based on the analysis, the research concluded: *Recognizing*, students tend to be able to know a few facts, concepts that support the proof problem, for example: the definition of the closed nature, associative, neutral element, inverse of an element. Students are also able to explain the definition of grupoid, semigrup, the group very well. *Building-with*, students tend to be able to combine the concept of the closed nature, associative, neutral element, inverse of an element, in defining grupoid, semigrup into new contexts that are interrelated. Students are also able to combine the definition of the group, monoid, semigrup, grupoid, and abelian groups. *Constructing*, students in constructing proof algebra problems still many steps that are illogical in the use of facts or concepts. For example: the show proof enclosed nature illogical in its operations; proof neutral element of found the steps that are not rational. As a result, proof tends to incorrect, although ultimately correct conclusion. So the proof construction algebra problems in declared less successful, because the conclusions derived from evidentiary less logical step.

ACKNOWLEDGMENT

The author would like to thank the Director of Research and Community Service, Directorate General for Strengthening Research and Development, Ministry of Research, Technology and Higher Education that has provided research costs. And also the Chairman of the Institute of Research and Chairman of the Mathematics Education UNIROW Tuban who have given permission for research.

An Analysis of Student's Error in Solving PISA Problems

Yurizka Melia Sari[1], Erik Valentino[2]
[1 2]STKIP Bina Insan Mandiri (Program Studi Pendidikan Matematika)
yurizka.melia@gmail.com

Abstract— Based on PISA survey in 2012, Indonesia was only placed on 64 out of 65 participating countries. The survey suggest that the students' ability of reasoning, spatial orientation, and problem solving are lower compare with other participants countries, especially in Shouth East Asia. Nevertheless, the result of PISA does not elicit clearly on the students' inability in solving PISA problem such as the location and the types of student's errors . This case would consider on further research in finding students' error in solving PISA problem including its type and location. Therefore, analyzing students' error in solving PISA problem would be essential countermeasure to help the students in solving mathematics problems and to develop scaffolding. This paper will discuss the categories of the students' error analysis based on Newman analysis that consist of of reading and decoding, comprehending, transforming, processing and encoding. The result obtained from junior high school in Surabaya support categories on students' error from each four different context as (1) personal, (2) occupational, (3) social, and (4) scientific. Baed on the analysis of the study, it is found that there are 5 types of error which is made by the subject. They consist of reading error, comprehension error, transformation error, process skill error, and encoding error. The most common mistake that subject do is encoding error with a percentage of 26%. While reading is the fewest errors made by the subjects that is only 12%. Both transformation and process skill errors have the same percentage of the number of mistake is 24%. Lastly, 14% of the made mistake is in comprehending PISA problem. In the other hand, the context of PISA problem which has the most error is scientific context with a percentage of 43%. While occupational context problem has the fewest mistake which is only 12%.

Keywords: *Analysis of Student's Error, PISA, Newman Analysis.*

I. INTRODUCTION

Program for International Student Assessment (PISA) is a program for assessing student's ability in International scope that was managed by Organisation for Economic Cooperation and Development (OECD). One aspect that assessed by PISA is the ability of students to apply mathematical context in variety situations in daily life. Therefore, PISA instruments is the real problems that require the ability in reasoning, spatial orientation and problem solving (OECD, 2013a).

In 2012, the result of OECD show that Indonesia was only places on 64 out of 65 participating countries in mathematics context which only gained 375 points. It suggest that Indonesian students ability in employing mathematics knowledge in their life is low. In the other hand, OECD stated that mathematics is strong predictor of a person's success in his youth. Moreover, it also affects the ability of class participation and the expectations of future earnings.

In fact, student's inability in solving PISA problem is caused by the lack of student skill in modelling daily life sentences into mathematics sentences. Moreover, this is also supported by the role of teachers in which they do not realize their mistakes in learning process that make student's errors in solving mathematics. The teachers tend to give the problems and the direct formulas without connecting the situations of daily life and mathematics concepts. As a result, students become confused and make mistakes in solving the next level of PISA problems.

To sum up, it is beneficial for Indonesia to improve PISA scores in subsequent years. For these improvements, we are interested in analyzing student's errors in solving PISA problems, especially in the matter of mathematics. These activities will provide an overview of student's thinking in solving PISA based on their erros's analysis. Hence, these results can be used as the references to make improvement in mathematical student's ability of PISA level.

Regarding to the purpose of the study which is to describe the types and the location of errors in solving PISA problems, there are benefits of this research as follows: (a) For lecturers, this study can be used as consideration in determining topic of student's thesis or final projects in their lecture, and (b) For mathematics teachers, this study can be used to determine the action plan to overcome student's mistakes in solving mathematics PISA problems by developing a model or a method of mathematics learning.

II. RESEARCH METHODS

This study is an exploratory research by using qualitative approach hence it will generate descriptive data such as the desription of the types and the location of student's errors in solving PISA problem, which is amounted 4 questions. In this study, researchers act as observers and interviewers to determine student's mistake in solving PISA problem.

This study was conducted in SMP Muhammadiyah 17 Plus Surabaya in the even semester of 2015/2016. The research subject is the selected students in 8^{th} grade which is determined by their mistakes in solving PISA problem. The problems is adjusted to each content in PISA 2012, namely change and relationship, quantity, space and shape, and uncertainty.

There are three phases of a qualitative research approach, namely the preliminary phase, the core phase and the data analysis phase.

A. The Preliminary Phase

The researcher made an agreement with mathematics teacher of research's subjects and discussed about the mathematical content which has been obtained by the students who will be research subjects. The next activity is the preparation of research instruments. In this study, the main instrument is the researcher due to the fact that we are a determinant in research process and an observer in colecting data in the field, such as in-depth interviews on the subject to obtain the necessary information in data collection. Whilst, the other instruments that has been used in this study are PISA Test Problem and Interview Guidelines. PISA test problems is arranged to reveal student's error in solving PISA problem which is rarely gotten by the students. While interview guidelines instrument is prepared to identify the mistakes that was done by the students when they solved PISA problem and to probe their reason of their errors.

B. The Core Phase

This activity begins with the selection of research subjects based on the result of PISA test that was given earlier. Each subjects represents a type of error according to Newman analysis. In addition, the subjects is also based on the communication skill and the similarly mathematical ability. The communication skill meant that student had no difficulty when communicate orally and be able to express his opinion. The next activity is doing semi-structured interview with the selected subjects in more depth in order to verify the result of data recorded. As a result, both the interview data and PISA test data are the initial data to do the analysis of data.

C. The Data Analysis Phase

The purpose of this phase is arranged the data be structured sytematically and easily intrepeted. Actually, the data analysis will be done using descriptive analysis to disclose student's errors in solving PISA probem which is refer to Newman analysis. In addition, there three stages of analysis data process, namaely data reduction stage, data exposure stage and drawing conclusion stage. The former refers to sharpening process, selecting, focusing and transforming the obtained raw data. Then, it will be selected, simplified and grouped with the corresponding data in order to answer the research question. The second stage is classifying and identifying the set of organized data in the form of narrative text, charts and others hence it is possible to draw a conclusion. As a result, the set of data that has been reduced, classified, identified is allowing the researcher to draw conclusions on the analysis of student's error in solving PISA problem which is refers to Newman Analysis.

III. RESULT AND DISCUSSION

There are 5 students that have been selected as research subjects. It can be clearly seen that their response in solving PISA problems have been analyzed and categorized into Newman's 5 types of errors. Then, the type of error made by the subject will be discussed further on the error's analysis which are made by each of them. Here is a discussion of the error analysis of each subject when they solved PISA problem with different contexts.

Explanation:

: Uncorect Student's Response with Newman's Error Analysis

: Correct Student's Response

: No Response

Based on their general response in solving PISA problem with 5 different context, the most mistake that have been done by them is encoding error with percentage of 26%. Then, the another error that has the lowest percentage is reading error with 12%. While, 24% of mistakes are process skill error and transformation error. The remaining 14% of the made mistakes is comprehension error.

In the other hand, the PISA context which has the most error is scientific context with a percentage of 43%. Meanwhile, occupational context problem has the less mistake that is only 12%. Then, personal context problem and social context problem consequtive has an error percentage of 21% and 24%.

A. Reading Error

Reading error is a condition when subjects have difficulty with reading and hard to establish a context for a particular text, predict its grammatical structure and predict the meaning of the text. In this study, subjects do mistake in reading the main information of the problem hence they did not apply its information in solving problem. Moreover, reading error done by subjects in scientific and personal context of PISA problem.

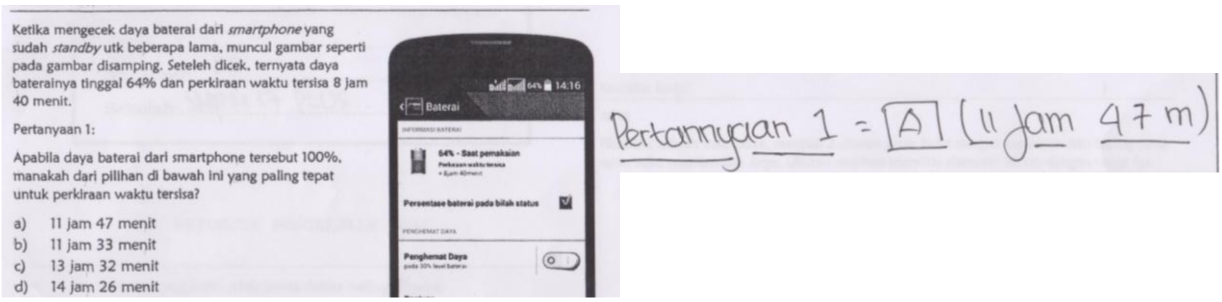

FIGURE 1. SD'S RESPONSE ON SCIENTIFIC CONTEXT OF PISA PROBLEM

Based on the result, SD did not apply the information on the question due to the fact that he did not read the main information. Moreover, based on the interview, he said that he didn't know the meaning of "standby" on the question hence he decided to choose option A.

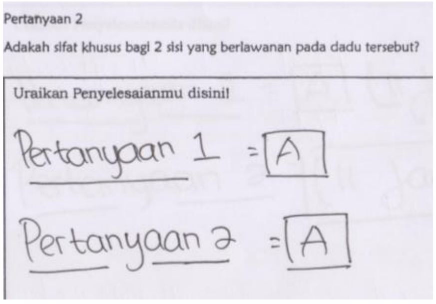

FIGURE 2. SD'S RESPONSE ON PERSONAL CONTEXT OF PISA PROBLEM

Based on SD's response on personal context of PISA problem, his response is not accordance with the question which he have to explain about the special characteristic of the opposite dices . Based on the interview, subject argued that the answer of question 2 is equal to the question 1, so he decided to choose option A as his answer.

B. Comprehension's Error

Comprehension error is a mistake when subject missunderstand what the problem ask and collect information from the problem insufficiently. In solving PISA problem, subject perform coprehension error on the saintific and social context of PISA problem. In the following is the subject's response on those context with the explanation. .

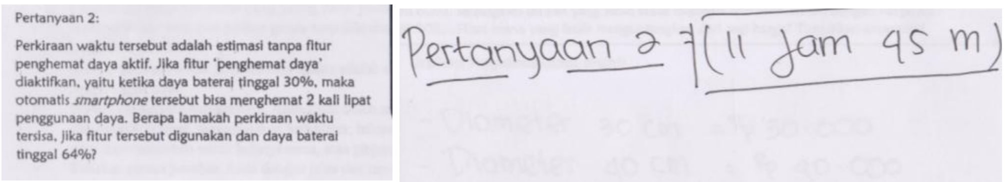

FIGURE 3. SD'S RESPONSE ON SCIENTIFIC CONTEXT OF PISA PROBLEM

Based on interview, SD does not comprehend the meaning of the queston implicitly between "fitur baterai" and "penghemat daya" hence SD only write the answer based on alternative response provided in question 1.

.

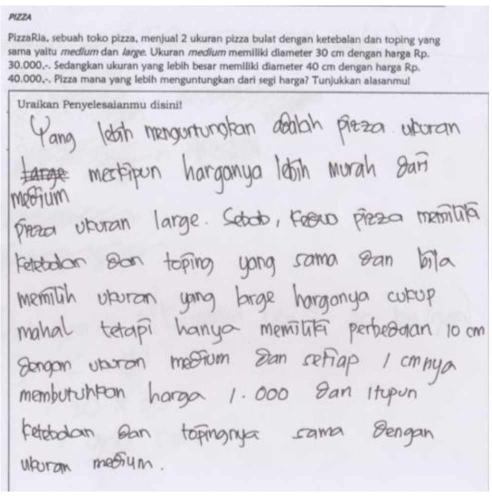

FIGURE 4. SC'S RESPONSE ON SOCIAL CONTEXT OF PISA PROBLEM

ISBN 978-602-74529-0-9

SC also make a mistake in comprehending PISA problem on social context. Based on the interview, SC missunderstand with what question ask about “menguntungkan’. Therefore, subject got confused in writing an appropriate solution.

C. Transformation’s Error

Transformation error is a mistake when subject can not change the question into mathematics model correctly. This mistake occurs in all contexts of PISA problem where two questions which get the most error is on social and scientific context..

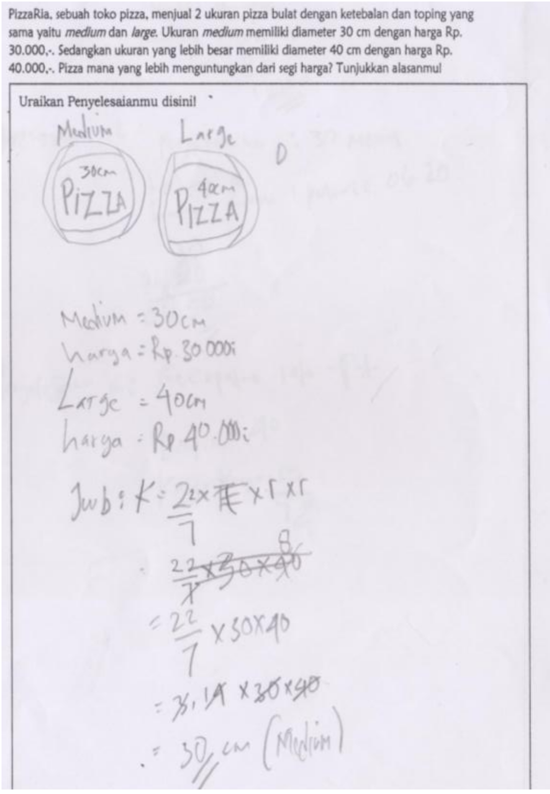

FIGURE 5. SE’S RESPONSE ON SOCIAL CONTEXT OF PISA PROBLEM

Subject make transformation error when he write the area of circle by “ $K = \frac{22}{7} xrxr$ ” with r_1 = 30 cm and r_2 = 40 cm. In fact, the area of cicle must be written in symbol “L” and the radius have the equal length.

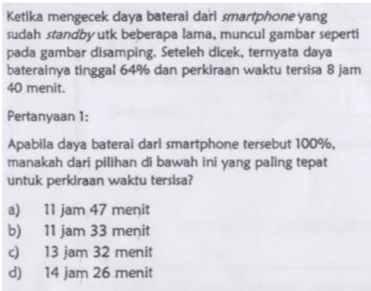
D. Process Skill Error

Process skill error is a mistake occuring because subject does not master in calculating mathematically. Therefore, this mistake make the subject give the response uncorrectly. This study suggest that the most error in process skill occurs on social and scientific context of PISA problem.

In figure 5, SE do a mistake in multiplication process “3.14 x 30 x 40 = 30 cm”. In interview process, SE stated that subject cancel out the same number are 3 and 4 such that 30 obtained from the calculation. In addition, subject also stated that his teacher commonly used thus method in division process so subject consider that cancel out method can be used in multiplication process.

E. Encoding's Error

Encoding error is a mistake when the subject write the final answer which is not accordance with what question ask. In this study, PISA context problem which getting the most error in encoding answer are social and scientific context.



Ketika mengecek daya baterai dari *smartphone* yang sudah *standby* utk beberapa lama, muncul gambar seperti pada gambar disamping. Seteleh dicek, ternyata daya baterainya tinggal 64% dan perkiraan waktu tersisa 8 jam 40 menit.

Pertanyaan 1:

Apabila daya baterai dari smartphone tersebut 100%, manakah dari pilihan di bawah ini yang paling tepat untuk perkiraan waktu tersisa?

a) 11 jam 47 menit
b) 11 jam 33 menit
c) 13 jam 32 menit
d) 14 jam 26 menit

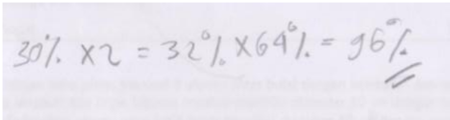


FIGURE 6. SE'S RESPONSE ON SOCIAL SCIENTIFIC OF PISA PROBLEM

Based on the subject work, the answer 96% is not accordance with what the problem ask about how long the remaining times in times unit. Based on the interview, subject consider that the answer of question 2 is about the percentage of the remaining time.

IV. CONSCLUSION AND SUGGESTION

Based on the result, it is found that there are 5 types of mistakes made by the students namely reading error, comprehension error, transformation error, process skill error and encoding error. The most common mistake which are have been done by the subjects is encoding error with a percentage of 26%. While reading is the fewest errors made by a subject that is only 12%. Both transformation and process skill error possessed the same percentage of the number of errors is 24%. The last, 14% of the made mistakes is an error in understanding the problem of PISA.

In this study, PISA problem is adopted from PISA 2012 where the predominant domain is mathematics. Thus, there are 4 selected PISA problem that each question has a different context namely social, personal, occupational and scientific. PISA Problem with the most errors is scientific context with a percentage of 43%. Meanwhile, PISA with occupational context contains only 5 out of 42 errors. The rest, both personal and scientific context in succession problem has a percentage of error of 21% and 24%.

Based on the conclusions, the writer can provide input for other researchers, teachers, students and schools. For other researchers, they need to analyse further on-students error in solving PISA problems that have different content. As for teachers, it is required the learning of PISA types of problems in mathematics teaching so that students are familiar with the form of the question. In addition, students should also be open to their teachers if experiencing difficulty when doing on math problems.

ACKNOWLEDGMENT

This research is financially supported by Indonesian Directorate General of Higher Education (DIKTI). Essentially, this study is a part of research granted by PDP Grant "Penelitian Dosen Pemula Desentralisasi" DIKTI year 2016 with the number of contract 101 P2H/P/K7/KM/2016.

Integrating Technology in Inquiry Based Learning

Aprilia Dwi Handayani
Mathematics Education Department, Universitas Nusantara PGRI Kediri
handayani_dwi_aprilia@yahoo.com

Abstract— There are two important things to be of interest in accordance with the vision of NCTM in mathematics education, ie knowing mathematics in the 21st century and the need to continue enhancing the role of mathematics education to answer the challenges of a changing world. One of the competencies associated with the great challenges of the 21st century is benefiting from the support and tools (including IT), such as: know the existence and nature of the various tools for mathematical activity. In the era of technological advances such as the current graphics software support is very abundant and can be used as an attempt to improve the learning outcomes of mathematics learners. In addition, the student of Mathematics Education as a pre services teacher should receive the widest provision in the control or utilize the skills of computer software, in order to answer the demands in the job market. This paper describes the integration of technology in the inquiry based learning at the college level. Thus, the integration of technology in inquiry based learning in mathematics is expected to generate a deeper understanding and flexible in accordance with the development of education that can't be separated from the development of technology.

Keywords*:* *technology, inquiry based learning*

I. INTRODUCTION

The progress and development of technology was integrated into many life area's, including economics, health, transportation, education and the others. The use of technology in various fields of course adapted to each field. In the education, technology comes in many forms. Computer as a part of technology can act as a instructional media to facilitate the learning process as well as separately instill the concept to students.

NCTM's vision shows the importance of two things in mathematics education, there are to know mathematics in the 21st century and the need to continue to improve mathematics education to answer the challenges of a changing world. One of the competencies associated with the great challenges of the 21st century is benefiting from the support and tools (including IT), such as: know the existence and nature of the various tools for mathematical activity [1]. In the era of technological advances such as the current graphics software support is very abundant and can be used as an attempt to improve the learning outcomes of mathematics learners. In addition, students of Mathematics Education Programs as a pre services teacher should receive the widest provision in the control or utilize the skills of computer software, in order to meet the demands in the job market. Learning Differential Calculus accompanied by "Mathematica" produce satisfying achievement for students indicated 88% of students receive a minimum value in the category B- or thoroughly studied and the increased independence of student learning (Listyani, Dhoruri, and Setyaningrum, 2006).

Other standards that must also be met by a math teacher is the knowledge of technology. A prospective teacher should be able to take advantage of technology as an important part in the learning of mathematics. An indicator of the standard of knowledge about the technology are: 1) using mathematical knowledge for selecting and using appropriate technology, but not limited to worksheets, dynamic graphics tools, computer algebra system, statistical tools, dynamic graphing calculators, data collection tool and software presentation.

Inquiry mathematics is a learning model that encourages students to organize their own activities while learning math statement. In the inquiry mathematics, students take responsibility for directing the lesson with the teacher guiding the activities undertaken mathematics students in the classroom.

The involvement of students in inquiry mathematics starts from asking a question, make a conjecture, plan and monitor the activities of their mathematics, explored the idea in collaboration with friends, to identify when they will " requires new knowledge, ask the teacher about the mathematics they learned, explaining the reason answer and prove the results of their answers. While activity in the inquiry mathematics teachers are utilizing the curiosity of students, linking concepts and procedures, motivate students, to build an open inquiry, combining different forms of reasoning, develop initiative, independence and leadership students. According [2] guided inquiry learning methods lead to active participation in the learning process. This learning method improve students' ability to analyze, synthesize, evaluate and relate the concepts contained in the various disciplines of learning and everyday life, thus causing material studied more relevant for students.

II. Discussion

Based on the above introduction, the discussion in this paper will focus on the integration of technology in learning inquiry.

A. *Inquiry Based Learning*

Inquiry is a term that is used both in education and in everyday life to describe how to find the knowledge or information by asking questions. Inquiry mathematics present clear similarities with scientific investigation [3]. As scientific inquiry, inquiry mathematics began from a question or a problem, and the answer is sought through observation and exploration; conduct experiments; make the connection; recognize the corresponding mathematical techniques when needed.

In the Primas Report, inquiry described as a deliberate process ranging from diagnosing problems, critiquing, experiments, and distinguishing alternatives, planning investigations, researching allegations, searching for information, constructing models, debating with peers, and forming coherent argument. Use of Inquiry Based Learning is good for mathematics and science education.

In inquiry learning, educator role as provocateur, means teachers (educators) served to motivate the students to develop initiative, independence and leadership as well as arouse the curiosity of students. Curiosity beginning students to conduct an investigation is one of the great challenges in Inquiry-based learning. In this process, educators play an important role. Teachers contribute and expand ideas, how to question and how to investigate a person's ideas or theories. Teachers should find creative ways to introduce students to ideas and subject matter that interests them and offer the potential inquiry or provide an opportunity for students to engage in the ongoing Inquiry. When individuals and small groups of students took a different approach to certain questions thoroughly in the classroom, the teachers develop classroom culture where there are ideas that emerged from each student. By hearing the views of others, students have a better understanding of their own ideas and approaches to questions and issues.

According [4], Learning inquiry provides the opportunity for children to develop the knowledge, skills, and habits of thought that lead to a deeper understanding of their world and human experience. The process of inquiry focused on developing an interesting question, which is formulated by the teacher and the child, motivating and guiding questions into topics, issues, and issues related to the content and outcome of the curriculum.

Inquiry learning is more than a simple learning method. Learning inquiry is a philosophical approach to learning and teaching, based on research and constructivist methods, involving children in the investigation that led to the disciplinary and transdisciplinary understanding. Learning inquiry built on curiosity and wonder inherent in children, backgrounds, interests, and experiences. The process provides an opportunity for children to be active participants in a collaborative quest to acquire meaning and understanding. Children who engage in inquiry activities as follows: 1) building a knowledge and a deep understanding, not just passively receiving knowledge, 2) directly involved in the discovery of new knowledge, 3) find ideas that contradict that transform knowledge and previous experience into a deeper understanding, 4) transferring new knowledge and skills to the new situation, 5) is responsible for on going learning and mastery of content and skills curriculum.

Inquiry learning motivate children to explore topics in a meaningful context. The investigation process is not in the steps rigid, but flexible and recursive. Experienced teacher inquirers will move back and forth through the process cycle as new questions arise and the children become more comfortable with the process.

Questions of good questions formulated in a broad and has many possibilities. They encourage children to explore, gather information, plan, analyze, interpret, synthesize, solve problems, take risks, make allegations, concluded, documenting, reflecting learning, and develop new questions for further investigation [4]. As educators, teachers are faced with the challenge and sensitivity in engaging students in learning so that they develop the skills and knowledge they need for daily life.

According [5], the method of inquiry can be done through expository, groups and individuals. In the method of inquiry, the final results are found students is something new for him and also not known by the teacher. In this method, in addition to sebgai guides and counselors, teachers also become resources necessary data. Students still have gathering additional information, make a hypothesis and test it. Examples of topics for inquiry in schools is to determine the density of traffic at the intersection, determine the wasted water from the faucet plumbing damaged, determines much water a river stream.

One of the goals of teaching with inquiry is for students to know and be able to transferring knowledge into other situations. This method consists of four stages, namely: 1) teachers stimulate students with questions, problems, games and puzzles, 2) In response to the stimuli it receives, the students determine the procedures seek and collect information or data that is needed to solve the question, statement and problems, 3) Students appreciate the knowledge gained by the new inquiry conducted, and 4) Students analyze methods of inquiry and procedures found to be a general method that can impose on other situations.

Learning inquiry is one based on the constructivist learning. Mathematics merely as a tool for thinking, the main focus of learning mathematics is to empower students to think construct mathematical knowledge discovered by experts earlier [5]. According [5], mathematics learning approach is the way in which the teachers in the implementation of learning to the concepts presented can be adapted by the students. There are two types of approaches in the learning of mathematics, which is an approach that is methodology and approach are material. While this method of learning is a way of presenting the material is still common, for example, a teacher presents the material with a dominant submission verbally and once in a while there is a question and answer. Each teacher can do a lecture as it was in accordance with their respective fields.

According to Justice et al (2002), inquiry learning process is a cycle in which the students are involved in a topic, develop a question to be explored, determine what information is necessary, collect data, synthesize inventions, discoveries and evaluate the immediate success communicate the inquiry process, students are trained to choose a self evaluation and self reflexion, which is a product of the process of inquiry and permitting success at each stage.

B. Using Technology in Inquiry Based Learning

The rapid development of computer technology and communication brings also bring development and change in people's lives. It is not least also affect the role of technology in the development of education. In the education sector of education, the computer is a multi-functional tool that can be used in teaching and learning. Furthermore, the computer helps in distinguishing the role of students and teachers, apply the same standards of learning [6]. Software can also equate education and encourage student understanding and meaningful learning for all students in a constructivist approach. Teacher-centered learning spontaneously become student-centered when the atmosphere multiple intelligence implemented in educational activities through the use of computers [7].

As in other areas of life, the use of computers in mathematics learning is growing by leaps and bounds. However, the characteristics of users and many other variables that describe various types of use of technology in learning mathematics. At first, teachers and educational researchers think that kompuetr is a support tool in learning as well as priyektor screen, slide or television. Computer applications used initially only used to present the electronic pages with colorful pictures and simple calculations compared to computer role in guiding students to construct their own knowledge [6]. If the computer is only used traditionally, for example for a simple calculation, then it will give a bad impact on the results to be achieved in learning. Traditional computer usage, for example, according to Nocliffe [8], when the computer is used as a calculator in learning algebra, where students can only see the results with a simple calculation. The results show that students lose their ability in algebra calculations when they only use the computer as a simple calculation tool.

In the era of today's educational progress, many teachers and lecturers who incorporate technology into the classroom. In better teaching of mathematics, the use of technology in the classroom to make high-level math activities can be more easily accessible to students. In this case, the technology can strengthen students' learning process, by presenting the content of numerical, graphical, and symbolic without spending time to calculate complex computing problems manually. Technology can also help to encourage students acquire skills and abilities to make connections between concepts so finding solusinyai and proven process pengerjaannnya [9]. This technology can also help students to make connections between mathematics with real contexts outside of mathematics to make the learning process more realistic in the context of [9].

According to Okur, et al [6], one of the significant challenges in mathematics teaching and learning is how to teach students about abstract concepts. In this case, technology in mathematics learning software can be used more broadly to instill abstract concepts in mathematics. With the software mathematical some materials that are difficult to explain, it can be more easily delivered to students. In addition, according [10] the technology can also be used for troubleshooting, eg in advanced calculus courses, students often have difficulty in determining a region integral to the integral llipat three. With the use of software Maple in learning, the student's difficulties can be overcome, so that students can more easily determine sketches, regional integration and function integration.

The use of technology in learning mathematics in general aims to assist students in learning, such as helping students understand the concept, invented the concept, oenguatan concept, and as a means to train thinking in problem solving. There are several role of the use of computer technology in learning, is as follows [10]:

1. Technology as a tutorial for students, which means that the technology used for materitertentu menyampaiakn or explain to the students and the material is presented in a computer.
2. Technology as drill and practice, which means that the technology can be used untukmenguji level of knowledge or understanding of the students after learning of the material.
3. Technology as simulations in learning, which means that the technology can be used to demonstrate or demonstrate an idea or concept.
4. Technology as a tool or media in learning because it has the nature of trial and error to solve a problem.
5. Technology can be used in problem solving.

According to Justice et al (2002), inquiry learning process is a cycle in which the students are involved in a topic, develop a question to be explored, determine what information is necessary, collect data, synthesize inventions, discoveries and evaluate the immediate success communicate the inquiry process, students are trained to choose a self evaluation and self reflexion, which is a product of the process of inquiry and permitting success at each stage.

The use of technology in the inquiry can be done when students explore the necessary information, collecting data and synthesize its findings or evaluating the results obtained and communicate it to classmates. In addition, when there is a mathematical problem that is presented to the students, then the students can also use the technology for solving the problem. For example, in advanced calculus courses, students usually have difficulty in determining the regional integration of the triple integral. The role of technology in this case, for example in the form of Maple Software which is one of the software in mathematics, which is to sketch the graph, so that students easily determine the area of integration and determine the shape of the function to be integrated. By using inquiry learning that utilizes the aid of computers, the students are trained to capture information from maple software in the form of a chart to determine the area of integration. At the stage of communicating the results, students can display the answer that has been gained by using software (eg, displaying graphs and calculation results) or you may also use powerpoin. Thus, the integration of technology in inquiry based learning in mathematics is expected to generate a deeper understanding and flexible in accordance with the development of education that can't be separated from the development of technology.

III. CONCLUSSION

There are several conclusions that can be drawn from the above description, is as follows:

1. One of the significant challenges in mathematics teaching and learning is how to teach students about abstract concepts. In this case, technology in mathematics learning software can be used more broadly to instill abstract concepts in mathematics. With the software mathematical some materials that are difficult to explain, it can be more easily delivered to students.
2. There are several role of the use of computer technology in learning: Technology as a tutorial for students, Technology as drill and practice, Technology as simulations in learning, Technology as a tool or media in learning because it has the nature of trial and error to solve a problem and Technology can be used in problem solving.
3. inquiry learning process is a cycle in which the students are involved in a topic, develop a question to be explored, determine what information is necessary, collect data, synthesize inventions, discoveries and evaluate the immediate success communicate the inquiry process, students are trained to choose a self evaluation and self reflexion, which is a product of the process of inquiry and permitting success at each stage
4. The use of technology in the inquiry can be done when students explore the necessary information, collecting data and synthesize its findings or evaluating the results obtained and communicate it to classmates. In addition, when there is a mathematical problem that is presented to the students, then the students can also use the technology for problem solving.
5. the integration of technology in inquiry based learning in mathematics is expected to generate a deeper understanding and flexible in accordance with the development of education that can't be separated from the development of technology.

Characterization of Spontaneous Examples Based on Teacher and Student Thinking Interaction in Mathematics Learning

Baharullah, Purwanto, Subanji, Edy Bambang
Universitas Muhammadiyah Makassar
Universitas Negeri Malang
Baharullah.fkip@yahoo.co.id

Abstract— When the teachers teach the material in course of study, teacher must be master the subject matter that will be given to students. And when the student will determine concepts that will constructed of material being taught by teachers, students can interact with the teacher to solve a problem, then student will communicating about its opinions so that students find the right solution. At the this interaction activity are among of teachers and students going on interaction process thinking in solving the problems appropriately. This research investigated the characteristics of spontaneous example through thinking interaction of teachers and students in the learning of mathematics. Spontaneous example is an example of is modified or produced by teachers spontaneously. In that case this, how the thought processes the teacher and students to the thinking processes generated spontaneous example and explained by the teacher in course of study of mathematics. The main objective in this study was to assess the characteristics of spontaneous example by thinking interaction Teacher and Student in the learning of mathematics. The results of the research shows that by the thinking interaction of teachers and students in spontaneous example in the mathematics, has produced characteristics of spontaneous example illustrations. In an illustrative example spontaneous consist of 3 (three), namely: (1) simple; (2) equivalent; and (3) expansion (expansive)

Keywords: *thinking interaction, spontaneous example , and mathematics learning*

I. INTRODUCTION

In learning activities are teacher interaction with students that involves thinking of students. This interaction should not rule out the thinking of students. This is due to the thinking of students will determine the form of a concept built by students during the learning activities. Therefore, in the learning of teachers should also pay attention to the thinking of students being able to determine a concept that will be built during the students' learning activities. When the concept was built by students in accordance with the material being studied, the learning objectives have been achieved.

Some research results emphasize the importance interaction in the learning process of mathematics (Elbers, 2003; Steinbring, 2005; Nührenbörger & Steinbring, 2009; Tucker & Harden, 2012). According to Webb (Nührenbörger & Steinbring, 2009) that the interaction of students with regard to solving the problem through the example influential on the results studying mathematics. Nevertheless, the interaction of teachers and students in mathematics, especially the thinking interaction Teacher-Student in learning of mathematics is still less attention.

Thinking interaction in mathematics instruction, as described above, has a great potential to improve student achievement. It is therefore, reforms should how to develop thinking interaction teacher-student in the learning of mathematics, so can be used to improve student achievement, particularly teacher-student thinking interaction associated with the use of examples in mathematics learning. Role of the process of thinking for teachers is to interpret and translate complex concepts to a level appropriate to the student learning experience. It is important that teachers must first develop an understanding of the material will be given to students. When teachers do not fully understand the material well then he will not be able to teach well (Lederman, et al, 2000). This becomes a serious problem when the concepts are incorrectly delivered to students as a result of a lack of understanding in-depth knowledge of teachers of subjects Sanders (Deborah et al, 2005)

Choose and produce examples in teaching, are often needed in the decision-making during an interaction of thinking in the classroom. In the interaction of thinking, the quality of mathematical knowledge of a teacher dijarkan affect what and how to teach. Zodik & Zaslavsky (2008) argued that knowledge of student learning refers to teachers' understanding of how students can know and how students can construct knowledge there is to gain new knowledge. Furthermore, Simon (1995) connects the teacher's knowledge, pre-planning instruction thinking, and interaction in the classroom that fact often hold spontaneous action. The spontaneous action leads to modification or construction of a new sample, which is often called spontaneous example.

Spontaneous sxamples of raised when students do not understand the material identified by the teacher, or when students make mistakes, or when students may discuss and occurs understanding different concepts, or perhaps when her students respond or claim the teacher's explanation. Zodiac & Zaslavsky (2008), suggests a spontaneous case of the example shown in situations where teachers have a clear plan for a lesson, but no specific examples.

However, the use of examples in mathematics learning, in particular the of spontaneous example still received less attention. As noted Zaslavsky (2011) that in spite of the important role the example in learning and teaching of mathematics, only a small number of research focuses on examples teacher selection and treatment exsample. Similarly, there has been no in-depth studies that reveal the interactions thinking teacher-student that focusing on of spontaneous example.

Questions and Purpose Research

The research question is how the characteristics of spontaneous example based thinking interaction teachers and students in mathematics learning ?. And the purpose of this study was to explores and characterization of spontaneous example based thinking interaction teachers and students in mathematics learning.

II. METHODOLOGY

A. Technique Data Collection

Procedure / stage of data collection is done as follows: (1) the preparation phase, researchers introduced various matters associated with the planned research, including research instruments to check the readiness and determination of research subjects, (2) the data collection phase during the learning process. All the learning process observed and recorded using audio-visual (handycam), well by the time teacher explaining or discuss examples the chalkboard or when the students pay attention to the teacher explanation.

B. Techniques Data Analysis

Data that has been collected and are still in the form the recording, then transformed into the shape of a transcript. Process data analysis in this research is a modification of qualitative research the needs analysis that was developed by Creswell (2010), with the steps as follows: (1) manage and prepare data to be analyzed, (2) read the whole data set, (3) analyzing greater detail with mengcoding a data, (4) decrypting a data, (5) the presentation of data within a narrative / qualitative reports and (6) to interpret or interpret the data.

III. RESEARCH RESULT

Teacher and student were become subjects in this study, will describe how the process of thinking interaction teachers and students in the process mathematics learning in the classroom. Teachers who become research subjects are Mathematics Teacher Junior High School country seven Makassar, while students were become research subjects are grade students of nine Junior High School country seven Makassar.

Teacher explains the material about the rank fraction, teacher implementing a method debriefing in course of study so the atmosphere of in the process learning make students more active. When Master give examples linked to material identified, teacher often refer some of the students for answering the example. Similarly, teacher many give examples (including examples of spontaneous) when explaining lesson material.

The following is presented results of thinking interaction between Master and students. Present was presented with a transcript of the recording process of learning mathematics in the rank of material fractions.

Teacher: Note the following properties, (write 1. $p^{\frac{m}{n}} = \sqrt[n]{p^m}$)

Teacher: What is below (showing n at the $p^{\frac{m}{n}}$) ascend to the rank of roots (pointing $\sqrt[n]{p^m}$) the above (pointing m the $p^{\frac{m}{n}}$) becomes rank number $\sqrt[n]{p^m}$

Teacher: It is nature of following (write down 2. $\sqrt[a]{p^b} = p^{\frac{b}{a}}$)

Teacher: (explaining example) Simplify: 1) $5^{\frac{2}{3}}$ 2) $9^{\frac{4}{5}}$ 3) $2^{\frac{2}{3}}$ 4) $\sqrt[4]{81}$

Teacher: Try Ismail mentioned that what you know of these numbers (Pointing $2^{\frac{2}{3}} = \sqrt{\quad}$), call a one!

Student/Ismail : (mention) 2 (two)

Teacher: (write down 2 at the $2^{\frac{2}{3}} = \sqrt{2}$), is called by Ismail

Teacher: (Designate Danial) mention one course

Student: (Danial mention), three sir!

Teacher: (write down 3 at the $\sqrt[3]{2}$)

Teacher: (Designate Sahra) mention, there still that need to written out? Appoint $2^{\frac{2}{3}} = \sqrt{2}$

Student: (Sahra paused and then mention) two !

Teacher: (write down 2 at the $\sqrt[3]{2^2}$)

Teacher: (Designate Sukmawati) Please you read, what reading this! (appoint $\sqrt[3]{2^2}$)

Student/Sukmawati : (mentions) three roots of two squared

Teacher: (Designate Fajar) Fajar could read? (appoint $\sqrt[3]{2^2}$)

Student / Fajar: (answer) forget sir!

Teacher: Well then, all the hear and look!

Teacher: This (pointing $\sqrt[3]{2^2}$) his reading, the cube root of two squared!

Teacher: This (pointing $\sqrt[5]{9^4}$) be parsed again!

Teacher: (writes = $\sqrt[5]{(3 \times 3)(3 \times 3)(3 \times 3)(3 \times 3)}$)

Teacher: Have a look here (pointing $\sqrt[5]{(3 \times 3)(3 \times 3)(3 \times 3)(3 \times 3)}$) all the, so that you understand!

Teacher: So the number 3 released one of (pointing $\sqrt[5]{(3 \times 3)(3 \times 3)(3 \times 3)(3 \times 3)}$) because pass one, whereas the rank 3 because his number was no escape as much 3

Teacher: Thus (write down 3 $\sqrt[5]{3^3}$) this is the simplest form

Student : From where 3 gained sir?

Teacher: Problem number 4 (write down $\sqrt[3]{81}$= $\sqrt[3]{(3x3x3x3)}$

Teacher: Why do not we outlined 9x9 ?, who knows?

Teacher: Because not immediately removed from the roots then we are outlined!

Teacher: Try (write down $\sqrt[3]{81} = \sqrt[3]{9x9}$), can be removed from its roots?

Student : No

Teacher: 81 = 9x9, 9x9 = 3x3x3x3

Teacher: So it $\sqrt[3]{81} = \sqrt[3]{3x3x3x3}$ (write down = 3 $\sqrt[3]{3}$)

Student : Sir, inquired Sir?

Teacher: Please

Student: If it's number 4 be a the rank fractional sir, such as the nature 2 described above, how to sir?

Teacher: explain by delivering some examples of different

The following stated structure thinking interaction teachers and students in the learning process of mathematics subject matter the rank fractional

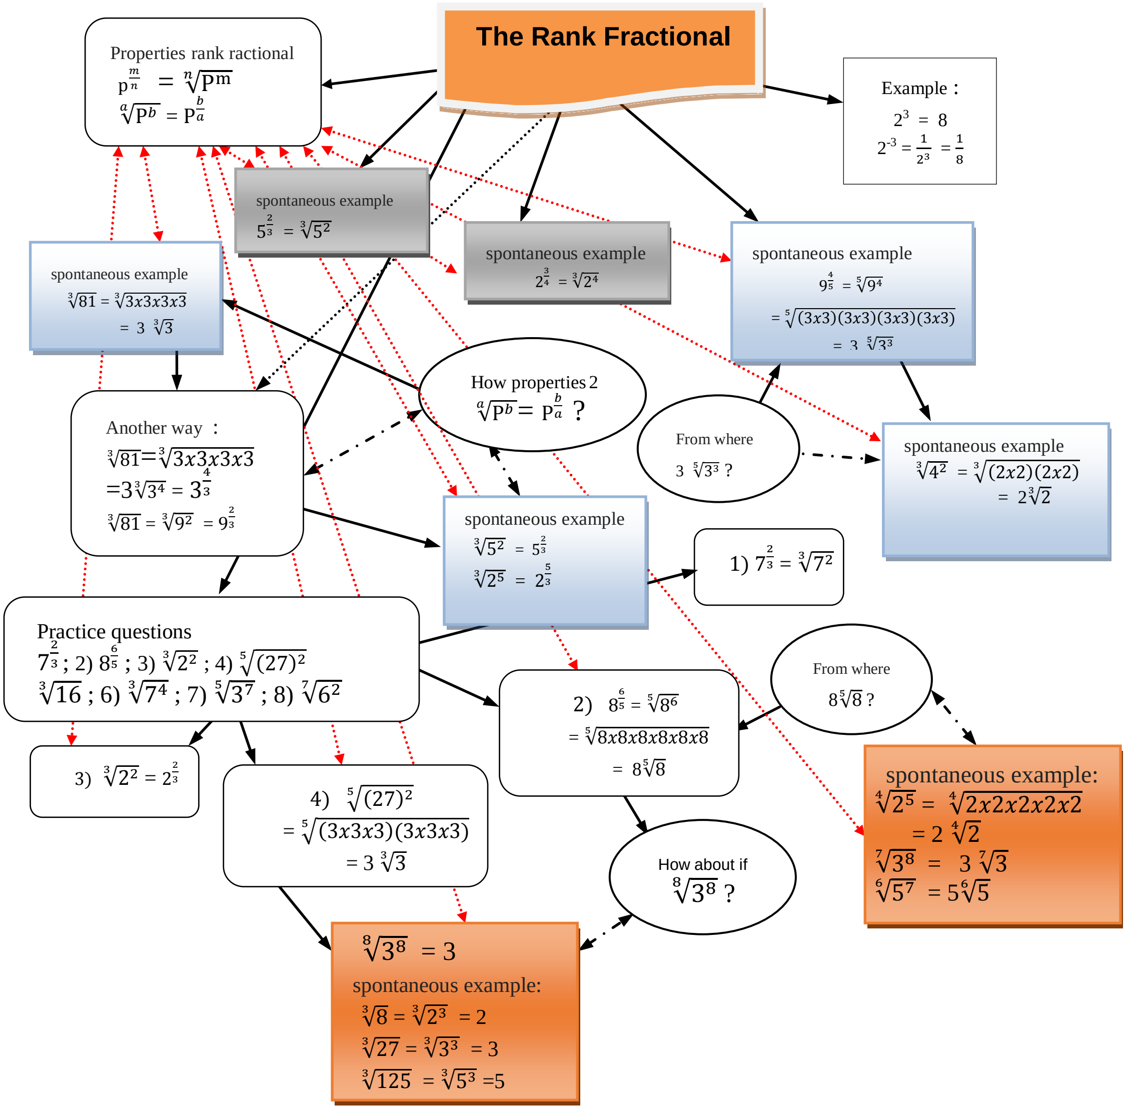

Diagram 2. Structure interaction thinking teacher and student in mathematics learning

Based on observations during the learning process in the classroom and diagram 2 above, teachers more often designate students to answer sample questions written by the teacher. Sometimes students who were not able to answer correctly because they trouble understanding the a concept the rank fraction. However, there are some students who are actively asking about the material identified by teachers. Students often different in mind with what was described by a teacher. So it felt not satisfied with the answers a teacher. This happens because the teacher did not explain in advance the meaning of the material being studied, but directly provide examples. And the examples are written not directly be explained, but it gives an opportunity (pointing) to the students to find the answers.

The thinking interaction between teachers and students at the time of the teacher gives some examples relating to the material the rank fraction. However, by the time teacher gives examples and then explain the example, sometimes students have of understanding or different ways, for example, when a teacher explain the examples do not like that is in the minds of students because answers from these examples do not like at the properties which force which has been described by previous teachers, so as to make students confused. Eg, the teacher gives an example $\sqrt[3]{81} = \sqrt[3]{3x3x3x3} = 3\sqrt[3]{3}$

In mind the student that ought answers some of these examples should be effective as of correspond to the the nature of or nature of powers of, or answers of the example its shape the rank fraction not cube root. Due to claim of one of his students, the teacher gives some examples the different. Spontaneous example such is an spontaneous example the illustrative its nature expansion of (expansive). Eg, the teacher wrote down another way, namely $\sqrt[3]{81} = \sqrt[3]{3x3x3x3} = 3\sqrt[3]{3} = 3^{4/3}$ Another possibility with writing down $\sqrt[3]{81} = \sqrt[3]{9^2} = 9^{2/3}$ (spontaneous example the illustrative that are simple). The teacher gives different example, namely $\sqrt[3]{5^2} = 5^{2/3}$ and $\sqrt[3]{2^5} = 2^{5/3}$. Then the teacher asked how to resolve if the cube root, cube root three were equal to the rank numbers is rooted, for example √ (8 & 3 ^ 8). Teachers give some examples the different based on the case raised by the student. Next, the teacher gives example spontaneous nature expansion of (expansive) as follows: a) $\sqrt[3]{8} = \sqrt[3]{2^3} = 2$, b) $\sqrt[3]{27} = \sqrt[3]{3^3} = 3$, and c) $\sqrt[3]{125} = \sqrt[3]{5^3} = 5$.

IV. DISCUSSION

In this study, 2 (two) characteristics spontaneous example in the learning process of mathematics. Two of these findings, namely klarifikatif and illustrative. However, in the presentation of illustrative appear spontaneous example in its nature: simple, equivalent, and expansion of (expansive). Clarification is spontaneous example settlement with classifies these examples, where teacher explains or review the completion of the sample. Illustrative is a spontaneous example by illustrating completion of these examples, where teacher explains and gives examples a different its nature is simple, equivalent, and expansion of (expansive). Spontaneous examples illustrative that its nature simple, the teacher gives some examples of more simple rather than previous example. Spontaneous examples illustrative its nature equivalent, the teacher gives several examples that equivalent the previous example. While the spontaneous examples its nature illustrative expansion, namely the teacher gives some example which is the expansion of some of previous example. In the presentation of the material the learning process mathematics in the classroom, teacher provide more spontaneous illustrative example. Examples given are examples that have arisen from the mind teacher spontaneously, then the teacher provides the spontaneous example illustrative its nature simple, equivalent, and expansion of (expansive).

Consideration teacher gives spontaneous example such, like example the rank fractions described above that begin with the rank positive or rank actual. Because it later when the they already know that 2^3 value is 8 then later on given 2^{-3} they will be confused, I say to the students that the rank of negative was converted into $^1/_?$. Then where the difference between 2^3 with 2^{-3} in integer with fractions. My commence not with the process, but the outcome, eg $2^{-2} = {}^1/_4$, $3^{-2} = {}^1/_9$. Similarly, that in presenting the examples I was begin with 2^3 instead of I began to 2^{-3}, possibly she was confused. Hence can be seen that the rank of positive outcome integers, but if the rank of negative numbers into fractions but there remains number 8. If I am developing further, eg 3^2 outcome 9, and 3^{-2} outcome $^1/_9$.

Use of many examples in the learning process is generally recognized to be important aspect and embedded most teaching mathematics (Atkinson et al, 2000; Bills et al, 2006; Carpenter, 1989; Mason, 2006; Stein et al, 1996; Zaslavsky, 2010; Zodik dan Zaslavsky, 2008). Examples are integral part of mathematical thought, learning and teaching, with particular regard to conceptualization, generalization, abstraction, argumentation and analogical thinking (Zodik dan Zaslavsky, 2008, hal. 165). Similarly, Bills et al (2006) argues that use of many examples inside have an impact of learning on the learner, ie have good reasoning and capability solving.

In the process of the thinking interaction in learning, according Vygotsky, there are two important principles in interactions (the thinking interaction), namely (1) regarding function and importance of language in social communication that begins the process of pencaderaan to sign until to exchange information and knowledge, and (2) Zone of Proximal Expansion (ZPD). Teachers as mediator has the role of and bridge the encourage students in their efforts build knowledge, understanding and competence. According the theory of Vygotsky, cognitive functions of humans derived from social interaction of each individual in a cultural context. Vygotsky also convinced that learning occurs moment students work handling tasks that have not be learnedhowever these tasks are still within range of capabilities namely the are within Zone of Proximal Expansion (ZPD) their. ZPD is the area between the actual expansion level which is defined as the ability solve problems independently with the level potential expansions were defined as problem solving skills under guidance of adults or their peers who are more capable.

V. Recommendation

In this research only limited to the certain areas of material, ie one subject (the rank fraction) in the field of algebra. It is therefore, as ingredients for expansion subsequent researchers were want to conduct research, relating to the thinking interaction of teachers and students in of spontaneous example learning of mathematics, should review or developing on the other subject matter on the field algebra or geometry fields.

An Analysis of Problems on Eight Grade of Mathematics Textbook Based on PISA's Framework

Budi Murtiyasa[1], Sri Rejeki[2], Sarlita Murdaningsih[3]
[1,2,3]Deparment of Mathematics Education, Universitas Muhammadiyah Surakarta
budi.murtiyasa@ums.ac.id

Abstract— One of the reasons of the implementation of new curricula is the low achievement of Indonesian student in international survey like PISA. To support the implementation of the new curricula, known as K-13, student's mathematics textbook was developed. The objective of research is to analyze suitability between the problems on eight grade of mathematics textbook and PISA's Framework as well as on content, process, and context. This study is descriptive qualitative research. The result of the research are that the contents of the textbook are in line with the PISA's framework although the 1st semester is dominated by change and relationship content, meanwhile the 2nd semester is dominated by space and shape content. The process in the textbook involve applying, reasoning, critical thinking, and problem solving. Meanwhile, the problems in the textbook are lack of scientific context. The problems are dominated by personal context.

Keywords: *critical thingking, mathematics literacy, mathematics textbook, PISA's Framework, and problem solving*

I. INTRODUCTION

In the manufacturing and agrarian economies that existed 50 years ago, it was enough to master reading, writing, and arithmetic. In the modern era, those competency aren't enough. According [1], If today's students want to compete in this global society, however, they must also be proficient communicators, creators, critical thinkers, and collaborators. On the other hand, in era information education must facilities to explore creativity, critical thinking, communications, and collaboration ('four Cs') for the students. Besides, the students also need additional competencies like language, arts, geography, sciences, and social studies. In the classroom, the teachers must be provides those additional skills in his teaching.

Focus to gives four Cs skills, mathematics teaching must elaborate aspects of creativity and innovation, critical thinking and problem solving, communication and collaboration [2]. Creativity and innovation aspect ask students use a wide range of techniques to create new and worthwhile ideas, elaborate, refine, analyze and evaluate their own ideas in order to improve and maximize creative efforts, and demonstrate originality and inventiveness, in both an individual as well as group settings. Meanwhile, critical thinking and problem solving aspects are intended students reason effectively, use systems thinking and understand how parts of a whole interact with each other. They make judgments, decisions and solve problems in both conventional and innovative ways. Moreover, communication and collaboration aspects meant students know how to articulate thoughts and ideas effectively using oral, written and nonverbal communication. They listen effectively to decipher meaning, such as knowledge, values, attitudes and intentions, and use communication for a wide range of purposes in diverse teams and environments. The three aspects of mathematics teaching be expected supporting mathematics literacy for the students.

According [3], mathematical literacy is an individual's capacity to formulate, employ, and interpret mathematics in a variety of contexts. It includes reasoning mathematically and using mathematical concepts, procedures, facts and tools to describe, explain and predict phenomena. It assists individuals to recognize the role that mathematics plays in the world and to make the well-founded judgments and decisions needed by constructive, engaged and reflective citizens. OECD organize survey every three year through Program for International Student Assesment (PISA) to understand mathematical literacy. PISA survey conducted since 2000 is assessment of 15-year-old students, which in Indonesia usually on eight grades. The achievement of Indonesia students on PISA Survey are very low. In 2000, Indonesia student are on rank 39th of 41 countries, in 2003 on rank 38th of 40 countries, in 2006 on rank 50th of 57 countries, in 2009 on rank 61st of 65 countries, and in 2012 on rank 64th of 65 countries.

PISA Survey indicates that mathematical literacy of Indonesian students is on low level. Its mean that Indonesian students lack of creativity, innovation, and reasoning to solve a mathematics problems which are usually presented in real world context. Problems on PISA assesses mathematical literacy on three aspect, i.e. process, content, and context. Moreover [3] explain that mathematical process include (a) formulating situations mathematically; (b) employing mathematical concepts, facts, procedures, and reasoning; and (c) interpreting, applying and evaluating mathematical outcomes. Mathematical content include change and relationship, quantity, space and shape, and uncertainty and data. Meanwhile mathematical context include personal, occupation, public, and scientific.

One of the effort of Indonesian government, i.e. ministry of education and culture to increase student's achievement in international survey like PISA is developing new curricula, known as K-13. In K-13, mathematics curricula had major change. Elements of change in mathematics subject include: (a) start from concrete problems, semi-abstract, then abstract problems, (b) formula derived by students and the problems must be solved using basic formula and understanding, (c) balance between number, graph, figure, and pattern, (d) designed for critical thinking, (e) familiarize with algorithmic thinking, (f) extend of content about probability, data analysis, and statistics, and (g) introduce approach and estimate concepts. In new curricula K-13, mathematics subject attempted to give four Cs skills and to support mathematical literacy.

Developing new curricula needs a new book for delivery the subject, both teacher and student textbook. The quality of mathematical textbook which is used the students influence the quality of teaching. According [4] who studied about suitability between mathematical textbook grade tens and syllabus of K-13, indicate that 80,49% content of textbook are suitability to basic competencies, 95,83% are suitability to scientific approach, and 88,80% are suitability to authentic assessment. Meanwhile [5] who studied about analysis of problems on ten grade mathematics textbook K-13 using PISA framework indicate that number of problems which suitability with PISA framework are 44 problems (46,81%).

Paper addresses an analysis of problems on eight grade mathematical textbook. Paper would be describing the problems on mathematical textbook on the aspects of process, content, and context. Analysis of problems on the textbook focus on the practice problems and competency test on every chapter of the textbook.

II. RESEARCH METHOD

This study is descriptive qualitative research. Object of the research is mathematics textbook both semester 1st and semester 2nd which are published by Ministry of Education and Culture [6], [7]. Data was collected using observation and interview. Observation method is to analyze a problems using PISA's framework. Moreover, problems are classified into process, content, and context categories. Method of interview is complement to know about implementation of mathematics textbook in teaching. Interview done to both teacher and students. Analysis of data using procedure data reduction, data display, and make a conclusion.

III. RESULT AND DISCUSSION

Eight grade mathematics textbook for 1st semester consist 6 chapters and it contain 246 problems. Meanwhile, on the 2nd semester consist 6 chapters and it contain 239 problems. Based on PISA Frameworks, generally on content aspect, problems on textbook cover all of content i.e change and relationships, space and shape, quantity, and uncertainty and data. In Table 1, from the aspect content, problems on mathematics textbook dominated by change and relationships. The textbook for 1st semester dominated by change and relationships content amount of 55,28%, and quantity content is only 5,06%. Meanwhile, mathematics textbook for 2nd semester dominated by space and shape content amount of 41,42%, and uncertainty and data content is only 15,48%. In average, eight grade mathematics textbook is dominated by change and relationship content amount 45,36%.

Table 1. Classification of Mathematics Problems based on Content

Content	Semester I	Semester II	Average
1. Change and relationship	55,28%	35,14%	45,36%
2. Space and shape	33,73%	41,42%	37,52%
3. Quantity	5,06%	18,41%	12,16%
4. Uncertainty and Data	10,56%	15,48%	12,98%

There are some a good problems PISA-like on eight grade mathematics textbook. For example, on the 1st Semester, practice 5.3, problem number 1 as follow.

'*Tinggi sebuah jendela lantai 2 pada sebuah gedung kira-kira 8 meter. Di depan gedung tersebut ada sebuah taman dengan lebar 6 meter. Berapa panjang tangga minimum yang dibutuhkan agar kaki-kaki tangga tidak merusak taman tersebut*?' (Height of the window on the

2nd floor of a building is about 8 meters. In the front of the building, there is a garden which have 6 meters in width. If someone want to reach the window using ladder, how many minimum length of the ladder so that foot of the ladder can't damage the garden?'

Content of the problem is space and shape. The problem associated to plane geometry, i.e. right triangle especially Pythagorean Theorem. The students be expected have capability to represent some object, i.e. ladder, walls, and the garden which are form like a right triangle. By using phytagorean theorem, the students be expected to solve the problem.

According the mathematical process, the problem above can be classified into employing mathematical concepts, facts, procedures, and reasoning. To solve the problems, the student must be able to: (a) make a design and implement the strategy to discover a solution, (b) apply a mathematical fact, rule, algorithm, and mathematical structure, (c) manipulate a number and represent a geometry, (d) explore of information and make mathematical construction, (e) use and switch among different representation of the object, and (f) make a generalization based on mathematical procedure to get a solution.

Table 2. Classification of Mathematics Problems based on Process

Process	Semester I	Semester II	Average
1. formulating situations mathematically	35,77%	17,57%	26,80%
2. employing mathematical concepts, facts, procedures, and reasoning	63,01%	69,45%	66,18%
3. interpreting, applying and evaluating mathematical outcomes	15,04%	22,17%	18,55%

Analysis of mathematical process, most of the problems on eight grade mathematics textbook focus on employing mathematical concepts, facts, procedures, and reasoning. On Table 2 can be observed that the process of employing mathematical concepts, facts, procedures, and reasoning both the 1st semester and 2nd semester are more dominant, i.e. amount of 63,01% and 69,45% respectively. Meanwhile the process of interpreting, applying and evaluating mathematical outcomes on the 1st semester is very low compare to the others process, that is 15,04%. Moreover, the process of formulating situations mathematically on the 2nd semester is only 17,57%. Generally, the mathematical process of employing mathematical concepts, facts, procedures, and reasoning is more dominant compare to the other process, i.e amount of 66,18%. The process in the textbook involve applying, reasoning, critical thinking, and problem solving.

Table 3. Classification of Mathematics Problems based on Context

Process	Semester I	Semester II	Average
1. personal	8,9%	26,35%	17,52%
2. occupation	4,87%	7,94%	6,39%
3. public	8,13%	5,02%	6,59%
4. scientific	2,43%	3,34%	2,88%

In mathematical context, the problems on eight grade mathematics textbook indicate that personal context is more dominant. Table 3 shows that both on the 1st semester and the 2nd semester personal context amount of 8,9% and 26,3% respectively. Conversely, the problems is lack on scientific context, on the 1st semester and the 2nd semester are 2,43% and 3,34% respectively. Generally, mathematical context dominated by personal context that is 17,52%. Although the personal context is dominant, some problems on occupation context began to introduce which is not limited in trading or marketing problems. For example, on the mathematics textbook 2nd semester, chapter 6 on competency test 6, problem number 14 as follow.

'*Kalian adalah manajer Timnas U-16. Suatu ketika Timnas bertanding di final fiala Asia melawan Malaysia. Suatu ketika saat pertandingan sedang berjalan, pada menit ke 89 Timnas mendapatkan hadiah penalty. Skor sementara adalag 2 – 2. Pemain yang siap menendang adalah Evan Dimas, Ilham, Maldini, dan Muchlis. Seandainya kalian disuruh menentukan penendang penalty tersebut, siapakah yang akan kalian tunjuk agar Timnas meraih kemenangan? Berikut catatan tendangan penalty keempat pemain tersebut*.

Name	Penalty (times)	Goal	block or caught by keeper	Out of the target
Evan Dimas	20	16	2	2
Ilham	18	14	2	2
Maldini	17	12	4	1
Muchlis	15	11	3	1

The problem above can be classified into occupational context, i.e. as manager of national team. Manager want to select the best player to take penalty kick so that the national team become the winner. Content of the problem above is uncertainty and data. In this case, data display about penalty kick of the players. The mathematical process of the problem above is about formulating situations mathematically. In this case, the students ask to identify mathematical aspects of the problems on real context world. Moreover, the student also ask to: identify a variables that associated to the problem, simply the situation or problem, represent the problem in different ways, organize the problem into mathematical concepts and make new assumption, and identify mathematical facts or procedure to solve the problem.

If the objective of the problems on mathematics textbook is to increase mathematical literacy, generally number of problems PISA-like are still need to be added. Table 4 shows that the problems on eight grade mathematical textbook are lack of the problems PISA-like, i.e amount of 24,39% and 42,47% on 1st semester and 2nd semester respectively. Averagely, the number of problems which PISA-like are amount of 33,4%. Consequently, the problems on eight grade mathematics textbook aren't supporting yet the students to gain PISA standard.

Table 4. Recapitulation of Mathematics Problems

Problems	Semester I	Semester II	Average
Mathematics problems with content, process, and context like PISA	24,39%	42,47%	33,40%

The research result is in line with [5] i.e. the problems PISA-like on ten grade mathematics textbook is less than the problems non PISA-like. Meanwhile, the problems PISA-like on eight grade mathematics textbook are amount of 33,4%. Therefore, the problems both on eight grade and ten grade mathematics textbook aren't supporting yet the students become mathematical literacy.

The students argue that the problems PISA-like are more difficult than the problem non PISA-like. Generally, the student have an error to understand about significance and instruction of the problems. This is similar [6], error to understand about task, instruction, key information of the problems lead to mistake to solve the problems. The problems PISA-like ask the students to make a reasoning. Contrary, the students usually unfamiliar with the problems PISA-like. According to the teacher, all of aspects on PISA frameworks are included on eight grade mathematics textbook. Observing on mathematics teaching, the teacher isn't giving yet the problems PISA-like. Meanwhile, the mathematics textbook for K-13 is an effort of Ministry of Education and Culture to improve quality of education, especially in mathematics subject. The involvement of Indonesia on PISA survey is part to observe the development of educational program [9].

IV. CONCLUSION

The result of research indicate that the problems on eight grade mathematics textbook consist of all of aspect of PISA Frameworks, i.e mathematical process, content, and context. Mathematical process include formulating situations mathematically; employing mathematical concepts, facts, procedures, and reasoning; and interpreting, applying and evaluating mathematical outcomes. Mathematical content include change and relationship, quantity, space and shape, and uncertainty and data. Meanwhile mathematical context include personal, occupation, public, and scientific. Averagely, the problems on eight grade mathematical textbook that in line with PISA Framework is still low. The process in the textbook involve applying, reasoning, critical thinking, and problem solving. The content of the problems on mathematics text book dominated by change and relationships. Meanwhile the context of the problems on the textbook dominated by personal context.

The Use of Problem Based Learning to Improve Higher Order Thinking Skills in Junior Secondary School

Dita Puspitawedana[1], Jailani[2]
[1]Dita Puspitawedana (Department of Mathematics Education, Yogyakarta State University)
[2]Jailani (Faculty of Mathematics and Natural Science, Yogyakarta State University)
[1]puspita23@gmail.com

Abstract— The purpose of this article is to describe enhancement of higher order thinking skills in mathematics instruction by using problem based learning model. Higher order thinking skills is the skills in resolving problems in new situations by using knowledge that include critical thinking, creative thinking, and problem solving skills. Indicators of critical thinking skills include the ability to analyze information, the ability hypothesize, and the ability to evaluate and reflect. Indicators of creative thinking skills include the ability to create new ideas, the ability to create new alternatives, and the ability to reflect. Indicators of problem solving skills include the ability to analyze, conceptual and procedural knowledge. Problem based learning is an instructional model that is centered on the student in the learning process where students are presented a variety of real problems or not structured to motivate students to learn and engage students in the greater understanding. The syntax use include present the problems, planning resolution of problems, implementation of planning, presentation, and evaluation.

Keywrds: *problem based learning, higher order thinking skills, mathematics instruction*

I. INTRODUCTION

A. Background

Mathematics is a universal science for underlies the development of modern technology, have an important role in a variety of disciplines, and promote the power of human. Putting mathematics as a subject can to understand, fun, and exciting of course is not easy. Fact in the field of mathematics lessons for students, especially Junior Secondary School is not subject demand because it is considered difficult and boring. Student difficulties in mathematics caused by several things such as the ability to think not yet high, the instruction less than innovative, so are students reluctant to higher think. Memorizing culture is still often done to make students' skills in thinking does not lead to higher order thinking skills. Then, in efforts to solve math problems, students have not been able to explore their thinking to be more critical and creative. Of course it is a high order thinking skills is required. [1]*Higher Order Thinking* a process to think critically and creatively, which in turn can be used by students in completing activities. To overcome some of these factors, we need a innovation in instruction and the willingness of students to change their of thinking to higher order think. Innovation in instruction can be applying with mathematical models of learning more than exciting, innovative, and make students more active in the learning process. Model of instruction is appropriate to the learning objectives to be achieved will make the learning process more fun. *Problem Based Learning* is a learning model can be encourages students to get involved in the learning process. Instruction with problem based learning usually begin with giving problems to the students, so the students can explore the provision of knowledge and develop it to obtain a solution. It certainly can affect the thinking of students in finding solutions to the real problems with the ability to think critically and creatively, so can be promote Higher Order Thinking Skills. [2] The application of the model PBL influences the ability to problem-solving skills. [3]The students can use the problem-solving skills to explore the problems and determine the next syntax. Based on this background shows that the high order thinking skills is important in mathematics, so in this article will discuss the use of Problem

Based Learning to improve Higher Order Thinking Skills in Junior Secondary School.

B. Problem formulation

1. How the use of problem based learning to improve higher order thinking skills?

C. Purpose

1. To describe enhancement of higher order thinking skills in mathematics instruction by using problem based learning model.

D. Benefits

The benefits of this article is to know the importance of high order thinking skills in mathematics instruction. Use of problem based learning models in an effort to improve high order thinking skills effectively in accordance with the existing theory study, so it can be used by teachers and researchers as a benchmark in reviewing the theory so as to assist in innovation instruction and research conducted.

II. KAJIAN TEORI

A. Problem Based Learning (PBL)

1. Definition of Problem Based Learning (PBL)

The learning model is an important element in the learning process, where the presence of a model of learning in the learning process becomes more meaningfully and objectives of the learning will be achieved as desired. [4] Problem based learning is an approach to learning that is characterized by flexibility and diversity that can be applied in various ways and in subjects and different discipline and in diverse contexts as well. Difference and diversity issues that would later be able to motivate the students to solve a problem. [5] The problem-based learning approach, in complex real problems used to motivate students in identifying and researching concepts and principles are needed in working through these problems. [7]Problem Based Learning is recognized as a progressive active learning and student-centered, where the problem of unstructured used as a starting point in the learning process. In addition PBL is an instructional model that is very good for developing critical thinking skills. [8] The problem-based learning is a student-centered approach ynag governing curriculum and learning activities using unstructured problems and problems in the real world. Based on the above definition dapaat some concluded that Problem Based Learning (PBL) is a student-centered learning in which the learning process of students presented a variety of real problems or not structured to motivate students to learn and engage students kepemahaman larger.

2. Characteristics of Problem-based Learning (PBL)

Problem-based learning is based on problem situations confusing and unclear can arouse the curiosity of students and engage students in the inquiry. [8] Characteristics of PBL into six covering the problem as early learning, authentic, investigation and problem solving, interdisciplinary perspective, small group collaboration, and the results and presentation. [6] Problem Based Learning in the curriculum mempuanyai some of the following characteristics: (1) a problem as the starting point of learning, (2) the problem is a real world problem that is unstructured, (3) problems as various perspectives, (4) problems as challenges of knowledge, attitudes and competencies students to identify learning needs and new places of learning, (5) give priority to self-directed learning, (6) utilize various sources of knowledge, use and evaluate information, (7) learning is collaborative, communicative and cooperative, (8) the development of the investigation and problem solving skills ssangat important in determining the solution of the existing problems, (9) the cover in PBL consists of synthesis and integration pemeblajaran, (10) the closure on the process of PBL include evaluation and review the experience of learners and the learning process. [4] Characteristics of PBL are (1) the complex, the fact that there is only one correct answer which is the focus of the organization for learning, (2) the students work in tims to resolve the problem, identify gaps to learn and to develop viable solutions ,

(3) students received new information although learning by myself, (4) the teacher acts as a facilitator, (5) the problem leads to the clinical development of problem-solving abilities. Based bebrapa these opinions can be summed up the characteristics of the model problem based learning includes (1) a real problem as tititk early learning, (2) students as a group seeking solutions to problems real realistic, (3) the problem must be meaningful and it can be a challenge for students to find something the new, (4) students acquire new information to learn on their own as well as from a variety of sources of knowledge, (5) the teacher as facilitator, (6) use of the time, information, amenities are there to get troubleshooting solutions, (7) the students predicted to produce products and present it.

3. Syntax of Problem Based Learning

The purpose of Problem Based Learning is acquiring skills and problem-solving process. [6] Syntax in problem solving is to perform (1) the initial analysis, (2) the development of learning issues, (3) iteration of independent and collaborative problem solving, (4) the integration of new knowledge. Furthermore, students can evaluate and present the solutions obtained. [8]Something similar there are six stages in the model problem based learning that is giving problems, make the stages of problem solving, discovery troubleshooting solutions, assessment of the results of problem solving, presenting the resulting solution, and evaluate. The two theories previously put forward stages in the learning model of problem-based learning begins with administration problems, as well as the opinion by [7] namely (1) the presentation of the problem, (2) planning problem solving, (3) to carry out planning, (4) peyajian issues, and (5) reflection and debriefing. Based on expert opinion can be said to be the stages of learning problems can help students in higher-level thinking. Step-by-step problem-based learning in accordance with efforts to increase higher order thinking skills, namely (1) Presentation of the problem, be used as a starting point for learning sehinggadapat lead students to think critically, (2) planning problem solving, (3) the settlement of the problem, (4) presented the results, and (5) evaluate.

4. Excess problem based learning

The learning model used in the classroom learning process will affect the achievement of learning objectives sertaprestasi student learning. problem based learning has several advantages including: (1) PBL can provide a solid understanding of the basic knowledge-factual and apply; (2) provide opportunities for the development of critical appraisal skills; (3) the environment encourages students to ask questions; and (4) PBL allows students to create their own learning, becoming the basis for professional behavior in the future. It is also stated by [8] that is associated with the real world, encouraging students to learn actively, encouraging the birth of a variety of approaches to learning in an interdisciplinary manner, giving students the opportunity to choose what and how to be learned, encourage the creation of collaborative learning, and improve the quality of education. Based on the opinion of the experts put forward a model of problem based learning is an instructional model that is appropriate in order to increase high-level thinking skills of students in mathematics. Model problem based learning where students focus on learning in the learning process of students presented a variety of real problems or not structured to motivate students to learn and engage students kepemahaman larger.

B. Higher Order Thinking Skills (HOTS)

1. Definisi dan Indikator Higher Order Thinking Skills (HOTS)

Thinking is the cognitive skills to acquire knowledge. The ability to think can be defined as the cognitive processes that segregated into concrete steps that are then used as a guideline thought. Results in cognitive thinking can be seen from the high-level thinking skills HOTS identified using cognitive taxonomy. [9] Cognitive taxonomies are organized schemes for classifying instructional learning targets into various levels of complexity. Furthermore [9]defines the Higher Order Thinking into three categories yanitu, (1) Reviews those that define higher-order thinking in terms of the transfer, (2) Reviews those that define it in terms of critical thinking, and (3) Reviews those that define it in terms of problem solving. In line with [10] A clear and comprehensive, definition of higher order thinking has the potential to help educators transcend the split between the sciences" problem solving "and the humanities'" critical thinking. ". [1] the higher order thinking skills (HOTS) is divided into two components, critical thinking and creative thinking. Based on the opinion of some experts, we can conclude that HOTS is an ability in resolving problems in new situations by using knowledge. Such capabilities are critical thinking, creativity and the ability pemaecahan problem which is an indicator of high-level thinking skills. The explanation of these three indicators as follows.

a. Critical Thinking

Critical thinking skills is one of the high-level thinking skills that requires students be conscientious and finish a problem or give an opinion. [10]critical thinking abilities are specific cognitive skills that are used when a students exhibits critical behavior". Also according to [11] critical thinking is "reasonable, reflective thinking that is focused on desiding what to believe or do". Furthermore, the proposed [9] which explains that "as many of our readers know, critical thinking focuses on thinking that is reflective and that is directed toward analyzing particular arguments, recognizing fallacies and biases, and reaching Conclusions based on evidence and sound judgment ". Meanwhile, according to [12] argues that "critical thinking is thinking that examines, relates, and evaluates all aspect of the situation or problem. It include gathering, organizing, remembering, and analyzing information. Critical thinking includes the ability to read with understanding and to identity and Necessary extraneous material ". Based on the opinion of several experts can be concluded that critical thinking is a process of reflective thinking to decide what is credible and conducted in accordance with the information accompanied by evidence and good judgment. Indicators of critical thinking is.

1) *Analyzing information*
Collecting and analyzing relevant information on the situation and problems

2) Examines
Decisive step will be carried out according to the analysis of the information and the existing problems.

3) *Reflection and evaluation*
Explain the relevance of existing information, make inferences based on information and good judgment.

2. *Creative thinking*

Similarly, critical thinking, part of HOTS the other is where the critical thinking skills required in this kekmampuan ability to develop problem solving solution and find new solutions to a problem. According to [7] creative thinking is another type of thinking is of interest to educators. This type of thinking is normally associated with cognitive skills and abilities for coming up with novel solutions to problem situations. [9] characteristics of critical thinking is grounded (reasonable), yield (productivity), nonevaluatif, and touch (reflective). [7]creative thinking that is original and reflective thinking and that produces a complex product. According to some opinions can be concluded that creative thinking is a thought process that is original by using the capabilities to menciptkaan new ideas more meaningful. Thus it can be arranged indicators creative thinking as follows.

a. Cogent /reasonable
Combining ideas and use them appropriately in solving a problem

b. Productivity
Make or elaborated new alternative to mrnyelesaiakan a problem.

c. Reflection
Explain the relevance of the steps used in solving problems with information and ideas.

3. Problem solving skills

Before defining the problem solving, the first is to understand what was the problem. [9] Students incur a problem when they want to reach a specific outcome or goal but does not automatically Recognize the proper path or solution to use to reach it. [12] Problem solving is the application of Several rules to a problem not encountered before by the learner. Problem solving does not usually begin with a clear statement of the problem; rather, most problems must be identified in the environment; then they must be defined and represented mentally . [13] there are several indicators that the mathematical problem solving abilities.

1) identify the elements that are known, were asked, and the adequacy of the required elements;
2) formulate a mathematical problem or to develop a mathematical model;
3) implement strategies to solve a variety of problems (similar and new problems) inside or outside of mathematics;
4) explain or interpret the results according the problem of origin;
5) make the conclusion.

Based on some of the above opinion can be concluded that the problem-solving ability is one upon ability to solve a problem by using knowledge. Thus it can be arranged indicator problem solving skills as follows.

1) Analyze (Analyzing)

Menganalasis issue aims to sisiwa can determine the point of the problem, and write it in the form of a symbol so it will be easier for students to determine the steps to be used for resolving the problem.

2) Knowledge koneptual

Conceptual knowledge to assist students in understanding the problems and finding information to create strategies / measures to be used. Conceptual knowledge related to the situation of the problem, the information relefant, mathematical concepts and nature of logic.

3) Knowledge of procedural

Procedural knowledge related to the ability sisiwa in demonstrating measures / strategies used in accordance with the mathematical concept or model that is used in accordance with the problems.

III. CONCLUSION /INFERENCE

Based on the above discussion, the conclusion that can be drawn menganai how the problem based learning can improve HOTS is to see steps PBL models in an effort to improve HOTS tailored to the characteristics, namely PBL.

1. Presentation of the problem as early learning
2. Planning troubleshooting
3. Application design problem solving
4. Presentation
5. Evaluation and debriefing.

Integrating Maratib Qira'ah Al-Qur'an and Marzano's Taxonomy to Provides Learning Objectives in Mathematics

Kusaeri[1] and Dwi Prasetyo Pribadi[2]
[1, 2]Department of Mathematics and Science Education, Islamic State University of Sunan Ampel Surabaya, Indonesia
E-mail: kusaeri@uinsby.ac.id

Abstract: This research is a development research, which aims to develop a new taxonomy theoretically by integrating *marâtib qirâ'ah al-Qur'an* and Marzano's taxonomy. This integration produces a concept about the classification of learning objectives which more comprehensive, including the description of integration result and the indication of learning achievement in all levels of integration result. In addition, this research provides examples of its application in formulating mathematics learning objectives. The research data were obtained from the result of literature study and interviewed to the expert of Arabic and Qur'an Education. Data were analyzed as a material to formulate the draft of integration result. The drafts were discussed with the expert of Qur'an Education and the lecturer of Mathematics Education in a sustainable manner to obtain a logical and accountable result. The results shows that the integration between *marâtib qirâ'ah al-Qur'an* and Marzano's taxonomy produces 5 new levels in the classification of learning objectives. These classifications include: 1) Retrieving knowledge (Integration of *talaffuẓ* and retrieval); 2) Comprehending knowledge (Integration of *tafahhum* and comprehension); 3) Analyzing knowledge (Integration of *tadabbur* and analysis); 4) Utilizing knowledge (Integration of *tafakkur* and knowledge utilization); and 5) System of self-control (Integration of *takhassyu*', metacognitive system, and self-system).

Keywords: *marâtib qirâ'ah al-Qur'an, Marzano's taxonomy, and learning objectives*.

I. INTRODUCTION

Mathematics learning is a very important thing in the world of education. The importance of mathematics learning can not be separated from the role of mathematics in all aspects of life. However, the world notes that the mathematics education in Indonesia is far from perfect. It is proven from the acquisition of Indonesia in TIMSS 2011 which showed that the mathematical ability of Indonesian students is at level 36 of the 48 participant countries. That achievement was even relatively worse in PISA 2012, which puts Indonesia on the 2nd lowest rank of the 65 sample countries, ie only one rank higher than Peru. Considering the importance of mathematics, and also a variety of problems that arise in mathematics education in Indonesia, arises a question how should mathematics learning in schools be organized so that mathematics can be mastered by students well?

Kamol & Ban Har [1] states that in order to improve students' learning in mathematics, it is necessary to understand the developmental mode of their thinking and reasoning. Learning is planned based on the needs and characteristics of students and directed to the changing of students' behavior according to the objectives will be achieved [2]. In addition, in order to support the implementation of mathematics learning in schools, it should be structured the concept of mathematics curriculum used clearly and in focused [3]. Thus, in order to make mathematics learning in school run well, the teacher must design a learning process with clear directions and learning objectives.

Considering the importance of learning objectives in mathematics learning, it is required the guidelines to formulate appropriate learning objectives for teachers. For this purpose, some experts have classified the learning objectives in a model called education taxonomy. One of education taxonomy that is often used is Bloom's Taxonomy.

Bloom's taxonomy divides the learning objectives into three aspects, namely cognitive, affective, and psychomotor. But in reality, the learning objective that is often highlighted by teacher is only cognitive aspect, while other aspects are not integrated in the learning, whereas in completing a task or problem, it is not only the cognitive aspect that plays a role.

Marzano & Kendall tried to answer the issues of Bloom's taxonomy by establishing a new model of taxonomy, i.e Marzano's Taxonomy. This taxonomy answered the limitations of Bloom's taxonomy. Marzano & Kendall developed a model of taxonomy that combines the wide range factors that affect on how students think [4]. Marzano's taxonomy model contains three mental system: self-system, metacognitive system, and cognitive systems. The fourth component of this model is domain of knowledge.

The self-system includes a network of beliefs and goals that are interconnected which is used to make decisions about the appropriateness of involvement in a task. The metacognitive system is responsible for making purposes related to new tasks and designing strategies to achieve goals that have been made. The cognitive system is responsible for processing information effectively for the completion of tasks. The cognitive system has four levels, namely retrieval, comprehension, analysis, and knowledge utilization. These three systems require domain of knowledge that will affect the success of students in facing every task. Simply, the model of Marzano's taxonomy is stages in thinking and learning that is begun with remember, comprehend, analyze, and utilize the knowledge gained by using prior knowledge.

Actually, the stages in Marzano's taxonomy had been taught by the Prophet Muhammad SAW in interacting with al-Qur'an. As said by Sahabah that "We do not pass without even one verse with the Prophet unless we read, memorize, understand, and implement it" [5].

The Prophet has pointed out how he had a complete interaction with al-Qur'an, start from pronouncing, memorizing, contemplating and also implementing al-Qur'an. Similarly, in teaching of al-Qur'an, the Prophet always prioritized aspects of memorizing, understanding, and implementation as mentioned in an *atsar* of Abu 'Abd al-Rahman al-Sulami. He said:

> حَدَّثَنَا مَنْ كَانَ يُقْرِئُنَا مِنْ أَصْحَابِ رَسُولِ اللَّهِ - صَلَّى اللَّهُ عَلَيْهِ وَسَلَّمَ -أَنَّهُمْ كَانُوا يَأْخُذُونَ مِنْ رَسُولِ اللَّهِ - صَلَّى اللَّهُ عَلَيْهِ وَسَلَّمَ - عَشْرَ آيَاتٍ, فَلاَ يَأْخُذُونَ فِي الْعَشْرِ الْأُخْرَى حَتَّى يَعْلَمُوا مَا فِي هَذِهِ مِنَ الْعِلْمِ وَالْعَمَلِ. قَالَ: فَيُعَلِّمُنَا الْعِلْمَ وَالْعَمَلَ [6].
>
> Had met me people who have read al-Qur'an at us from Sahabah of the Prophet Muhammad SAW, that if they learn ten verses from the Prophet, they did not continue the ten verses later until they know the knowledge and implementation. They said: We learn the knowledge and implementation all at once.

Fahmi Jiwanto Islam, a prominent Islamic education, has described the stages of the Prophet in interacting with al-Qur'an above into a theory called *Marâtib Qirâ'ah Al-Qur'an. Maratib qira'ah al-Qur'an* consists of six stages, namely *talaffuẓ* (pronunciation), *tafahhum* (understanding), *tadabbur* (contemplation), *tafakkur* (thinking), *takhassyu*'(heartssolemn), and *tanfîẓ* (implementation). These stages can not be separated from one another and these are a one whole unit to be able to study al-Qur'an perfectly.

Based on the description above, then the problem deserves to be studied more deeply by conducting research to formulate integration of *marâtib qirâ'ah al-Qur'an* and Marzano's taxonomy. This integration combines the concept *marâtib qirâ'ah al-Qur'an* with Marzano's taxonomy into one whole unit. From this integration, can be produced a new concept about the classification of learning objectives that is more comprehensive and can be used as a basis formulation of mathematics learning objectives.

II. RESEARCH METHOD

This research is a development research. Development research is a type of research carried out to develop, deepen, or expand knowledge (education) that already exist [7]. In this case, the researchers will develop a new taxonomy in theory by integrating *Marâtib Qirâ'ah Al-Qur'an* and Marzano's Taxonomy as a basis for formulating learning objectives.

Based on the focus of research, the research was carried out through several stages. *First*, translating the book of *marâtib qirâ'ah al-Qur'an* with the help of an expert in Arabic. Then proceed to do literature study about *marâtib qirâ'ah al-Qur'an* and Marzano's taxonomy. At this stage, the researchers also conducted interviews to the expert of Arabic and Qur'an Education regarding *marâtib qirâ'ah al-Qur'an* and its relevance to Marzano's taxonomy.

Second, developing by combining the concept of *marâtib qirâ'ah al-Qur'an* with Marzano's taxonomy based on the data that has been collected. This stage produces an early research product in draft integration result of *marâtib qirâ'ah al-Qur'an* with Marzano's taxonomy. Then, the draft was discussed with expert of Qur'an Education and the lecturer of Mathematics Education in a sustainable manner to obtain a logical result and answerable.

Third, making a conclusion based on the results of discussions with the experts. At this stage, the researchers developed the concept of integration of *marâtib qirâ'ah al-Qur'an* with Marzano's taxonomy overall, including the description of integration result and the indication of learning achievement in all levels of integration result. In addition, it's also provided the examples of its application in formulating mathematics learning objectives.

In this research, data were collected by using refer to note technique and interviews. Refer to note technique is a technique of data collection by using books, literature or library materials, then note or citing expert opinion that is in the book [8]. Then, the collected data was analyzed by inductively, annotated bibliography, and content analysis. This was done to be able to find the key points of each stage in *marâtib qirâ'ah al-Qur'an* and Marzano's taxonomy. The results of this analysis were used to compose the draft of integration result which consists of definition and goals to be achieved at each stage in *marâtib qirâ'ah al-Qur'an*, Marzano's taxonomy, and the results of integration of both.

III. RESULT AND DISCUSSION

Marâtib qirâ'ah al-Qur'an is the stages of studying al-Qur'an carried out by a Muslim in order that al-Qur'an can be studied as a whole. This theory reviews the stages of studying al-Qur'an. In theory, there are six stages in the review of al-Qur'an. The definition of each stages can be seen in Table 1.

TABLE1. THE DEFINITION OF EACH STAGES IN MARÂTIB QIRÂ'AH AL-QUR'AN

Stages	Definition
1. *Talaffuẓ* (Pronunciation)	Reading al-Qur'an in accordance with the correct pronunciation, performed, and pronounced correctly.
2. *Tafahhum* (Understanding)	Understanding the meaning of the verses of al-Qur'an literally and its content.
3. *Tadabbur* (Contemplation)	Thinking by using the entire intellectual and logical questions to reach a new understanding, which is contained in the texts of al-Qur'an in accordance with the rules of the Arabic language, both connecting between sentences in al-Qur'an and letters in al-Qur'an.
4. *Tafakkur* (Thinking)	Thorough exploration process by contrasting from the meaning of *qauliyyah* verses (text of al-Qur'an) towards reading and analyzing of *kauniyyah* verses (universe) to generate some rules or lessons as a solution to a problem.
5. *Takhassyu'* (Solemn Heart)	Solemn mood as an effect received from the process of *talaffuẓ*, *tafahhum*, *tadabbur*, and *tafakkur* the verses of al-Qur'an.
6. *Tanfiẓ* (Implementation)	Conceiving and realizing the teachings of al-Qur'an in the life whole-heartedly in all aspects of life.

Marzano's taxonomy is a taxonomy of learning objectives to systematically define the variety of skills related to thinking and learning. Marzano's taxonomy reviews a process of student learning and thinking. This taxonomy is organized into 6 levels. The definition of each level in Marzano's taxonomy can be seen in Table 2 below.

TABLE 2. THE DEFINITION OF EACH LEVEL IN MARZANO'S TAXONOMY

Levels	Definition
1. Retrieval	A process of recalling already known knowledge, without necessarily understanding what he/she knows about it.
2. Comprehension	A process of organizing or managing existing knowledge, synthesizing representation (the ability of collecting the same components to form a new thought patterns), the steps are still rudimentary in understanding the basic or initial concept.
3. Analysis	A process of reaching and testing the suitability of knowledge of both the similarities and differences, analyzing the relationships upwards and downwards, classifying, analyzing errors, generalizing, specifying or for a logical consequence or the principle that can forma conclusion.
4. Knowledge utilization	A process of utilizing knowledge which could be a reference or solution, decision making, a question of

Levels	Definition
	experiment and can solve an application related to knowledge.
5. Metacognitive system	A process of monitoring and managing the various objectives of already understood knowledge and maintaining the level of achievement of these goals.
6. Self-system	A process of identifying emotional response, examining perception and self-motivation, testing self-benefit, deciding whether to continue daily habits or choose to reflect into a new activity.

Both of those theories above have relevance one another; reviewing someone's stages in learning. Based on that relevance, can be formed an integration that combines the concept of *marâtib qirâ'ah al-Qur'an* with Marzano's taxonomy into wholy unified concept. This integration produces new concept about the classification of learning objectives that more comprehensive, and can be used as a basis formulation of mathematics learning objectives. Briefly, this integration can be seen in Table 3.

TABLE 3. THE INTEGRATION OF MARÂTIB QIRÂ'AH AL-QUR'AN AND MARZANO'S TAXONOMY

Marâtib Qirâ'ah Al-Qur'an	**Marzano's Taxonomy**	**The Result of Integration**	
		Levels	**Definition**
Talaffuẓ	*Retrieval*	1. Retrieving knowledge (Integration of *talaffuẓ* and retrieval)	A process of remembering, recognizing, and executing already known knowledge correctly.
Tafahhum	*Comprehension*	2. Comprehending knowledge (Integration of *tafahhum* and comprehension)	A process of understanding, symbolizing, identifying and categorizing new knowledge as a basic understanding.
Tadabbur	*Analysis*	3. Analyzing knowledge (Integration of *tadabbur* and analysis)	A process of thinking about a meaning of knowledge in depth, which is carried out by comparing, classifying, concluding (specifying or generalizing), and analyzing errors the knowledge to generate new knowledge.
Tafakkur	*Knowledge utilization*	4. Utilizing knowledge (Integration of *tafakkur* and knowledge utilization)	A process of utilizing already known knowledge and juxtaposing with existing natural signs or phenomena as a basis for investigation, experimentation, problem solving, and decision making of a problem related to the knowledge.
Takhassyu'	*Metacognitive system*	5. System of self-control (Integration of *takhassyu'*, metacognitive system, and self-system)	A system involving self or heart to reach a deeper meaning of already owned knowledge, which is carried out by reflecting a thinking process that has been mastered by students and identifying an emotional response, motivation, and self-benefit of a new task faced by students.
	Self-system		

The levels of integration results are described below.

A. *Retrieving knowledge (Integration of talaffuẓ and retrieval)*

The first level, retrieving knowledge, was formed by integrating *talaffuẓ* and retrieval. Both of these (*talaffuẓ* and retrieval) have a slice each other, the *talaffuẓ* process goes on by using students' memories about *hijaiyah* letter (how to read and reading rules) in recognizing the verses of al-Qur'an were pronounced, how they should read these verses with correct recitation rule. This is similar to the processing knowledge goes on at retrieval level. Based on that slice, it is formed a new definition for level 1 of the integration result.

In the definition, it is obvious that the section taken from *talaffuẓ* is "implementing knowledge correctly". Reading, performed and pronounced in *talaffuẓ* are merged into one process, executing. While the section taken from retrieval is "recalling already known knowledge". In the retrieval, it is also followed by a process of recognizing and executing already known knowledge correctly. It is suitable with the description of the goals to be achieved in the retrieval level.

Retrieving knowledge is the lowest thinking process in a learning taken by students. When the students face a task in the learning process, they are only required to be able to remember, recognize, or execute the knowledge possessed to complete the task.

In the process of remembering knowledge, the indications that arise are: students can remember, mention, enunciate, pronounce (a name, word, or term), utter, give examples, list, label, and describe (who, what, where, when) based on the information that has been saved. In the process of recognizing knowledge, the indications of achievement are: students can recognize, select and identify from a list, and determine the truth of a statement. While in the process of implementing knowledge, the indications of achievement are: students can practice, demonstrate, show, equip, and chart based on the knowledge possessed.

Here are examples of mathematics learning objectives and their instrument about fraction at 7th grade that are formulated based on the indications of learning achievement at levels 1.

TABLE 4. THE MATHEMATICS LEARNING OBJECTIVES AND THEIR INSTRUMENT
BASED ON THE INDICATIONSOF LEARNING ACHIEVEMENT AT LEVEL 1

Learning Objectives	Instruments
1. Given a fractional number, students can identify the parts of these fractional number.	1. In fractional number $\frac{2}{5}$, which one as the denominator?
2. Students can calculate a multiplication result of any fractional number with integer.	2. What is the result of$18 \times \frac{1}{9}$?

B. Comprehending knowledge (Integration of tafahhum and comprehension)

Comprehending knowledge was formed by integrating *tafahhum* and comprehension. *Tafahhum* is a process to understand the verses of al-Qur'an literally and their content based on the books of *tafsir al-Qur'an*. This means that it is just as a basic understanding of the verses of al-Qur'an. As well as the comprehension, this process is carried out only to understand the basic or initial concept of knowledge. This is the slice of *tafahhum* with comprehension. Based on the slice, then it is formed a new definition for level 2 of the integration result.

In the definition, it is obvious that the section taken from *tafahum* is "understanding new knowledge as a basic understanding". Understanding the meaning literally in *tafahhum* is an analogy to a basic understanding of knowledge. While the section taken from comprehension is "symbolizing, identifying, and categorizing new knowledge as a basic understanding."

Comprehending knowledge is a level 2 thinking process in a learning taken by students. When the students face a task or a problem in the learning process, they are required to be able to understand the knowledge, symbolize it in the form of graphs, diagrams, symbols, or charts, identify the essential elements of knowledge, and put the essential elements in the appropriate category to solve the problem.

In the process of understanding knowledge, the indications of achievement are: students can describe, explain, and elucidate the meaning of certain facts or concepts in knowledge. In the process of symbolizing knowledge, the indications that arise are: students can symbolize, depict, represent, illustrate, draw, visualize, create a graph, create a chart, and create a model of the knowledge possessed.

The next is a process of identifying knowledge. The indications in this process are: students can describe the core part, describe how or why, and paraphrase (reiterating a fact or concept in another form to explain its meaning) the knowledge possessed. While the indications in the process of categorizing knowledge are: students can make a connections between, describe a relationship between, and summarize the knowledge possessed.

Here are examples of mathematics learning objectives and their instrument that are formulated based on the indication of learning achievement at level 2.

TABLE 5. THE MATHEMATICS LEARNING OBJECTIVES AND THEIR INSTRUMENT
BASED ON THE INDICATIONS OF LEARNING ACHIEVEMENT AT LEVEL 2

Learning Objectives	Instruments
1. Students can explain the meaning of fractional number in their own words.	1. Explain the meaning of fractional number in their own words!
2. Students can illustrate elements of problem in an image.	2. Ahmad follow a bike racing. During the race, the road is very slippery. After cycled as far as$\frac{1}{4}$ of the track, Ahmad fall. Then he goes racing back. But after taking two-thirds of the track, he fall again and can not continue the race because the bike was badly damaged. Describe in an image Ahmad's race track in accordance with the situation?

C. Analyzing knowledge (Integration of tadabbur and analysis)

Analyzing knowledge is the integration result between *tadabbur* and analysis. Both processes have each slice. *Tadabbur* is carried out to uncover the overall verses of al-Qur'an, to understand those verses in depth. As well as analysis, this process is carried out to analyze the knowledge possessed overall. Both processes seek to generate new insights and knowledge based on the knowledge possessed.

In the definition of analyzing knowledge, it is obvious that the section taken from *tadabbur* is "thinking about a meaning of knowledge in depth to generate new knowledge". This thinking process is carried out by analyzing texts, reasoning, generalizing thematically, analogizing, associating, *ta'wil*/interpreting, and concluding. While, the section taken from analysis is not quite different with the various processes in *tadabbur*, that is "a process of comparing, classifying, concluding (specifying or generalizing), and analyzing errors of the knowledge to generate new knowledge".

Analyzing knowledge is the level 3 thinking process in a learning taken by students. In this level, students are required to be able to compare, classify, analyze errors, and conclude knowledge, both specify and generalize, to generate new knowledge.

In the process of comparing knowledge, the indications of achievement are: students can associate, compare, differentiate, contrast, analogize with certain knowledge, sort, and categorize various knowledge that has been owned by the students. In the process of classifying knowledge, the indications achievement are: students can identify different kind of knowledge, classify, organize, arrange the knowledge, and identify the broader category.

The next is the process of concluding knowledge, which consists of generalizing and specifying. In the process of generalizing, the indications of achievement are: students can make a certain rule, generalization, or principle; generalize; and conclude based on some specific information. Whereas, the indications of achievement in the process of specification are: students can interpret or *ta'wil* (interpret the implicit meaning) a problem; develop and sustain the argument; and conclude, predict or decide something that will happen.

The latter process is analyzing errors. The indications of achievement in this process are: students can identify a problem, issue, misunderstanding; analyze and diagnose a fault in a certain topic; judge, criticize, and fix it to get a logical and accurate knowledge.

Here are examples of mathematics learning objectives and their instrument that are formulated based on the indication of learning achievement at level 3.

TABLE 6. THE MATHEMATICS LEARNING OBJECTIVES AND THEIR INSTRUMENT BASED ON THE INDICATIONS OF LEARNING ACHIEVEMENT AT LEVEL 3

Learning Objectives	**Instruments**
1. Students can explain the reason why $\frac{a}{b} \div \frac{c}{d}$ is equal to $\frac{a}{b} \times \frac{d}{c}$, which a, b, c, and d are natural numbers.	1. Explain the reason why the division of $\frac{2}{3} \div \frac{11}{12}$ can be written as $\frac{2}{3} \times \frac{12}{11}$!
2. Given few decimal number, students can identify the numbers that can be converted into fractions.	2. Which of the following numbers that can be converted into fractions? a. 3,141592 ... c. 2,1232323 ... b. 0,717273 ... d. 1,987189 ...

D. *Utilizing knowledge(Integration of tafakkur with knowledge utilization)*

Utilizing knowledge is the integration result between *tafakkur* and knowledge utilization. Both of these have a slice each other, which *tafakkur* process is carried out by starting from the meaning of *qauliyyah* verses (text of al-Qur'an) to the reading and analyzing *kauniyyah* verses (universe) to generate a solution of a problem. As well as knowledge utilization, which is the process of utilizing knowledge that become a reference in solving problems related to knowledge. It shows that in both of these processes, students attempted to use their knowledge to solve a problem related to the knowledge.

In the definition of the level 4 integration results, it is obvious that the section taken from *tafakkur* is "utilizing already known knowledge and juxtaposing with existing natural signs or phenomena". This is carried out to generate a solution of a problem. While the section taken from knowledge utilization is "utilizing already known knowledge as a basis for investigation, experimentation, problem solving, and decision making of a problem related to the knowledge".

Utilizing knowledge is a level 4 thinking process in a learning taken by students. In this level, students are required to conduct an investigation, experimentation, problem solving, and decision making of a problem by utilizing already known knowledge and juxtaposing with existing natural signs or phenomena.

In the process of conducting an investigation, the indications of student achievement are: students can investigate why and how something can happen, examine the characteristics of something that has been defined, and investigate what would happen if certain treatment or condition is given. In the process of conducting an experiment, the indications of achievement are: students can generate and test hypotheses, test produced ideas, predict what will happen, and determine an explanation of certain theory.

Then, in the process of problem solving, the indications of achievement are: students can resolve and overcome problems associated with the knowledge, find a strategy to solve problems, or develop a way to achieve a goal under certain conditions. While in the decision making process, the indications of achievement are: students may take a decision, consider and choose the best way to achieve a goal based on some options.

Here are examples of mathematics learning objectives and their instrument that are formulated based on the indication of learning achievement at level 4.

TABLE 7. THE MATHEMATICS LEARNING OBJECTIVES AND THEIR INSTRUMENT
BASED ON THE INDICATIONS OF LEARNING ACHIEVEMENT AT LEVEL 4

Learning Objectives	**Instruments**
1. Students can solve a problem related to fractions and tenancy law in real life.	1. Harits has made *ijarah* (tenancy) agreement of Avanza car for homecoming with the deal price of Rp 5,850,000 within a month. After, it's used for 10 days, the car was damaged and Harits decided to cancel the agreement. If the general price within 10 days (the period after using a car) worth Rp 2,500,000 and the general price within 20 days (the period before using a car) worth Rp 4,000,000. So,how much cost of the rent should be paid by Harits for 10 days?
2. Students can develop a strategy to solve a problem related to fractions and inheritance law.	2. Once, there was a father who died and left three sons. He wrote a testament that his heritage in the form of goats was divided by division as follows: - The first son got half $\left(\frac{1}{2}\right)$, - The second son got $\left(\frac{1}{3}\right)$, and - The youngest son got $\left(\frac{1}{9}\right)$. Well, then a problem arose because the number of goats are 17 goats. With simple math, the eldest son should gets $8\frac{1}{2}$goats, the second son gets $5\frac{2}{3}$ goats, and the youngest son will gets $1\frac{8}{9}$ goats. However, they wanted the goats alive. If they divide the goats in that way, there would be few goats to be slaughtered. So, how was the way to divide the goats? Can you help them?

E. System of self-control (Integration of takhassyu', metacognitive system, and self-system)

System of self-control was formed by integrating among *takhassyu*', metacognitive system and self-system. These three processes have slice to one another, that is the involvement of heart, self, or affective side of students in carrying out these three processes. *Takhassyu*' is a process of gaining the deeper meaning of knowledge that has been processed in the previous stages by using heart solemn. As well as metacognitive system and self-system. In both of these systems, students have been involved their affective side in undergoing a learning process, so that they are able to reflect the learning process that they have been mastered, recognize and develop themselves [9].

Additionally, Suryanti [10] states that according to al-Ghazali, *khussyu*' includes six things, namely the presence of heart (*hudhurul qalb*), understanding between the read and done (*tafahhum*), glorifying Allah SWT (*ta'ẓim*), feeling daunted towards Allah SWT (*haibah*), feeling full of hope to Allah SWT (*raja'*), and feeling ashamed to Him (*haya'*). One part of *khussyu*', namely "*tafahhum*" which can be interpreted as conscious or understand, has relevance to the meaning of metacognitive. Metacognitive can be defined as the awareness of thinking process. In this case, metacognitive system is responsible to monitor the thinking process of students in order to operate properly.

While another part of *khussyu*', the "*hudhurul qalb*" which means the presence of heart or self, has relevance to the self-system. The relevance is clearly seen in the self-system,that the system also involve the self in the acquisition of knowledge and thinking processes that had been owned by students. "*Raja*'" or feeling full of hope to Allah SWT, may also be related with the self-system. The feeling full of hope related with self-motivation which is organized in the self-system. These further relevances strengthen the integration among *takhassyu*', metacognitive system and the self-system.

Based on these relevances, then formed a new definition of the level 5 integration result, as set out in Table 3. In the definition of level 5, it is obvious that the section from *takhassyu*' is "a system involving self or heart to reach a deeper meaning of already owned knowledge". It is obvious, because *takhassyu*' is a process that is carried out after the process of *talaffuẓ*, *tafahhum*, *tadabbur*, and *tafakkur* verses of al-Qur'an. The section taken from the metacognitive system is "a system involving self, which is reflecting a thinking process that has been mastered by students". It refers to the ability to set objectives to be achieved in a task and maintain the level of achievement in these objectives. The section taken from the self-system is "a system involving self, which is identifying an emotional response, motivation, and self-benefit of a new task faced by students".

The system of self-control occupies in level 5 or the last level in a learning taken by students. This system is not a process that has a direct indication. This system only supports the implementation of thinking process and exist inside the self or heart of person. The sign for the success of this system is the success that was also achieved in the thinking process at other levels.

IV. CONCLUSION

Based on the results of research on integration of *Marâtib Qirâ'ah al-Qur'an* and Marzano's Taxonomy and its application in the mathematics learning, then obtained some conclusions as follows. Integration of *marâtib qirâ'ah al-Qur'an* and Marzano's taxonomy produce 5 new levels in the classification of learning objectives that is more comprehensive. Five level, namely: 1) Retrieving knowledge (Integration of *talaffuẓ* with retrieval); 2) Comprehending knowledge (Integration of *tafahhum* with comprehension); 3) Analyzing knowledge (Integration of *tadabbur* with analysis); 4) Utilizing knowledge (Integration of *tafakkur* with knowledge utilization); and 5) System of self-control (Integration of *takhassyu*', metacognitive system, and self-system).

Indications of learning achievement at any level of the integration results refer to the processes at any level as follows. Retrieving knowledge consists of a process of remembering, recognizing, and executing knowledge. Comprehending knowledge consists of a process of understanding, symbolizing, identifying, and categorizing knowledge. Analyzing knowledge consists of a process of comparing, classifying, analyzing errors, and concluding knowledge, both specifying and generalizing. Utilizing knowledge consists of a process of investigation, experimentation, problem solving, and decision making. System of self-control has no direct indication.

***Abstract*—**The aim of this research was to describe the probabilistic thinking of elementary school students in solving contextual and non contextual probability tasks. The subject was a student of fifth grade and a communicative boy. The triangulation of data of subject was used in difference time. The data analysis was categorizing, reducing, explaining, interpreting and concluding data. The result showed that in non contextual probability tasks, he could determine all possible outcomes in one-dimensional but failed in two-dimensional sample space. He failed in event and comparison probability tasks. He thought all events had opportunity to occur. However, in contextual probability tasks, he determined all possible outcomes in one- and two-dimensional sample space by using *odometer* strategy. Meanwhile, he used *numerator* strategy in solving probability event task to examine the part that corresponds to the event. In solving comparison probability task, he thought that a situation would give much more opportunity for target event, if it had a little bit sample space than other situation. This result was important for curriculum developer to introduce probability to elementary school students by probability contextual tasks related to their childhood.

Keywords:*Probabilistic Thinking, Elementary School Students, Contextual Probability Task, Non Contextual Probability Task*

I. INTRODUCTION

Advances in science and technology can not be separated from the human mind. A lot of scientists who have done some experiments as result of his thinking in develop science and technology and can be useful for humans in implementing for their survival. It is clear that the scientists just do not do the deterministic thinking in his job, but they also need to do probabilistic thinking. Because probabilistic thinking can provide a rational framework for making inferences and test hypotheses based on uncertainempirical data. For example, a scientist states that the drug has been produced, 99% could increase the child's appetite, after doing some research in the laboratory.

The example above show that the scientists provide conclusions related to events that will occur at the drug was produced by stating that the drug has been produced 99% could increase the child's appetite. 99% shows the degree of confidence of scientists to the drugs that has been produced. This confidence level appears based on the probabilistic thinking. Itmeans that scientist has estimated the success of the drug to the increase child's appetite with a notice things, so that it appears as a measure of the quantity estimation results.

One of the concepts to study the quantity of the magnitude of the degree of confidence is the probability. Further,[1]stated that the probability was the study of likelihood and uncertainty. It played a critical role in all of the professions and in most everyday decisions.[2]stated that the probability was the mathematical way to deal with problems of uncertainty. It was a tool for measuring the appearance chance of events. [3]explainsed that the probability was an old mathematical discipline dealing with calculating the probability of various events.[4]suggested that the probability of any event was expressed as a ratio of the number of potential outcomes that may be Considered successful over the number of all possible outcomes, successful plus unsuccessful. This was in line with the opinion of[5] which stated that the probability was an assigned value (actually an estimate) given to the likelihood of a particular outcome occurring in a random situation. It was calculated by forming a part-whole fraction; the numerator being the number of times an outcome can occur and the denominator being the total number of possible outcomes. While [6]stated that the probabilistic thinking was a mode of reasoning is attempting to quantify uncertainty, as a tool for decision making. In the study [7]the term probabilistic thinking would be used to describe children's thinking in response to any probability situation. Further [8]stated that a probabilistic reasoning implied to reason under uncertainty. This reasoning took in consideration two important components: the variability of the result and randomness. Thus there is a relationship between probabilistic thinking and probability. If probabilistic thinking is the mental activity of a person in response to a situation which contains an element of uncertainty, then the probability is the branch of mathematics that studies the issues that contain elements of uncertainty.

Based on probabilistic thinking and probability explanation, then in an effort to develop probabilistic thinking of students as a preparation to face the science and technology, needs to be done by introducing the material probability to students in primary school. [9]suggested that the probability need to be introduced to students ranging from elementary level, as the foundation of students to study the probability at higher levels.

Lately a lot of researches related to probabilistic thinking of elementary students in response probability tasks. [3]had done research on low-grade students were kindergartens and elementary schools to differentiate among certain, possible and impossible events, and compare the probability of various events. The result of this study was students coulddifferentiate between three events. Further [10]in his study of 404 students in 2^{th} to 6^{th} grade with instruments related to differentiate among certain, possible and impossible events, and compare the probability of various events, determine events most likely to occur, determine the two boxes of the most may produce white or black ball. The results of this study concluded that the majority of students could recognize different events and categorized them based on the probability. Two results of this study stated that elementary students succeed in responding to the standard probability tasks (non-contextual).

In addition, [11] in his study of 29 students aged 14 to 16 years. Types of tasks provided are (1) advertising involving sex of a baby, (2) black and white marble problem, and (3) red and blue marble problem Box A and Box B. Two of the first task were a context task. The analysis was based on four categories of response is non response, non statistical response, partial statistical response and statistical response. The results of this research focused on non statistical response, that wasmany students used strategies based on the experience of culture (beliefs, everyday experience and school) and intuitive strategy. This was in line with the results of the study [12]of the fifth grade elementary school students low math skill in response probability tasks. The subject gave non statistical response that students gave reasons which refered to everyday experience. Student's responded that if Ivan selected the meatball, then he selected tea ice, lemon ice and coconut ice. But when the student answered that Ivan selected a soup, then he selected tea ice and lemon ice while coconutice is impossible. When researcher askedhis reason, the subject replied that the soup did not match with coconut ice. As well as if Ivan selected chicken noodle, then Ivan selectedtea ice and lemon ice. While coconut ice was not suitable for chicken noodle. When the researcher asked why did not match?, subject replied that according to him was not delicious if after eating chicken noodles, drinking coconut ice. This response showed the subjectivity of student is influenced by everyday experience.

Based on the explanations that have been presented, then there are differences of probabilistic thinking of elementary school students in solving contextual and non-contextual probability tasks. This difference becomes the focus of researcher to explore probabilistic thinking of elementary students in solving contextual and non contextual probability tasks. Aspects of probabilistic thinking can be seen from the responses and strategies are used by students in solving probability tasks. [11]developed the four categories of student's responses are non response, non statistical response, partial statistical response and statistical response. The tasks related with list or identify the complete set of possible outcomes in one-dimensional and two-dimensional, [13]in his study stated that there are six strategies could be used by children in completing tasks bear dressed with tops and pants. The strategies were solution strategy A (random selection of items with no rejection of inappropriate items), solution strategy B (trial and error procedure with random item selection and rejection of inappropriate items), solution strategy C (emerging pattern in item selestion, with rejection of inappropriate items), solution strategy D (consistent and complete cyclical pattern in item selection, with rejection of inappropriate items), solution strategy E (emergence of an "odometer" pattern in item selection, with possible item rejection), solution strategy F (complete odometer pattern in the selection of items, with no rejection of items). Furthermore, [14]in his study of 9-year-old students with high ability and low ability, described how the student could construct mathematical ideas for solving problems. When students lack of formal knowledge, they relied on informal model of the problem situation by using a strategy to produce a solution. And there were three strategies used by students in solving a problem, that are non planing, transitional and odometer. And then elaborated again by [15]into 5 strategies were trial and error strategy, emerging strategy, a cyclic pattern strategy, odometer with errors strategy, odometer strategy. The task related with identify and justify which of two or three events are most likely or least likely to occur, [16]stated that there were three strategies used by students in completing the task of this probability, namely (a) a numerator strategy in the which they only examine the part of the set that corresponds to the target of the event, (b) an incomplete denominator strategy in the which they examine the part that corresponds to the complement of the event, and (c) an integrating strategy in the which they relate the number of the target elements with the total number of elements in the set. Further, The task relate with determine and justify: (a) which probability situation is more likely to generate the target event in a random draw, [16]identified three strategies used by students, namely (a) set with more target event, (b) set with less non target event, and (c) set with the greater difference in favor of the target event.

In addition to the response and strategy aspects, there is other aspect that relate to probabilistic thinking is representation. The representation is the result of a person's mental activity that can be seen by naked eye. In connection with the representation of students in solving probability tasks, [7] found that students used the language of an invention or a conventional language to described the part-whole. Meaning of the language of the present invention that one or more students suggested their different ways in describing probability. This language was used either verbally or in writing. As an example of the invention is the use of language "one of three" to described the probability rather than used a conventional language was one-third. And one of the results of research [17]stated that students pay attention of whole with whole description of the spinner with 100% representation. Model area and description of 50% and the phrase "half"were seen familiar to two students at the initial interview.

Based on the explanations that have been presented, the study aims to describe probabilistic thinking of elementary school students in solving contextual and non contextual probability tasks. So the results of this study can provide benefits, especially for curriculum developers to introduce probability to Elementary School by designing an approach or strategy that can accommodate aspects of probabilsitic thinking of students. In addition, the results of this study can complement theories that already exist on probabilistic thinking especially for elementary school students.

II. METHOD

This study will describe probabilistic thinking of elementary school students in solving contextual and non contextual probability tasks. The research reveals a natural phenomenon (naturalistic) of the subject when solving probability tasks and the main instrument is the researcher. Therefore, this type of research is exploratory research, whereas this is a qualitative research approach.

A. *Subject*

Research's subject is a 5th grade student of elementary school with certain criteria, the boy who has high math skill and able to communicate fluently. The reason to choose boy student because according to research [18]boys had scored higher than girls on probabilistic reasoning, while the results of [19]showed that boy have fewer misconceptions than girl. While the selection of students with high math skill because research [20]stated that students with high math skill were able to respond to probability tasks by using a specific strategy and representation.

B. *Instrument*

The main instrument in this study was researcher. And supporting instruments, namely (a) the instrument of mathematical ability of students, (b) instrument probability tasks, and (c) the instrument guided interview. Each contextual and non contextual probability tasks contained about: (1) the sample space was related to identify the complete set of outcomes in a one and two-dimension problem, (2) the probability of an event was related to identify and justify which of event are most likely to occur, and (3) the probability comparison was related to determine and justifywhich probability situation is more likely to generate the target event in a random draw.

C. *Prosedure*

Collecting data in this study was done 2 times, namely the collection of data on probabilistic thinking of elementary school students in solving contextual probability task and non contextual probability task. 1) In non contextual task, the data collection process was begun with the provision of instrument probability task to the research's subject. Subject did probability task according to his ability and write his answer according to what he think. Researcher recorded the subject's behavior (expression), including the unique of the subject when solving probability tasks. Furthermore, researcher interviewed subject related to the aspects about probabilistic thinking. Triangulation of the interview data in this study useddifferent time triangulation, that was comparing and checking data or information from the result of completion probability task without experimentation with different time. 2) After all of the data collection process related to probabilistic thinking of elementary school students in solving non contextual probability task was complete, the process of collecting data to describe probabilistic thinking of elementary school students in solving contextual probability tasks was begun by giving instrument of contextual probability to the research's subject. Researcher recorded the subject's behavior (expression), including the unique things of the subject when solving probability tasks through experiments. Furthermore, researcher interview subject related to aspects the probabilistic thinking. Triangulation of the interview data in this study used triangulation time.

D. Analysis

The process of data analysis in this study consist of:

1. Categorization/Data Classification
   Categorization in this study was defined as the process of selecting and grouping of data that had the same meaning when it was associated with aspects of probabilistic thinking of elementary students.
2. Data Reduction
   Reduction of data in this study was defined as the process of data reduction, that was less unnecessary and irrelevant.
3. Presentation of Data
   Presentation of data in this study was defined as the process of writing the data was already categorized, further examination of the data to determine the consistency of the information was given by subject in order to obtain credible research data (data triangulation).
4. Interpretation of Data
   Interpretation of the data in this study was defined as a process of understanding the meaning of a set of data that had been presented. Furthermore, the discussion and comparing data from credible research with the literature and the particular theory.
5. Conclusion
   Conclusions in this study was defined as the process of formulating the meaning of research of result based on discussions of the data collected. This conclusion meant to described probabilistic thinking of elementary school students in solving contextual and non contextual probability tasks.

III. RESULT

A. Probabilistic Thinking of Elementary School Student in Solving Non Contextual Probability Task

1. Sample Space

A statistical response was given by subject in solving task to identify what color of the ball could be drawn from a box which containing 4 red balls, 3 blue balls and 2 green balls. The subject could determine outcomes in drawn of ball. The strategy was used by the subject showed no trial and error strategy because the subject was not answer the question by trial and error, but the subject gave a reason. The reason of subject is that because ball was randomly drawn from the box. This could be seen in the following interview transcript.

PLTT1N112: What is your answer?
SLTT1N112: It can be red, blue and green
PLTT1N113: The reason?
SLTT1N113: Because in the box, is randomized then taken
PLTT1N114: What does it mean randomized then taken?
SLTT1N114: Because in the box they were randomized and thenit's taken, you can receive red, blue or green colours

Representation was used by the subject in this issue by list all thepossible outcomes.

However, in the sampel space two dimension task he failed to identify a couple of number and color in spinner, when two spinners were playing together. Subject mentioned that the results may be designated by the arrow was the number 1, 2, and blue, yellow, red, green and purple. It could be seen from the transcript of the interview follows.

PLTT1N210: What is your answer?
SLTT1N210: The numbers can be 1 and 2, colors are blue, yellow, red, green, purple
PLTT1N211: The reason?

SLTT1N211: Because when spinner is rotated, it can get number 1 and number 2, and the color blue, yellow, red, green, purple
PLTT1N212: So, it means how many pairs of numberand color that can be designated by the arrow?
SLTT1N212: Seven, here is 5 (pointing spinner color) and 2 ishere (pointing spinner number)
PLTT1N213: What are the seven?
SLTT1N213: Blue, yellow, red, green, purple, 1, and 2

Based on the transcript of the interview above, indicated that the subject did not pair numbers and colors on the spinner.

2. *Probability of an Event*

Subject failed to determine what was most likely of the ball was picked up from a box containing 4 red balls, 3 blue balls and 2 green balls. The subject replied that most probably drawn ball was a ball of red, blue and green. Subject thought that the three colors of the balls had the same chance.

The subject also failed to determine which were most likely to appear,dice more than 3or less than 3 of throwing the dice. Students thought that by throwing dice, a person did not know how many dice that would appear, dice more than 3and less than 3had a same chance to emerge. The transcript of the interview can be seen follow.

PLTT1N315: What is your reason, why are the most likely to appear on the dice that could be more than 3 or less than 3?
SLTT1N315: Because when inflated can be get more than 3 and less than 3
PLTT1N316: How can they are the most likelythe to appear?
SLTT1N316: When inflated can be more than three or less than three
PLTT1N317: What does it mean how can be more than three, less than 3? Why?
SLTT1N317: Yes possibility
PLTT1N318: What is mean of possibility?
SLTT1N318: If inflated upward, typically more than three or less than three
PLTT1N319: Your mean, you do not know will get which?
SLTT1N319: Yes
PLTT1N320: Why did not know?
SLTT1N320: Because when inflated get many numbers

3. *ProbabilityComparison*

The subject also failed to determine where the boxes were most likely to get the black marker, if there were two boxes, the first box contains 3 blue markers and 2 black markers and the second box contains 4 blue markers and 3 black markers. The transcript of the interview can be seen follow.

PLTT1N408: If you want to get a black marker, where the box should you take out?
SLTT1N408: Box I and II
PLTT1N409: Why are I and II boxes?
SLTT1N409: Because box I and II contains a black marker

Based on the transcript of the interview above, indicatesd that the subject could not compare boxes were most likely to produce a black markers in decision markers. Subject thought that the two boxes together contain black marker, so that in taking one of the markers in the box, I and II boxes produce black color markers.

The subject also failed to determine of the spinner which most likely refers to the red color, if there were two different spinners. The transcript of the interview can be seen follow.

PLTT1N505: What spinner should give most likely to the red color?
SLTT1N505: My answer, could spinner A and B
PLTT1N506: How can be spinner A and B?
SLTT1N506: Because when I rotated can get the red color also
PLTT1N508: But if you're asked to choose, what will you choose?The A or B?
SLTT1N508: A and B,Miss
PLTT1N510: The reason?
SLTT1N510: Because when I rotated I can get the red color also
PLTT1N511: How can it get red color, in the A and B?
SLTT1N511: Because when it's rotated it can get the red color also
PLTT1N512: Yeah why you choose both can get the red color?

SLTT1N512: Because in the two spinner, there are red

Based on the transcript of the interview above, indicated that the subject could not compare the spinner which were most likely to produce a red color. In fact, when the researcher asked the subject to choose one spinner, subject still chose A and B. The subject's reason indicated that the subject thought that on both of spinner equally there were red, so that both spinner gave the opportunity to appoint the color red.

B. Probabilistic Thinking of Elementary School Student in Solving Non Contextual Probability Task

1. Sample Space

The statistical respon was given by student to choose one food and one drink that could be ordered by Dinda, since the subject could list all the probably outcomes. The most efficient strategy, namely the strategy odometer was used by subject. This was because the subject chose one food as a constant item which was paired with 3 different drinks to get all couples of food and drink. Representations were written by the subject can be seen in Figure 2.1.

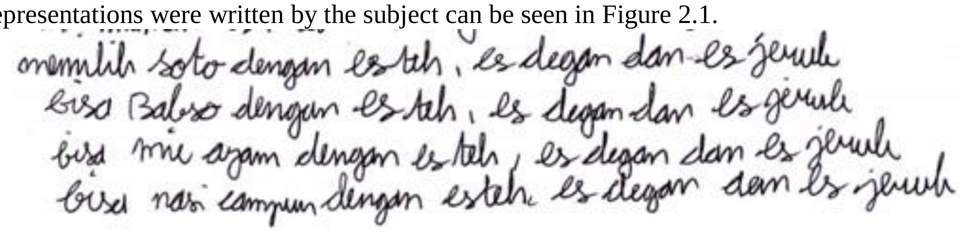

FIGURE 1. Representation of Subjects in Solving 2 Dimensions Sample Space Task

2. Probability of an Event

Partial statistical response was given by subject in solving the probability of an event task. This was because the subject's reason refered to the proportionality misconception, that was the subject chose colors on the spinner which hadnumbers more than others. The transcript of the interview can be seen follow.

PLTT1N706: What color will you choose in order to win this game?
SLTT1N706: I will choose blue, Mam
PLTT1N707: Why do you choose the blue?
SLTT1N707: Because in this spinner mostly blue
PLTT1N708: How many blue?
SLTT1N708: There are 2
PLTT1N709: yellow?
SLTT1N709: 1
PLTT1N710: The Green?
SLTT1N710: 1
PLTT1N711: Do all colors have same size?
SLTT1N711: Same

Based on the interview above, showed that subject used a numerator strategy, because the subject checked the size of each color on the spinner. And colors with the larger size was the color most likely designated by arrows.

3. ProbabilityComparison

Partial statistical response was given by subject in solving comparison statistical of probability task. This was because the subject's reason refered to the proportionality misconception, that was the subject selected a coin because had two sample space, and a dice with many 6 sample space. The transcript of the interview can be seen follow.

PLTT1N808: You're one of the players, do you want to choose to use a coin or use dice?
SLTT1N808: Coin
PLTT1N809: Why do you choose a coin?
SLTT1N809: Because there are 2 pictures
PLTT1N810: What about the dice?
SLTT1N810: There are many pictures, Miss, there are 6
PLTT1N811: But why if the pictures are 2and the other is 6, you will choose the one which has 2 pictures?

SLTT1N811: It can get the number 500 easily
PLTT1N812: What about the dice?
SLTT1N812: To get the number 3 and 5 is difficult
PLTT1N813: Why difficult?
SLTT1N813: Because there are the numbers 1 to 6

IV. DISCUSSION

Overall, students had failed to respond non contextual probability tasks. It appeared that the students failed to respond a couple of numbers and colors when two spinners were rotated, and the students also failed to choose which color ball was most likely to be drawn from the box and which figure was most likely to appear on the tossed of the dice. Students also failed to select box and spinner which were most likely to get a target event. The failure of these students is because students thought that all events had the opportunity to occur.

However, the contextual probability task, student was able to respond to tasks using a variety of strategies and representations. In two-dimensional sample space, student gave statistical response because he could list all possible outcomes with odometer strategy. And students gave partial statistical response on probability of an event. The student's reason refered to proportionality misconception. The numerator strategy was used by students to examine the part of the set that corresponds to the target of the event. In comparison probability task, a partial statistical response was used by student. The student's reason refered to proportionality misconception. Student chose a coin to play. This was because the coin had space samples less than dice, so it more likely had a great chance to win. Itmeans student thought that a situation would give much more opportunity for the target event, if it had a fewer sample space than other situation.

Based on the responses of students in solving contextual and non contextual probability tasks, obviously there are differences. Student is more successful in solving contextual probability tasks. Because, student understand the purpose of the questions easier. In addition, student will think based on his experience in daily life so that student are able to respond and use strategies in solving problems. This is in accordance with the opinion of [14]and [21]which stated that the task of the probability associated with contextual would be easier for students to respond to the task of probabilities, because the task could bring students in everyday life, so that students were able to respond to the task though using their own strategy. However, such a strategy could be redeveloped into a formal mathematical rules. It is important to teach probability for elementary school students, it means the probability can be introduced to elementary school students by probability contextual tasks related to their childhood, such as games etc.

V. CONCLUSION

In non contextual probability tasks, student could determine all possible outcomes in one-dimensional but failed in two-dimensional sample space. Student failed in probability events and comparison probability tasks. Student thought that all events have the opportunity to occur. However, in the contextual probability tasks, student determined all possible outcomes in one- and two-dimensional sample space by using odometer strategy. Meanwhile, student used numerator strategy in solving probability event task to examine the part that corresponds to the event. In solving comparison probability task, student thought that a situation would give much more opportunity for the target event, if it had a little bit sample space than other situation. This result is important for curriculum developers to introduce probability to elementary school students by contextual probability tasks related to their childhood. The result can be used as input for the elementary mathematics curriculum developers to be able to introduce probability in primary level by associating the student's childhood, such as games. Furthermore, the result can be used as input for teachers and other researchers associated with the strategy and approach that must be done to introduce probability for elementary students. In addition, for other researchers need to examine more deeply about probabilistic thinking of elementary school students views of other aspects, so that the study of the probabilistic thinking of elementary school students will be more complete and perfect.

ACKNOWLEDGMENT

Acknowledgements I give to ICRIEMS UNY organizer 2016 which has provided an opportunity for me to convey results of my research for the sake of improving the quality of education, especially math education.

Students' competence Development on Learning Fractal Geometry by Experiments Using ICT Tool

Dwi Juniati, I Ketut Budayasa
Department of Mathematics, Universitas Negeri Surabaya (UNESA)
dwi_juniati@yahoo.com

Abstract—The new curriculum of high education based on competence of graduates. The competencies that students should develop are comprehending the knowledge and use it to solve the problems by explorative and experiments activities and using appropriate ICT tools. One of the subjects of mathematics that students learn is Fractal Geometry. Geometry is one of the oldest mathematics sciences that never stop to be studied and be developed. The newest geometry that brings us some new perspective is Fractal Geometry. Fractal Geometry based on study about how look like a continuous function that is not differentiable everywhere and this subject brings us to new concepts of dimension that can be a positive rational number. When we study about fractal geometry, one of importances things is how can we develop some fractal objects. One method that can be used to create fractal objects are Lindenmayer system. In order to develop competencies of students, the lecture emphasised the experiments task and used ICT tools to help the students to create some fractal objects. This paper will present how experiment activities using ICT tool helped students to create fractal objects by Lindenmayer system.
Keywords: *sudents'competence, Fractal Geometry, learning by experiments, ICT Tool.*

I. INTRODUCTION

The new curriculum of high education is based on the competence of graduates. The competences that students should develop are comprehending the knowledge and use it to solve the problems by explorative and experiments activities and using appropriate ICT tools. Experiments in mathematics here is an approach using an ICT tool to investigate fractal objects and identify properties and its patterns. With these experiments, the students generate and confirm or confront their conjectures so that they can understand more about the subject they learn than just a theory and can develop some strategies to solve the problems. By using ICT tools, they can discover some new patterns and make a relation and construct some conjectures and testing their conjecture easily. The ICT tools or computer program that are used in this research is open accsess and students are asked to choose the appropriate tool.

The term "fractal" was first used by French-America mathematician, Benoît Mandelbrot in 1975. Mandelbrot based it on the Latin, frāctus meaning "broken" or "fractured", and used it to extend the concept of theoretical fractional dimensions to geometric patterns in nature. A fractal is a mathematical set that has a fractal dimension that usually exceeds its topological dimension and may fall between the integers. Fractals are typically self-similar patterns, where self-similar means they are "the same from near as from far" and exactly the same at every scale.

One method that can be used to create fractal objects is Lindenmayer system or is called by L-systems. Lindenmayer systems were introduced by Aristid Lindenmayer as mathematical formalism for modeling multi cellular organisms that form linear or branching filaments. The basic idea of this system is forming complex objects by successively replacing parts of a simple initial object using a set rewriting rules or productions, usually is done recursively. L-systems are parallel rewriting systems operating on strings of symbols. Lindenmayer system is formed by initial state or axiom, a set of symbols contain production rules. Many fractals can also be thought of as sequences of line segments, depends on the lengths of the line segments and the angles between the line segments.

Example of a Lindenmayer system:
Axiom : -F
Rule : F=F+F-F-F+F (means that we replace F with F+F-F-F+F)
Angle : 90 °
The product of this system are:
n=0, -F
n=1, -F+F-F-F+F
n=2, - F+F-F-F+F + F+F-F-F+F - F+F-F-F+F - F+F-F-F+F + F+F-F-F+F
and so on.

To produce fractal objects, the string generated by Lindenmayer system must contain the necessary information about geometry figure. One interpretation of a string is turtle graphic which translate symbol or string to geometric forms. Geometric Interpretation of the symbols or string are:
F : means move forward one step.
+ : turn left by angle θ
- : turn right by angle θ (is equal 90° if is not determined)
By geometric interpretation above, for n=1 , -F+F-F-F+F we have :

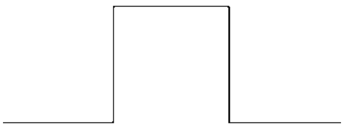

FIGURE 1. FIGURE FOR N=1

And for n=2, - F+F-F-F+F + F+F-F-F+F - F+F-F-F+F - F+F-F-F+F + F+F-F-F+F , here we replace every representation of F by the form of n=1, and the form is below:

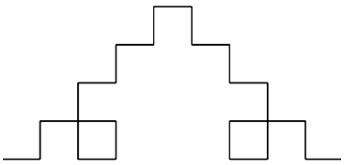

FIGURE 2. FIGURE FOR N=2

If the process continue recursively, for n=5, we have this form:

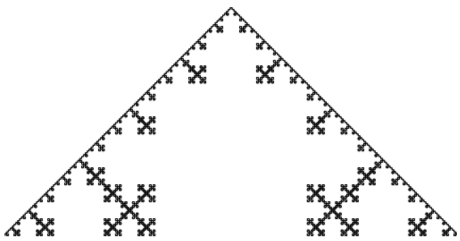

FIGURE 3. FIGURE FOR N=5

II. LEARNING FRACTAL BY EXPERIMENT ACTIVITIES USING ICT TOOL

A. Aim of the research

The aim of this research were to describe how the experiments activities using ICT tool helped the students to develop their competencies to constructs fractal objects and found the relations between the rule of the Lindenmayer system, the angle and its geometric interpretations.

The aims of learning geometry fractal by Lindenmayer systems by experiments are:
(i). The students understand about this system and know how to use this system to create an fractal object.
(ii). The students develop some strategies by experiments when construct a system for some object that are given.
(iii). The students realize the relations between length of line segment, the angle and the object.

B. Subject and method

The subjects of this research were Universitas Negeri Surabaya undergraduate students of fractal geometry class, consisting of 20 students.
To know about the role of the experiments activities using ICT tool in Fractal learning, at first the students were asked to do the tasks without experiments using ICT tools, after several time they worked for the same tasks with experiments using ICT tool that they chose.
The works with and without experiments activities were analyzed and compared.

C. The tasks

The tasks are given to students to construct fractal object by Lindenmayer system were four tasks.
TASK 1
Give the geometric interpretation for n=1 to n=3 of the following Lindenmayer system.
Axiom : F
Rule : F=F+F- - F+F
Angle : 60°.

TASK 2
Given the following image of a phytagorean tree and find the Lindenmayer system for this image.

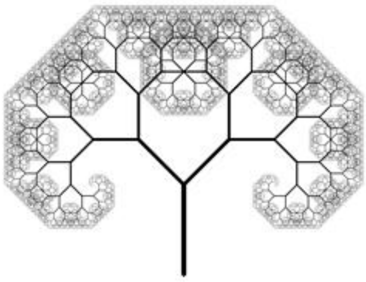

FIGURE 4. FIGURE OF PHYTAGOREAN TREE

TASK 3
Contruct a Lindenmayer system of marigolds leaves (in bahasa: daun kenikir) in which the image is given the following. Describe your strategies to form letter “S” for the stem leaf.

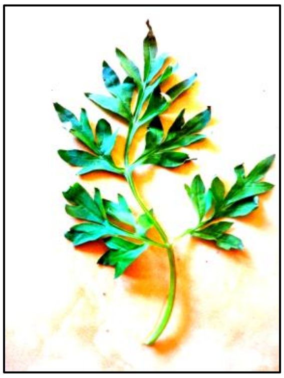

FIGURE 5. FIGURE OF MARIGOLDS LEAVES

ISBN 978-602-74529-0-9

TASK 4
Find an object in your neighborhood, take a photo of this object and construct the Lindenmayer system of this object and give the geometry interpretations of your system.

D. Results

In this section, we describe the works of students with and without experiments using ICT tool.
TASK 1.
There was no different results before and after experiments activities. Almost all students gave the same image, before the experiments they did the interpretation of the given system using ruler and protractor to measure the angle, and after experiments using ICT tool they found the similar shape, looked like the following image:

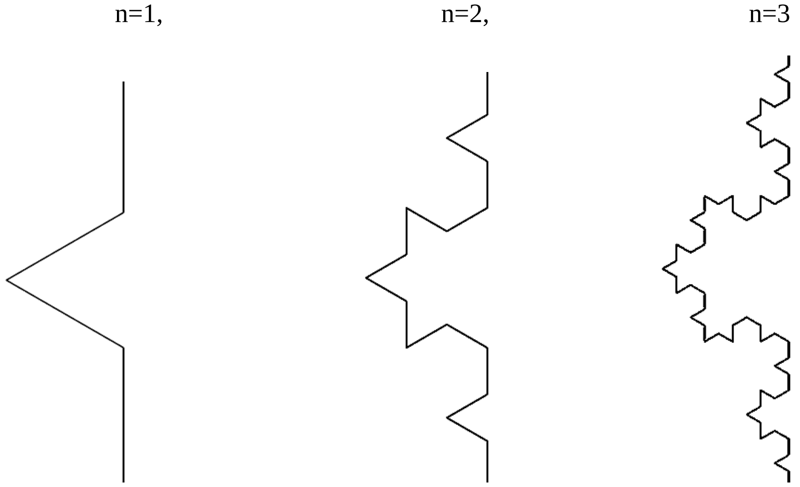

FIGURE 6. GEOMETRIC INTERPRETATION OF THE SYSTEM

TASK 2
Using ruler and protractor, the students measured the lenght and the angle between line segment and the create the system of this Phytagorean tree. The strategies that they used are focus on the stem of the tree and characterized the repeated pattern.
The system that they found without experment did not respect to accuracy of line segment ratio. Here, the Lindenmayer system and geometric interpretation of almost all students,
Axiom : XF
Rule : F=F[+F][-F]
Angle : 45°.
The geometric interpresentation for n=1, 2, 3 and 5.

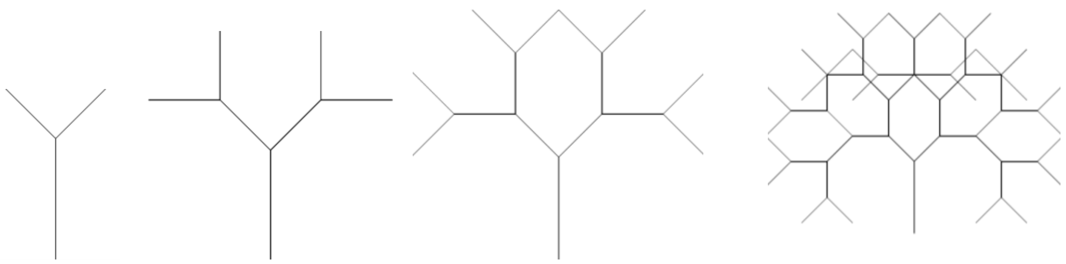

FIGURE 7. PHYTAGOREAN TREE WITHOUT EXPERIMENT

When they used ICT tool to experiment with, they could change the system and saw the changement they made about the ratio of the line segment and rechanged again and again to get the better geometric image.

TASK 3

Before experiments activities, 75% of students said that it is impossible to construct Lindenmayer system for the stem leave with the form "S" shape using line and the angle., and the rest of them said they did not know how to make a "S" shape. The system were created did not product "S" shape for the stem leaves.

The Lindenmayer system :
Axiom : X
Rules : X=F[+X][-X]FX;
F=FF
Sudut : 27^o and the following interpretation for n=1 to 3 respectively.

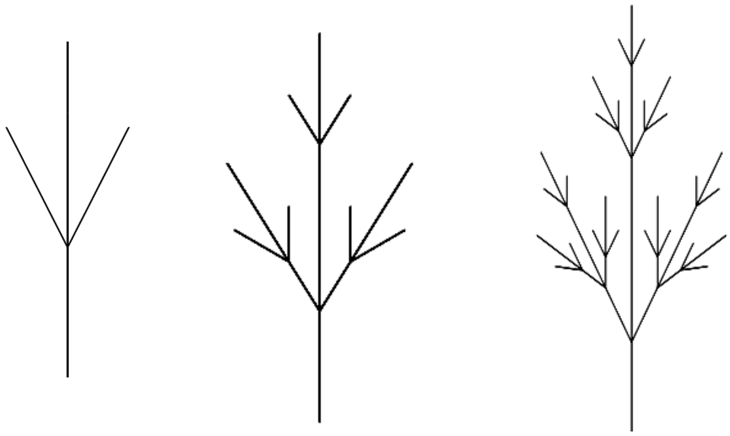

FIGURE 8. GEOMETRIC INTERPRETATION WITHOUT EXPERIMENT

After experiments activities using ICT Tool,
More than 75% of students realized that is possible create "S" form by using line and the angle and after some trial and error they could construct Lindenmayer system for the leave of marigolds. They used the strategies by change the angle small enough to have smooth curve for the stem leaf.
Here the several results of this task, the system and the geometric representations.

(a). Aksioma:
F-F-F-F-F-F-F-F-F-F-[---FFFFFA][F+F+F+F+F+F+F+F+FF-F-F-FA][++++++++++FFFFFA]
Rules: F=FF
A=[-----FFFFFFA][FFFFFFFFFFA][+++++FFFFFFA]
Angle = 7^0
The strategies they used: form a shape of "S" using small angle in axiom for the stem leaf and created the rules for the leaves.
The interpretation using "Inkscape" the produced this image:

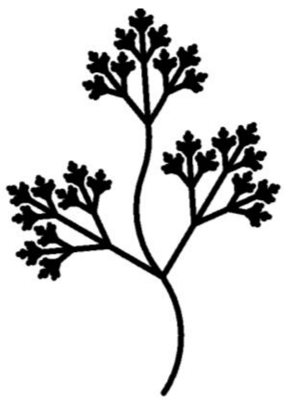

FIGURE 9. INTERPRETATION USING INKSCAPE

(b). Axiom :
F-F-F-F-F-F-F-F-F-F[F-F-F-F--F--A][F+F+F+F+F+F+F+F+FF--F--F-FA][++++F++F++F++F++FA]
Angle : 7°

Initial Angle : 31°
Rules : A=[-----FFFFFFA][FFFFFFFFFFFFA][+++++FFFFFFA]
F=FF
By using fractal grower, they produced this following image;

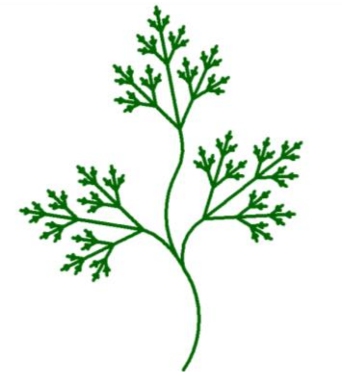

FIGURE 10. INTERPRETATION USING FRACTAL GROWER

TASK 4.
After the students made the constuction for “S” shape, they could create different shape more fluently than before, it is shown from their constructions for this task, when they chose the object freely that they could find in their neighbourhood and the ICT that they used.
Here, some of the works of students,
(a). “Samber gledhek” flower is created using “ Fractal Grower”.

FIGURE 11. SAMBER GLEDHEK FLOWER

Aksioma : ![G][+++F][---F]
Aturan : F=![G][++F][--F]
G=HG
Sudut : 13°

These are the fractal grower production for this system with n=1, 2 and 8 recursively

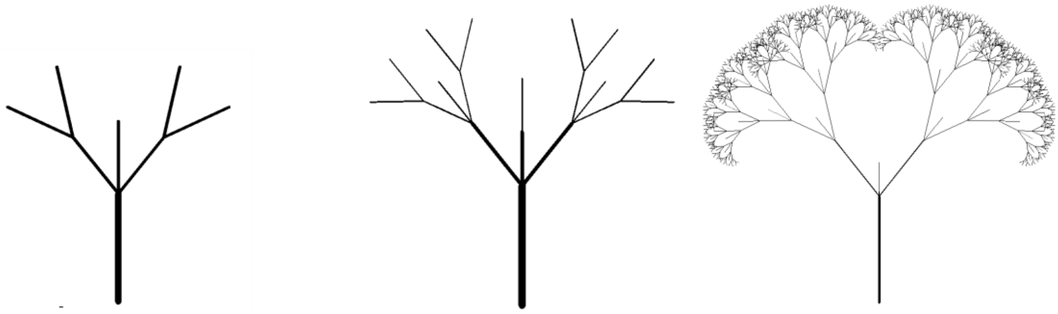

FIGURE 12. GEOMETRY OF SAMBER GLEDHEK FLOWER

(b). Palm tree created by fractal grower

FIGURE 13. PALM TREE

Axiom : !!!![-FFFA]FF[++FFFC]FF[--FFFB][+FFFA][--FFFA][+++FFFD]FFFD
Rules : A=AA[+FFFFF+FFF+F]F[-FFFFF-FFF-F]FA
B=B[+FFFFF+FFF+F]-FC[-FFFFF-FFF-F]FB
C=C[+FFFFF+FFF+F]+F[-FFFFF-FFF-F]FC
D=A[+FFFFF+FFF+F]-F[-FFFFF-FFF-F]FC--A
Angle : 20
The interpretaion of the system using fractal grower for n=1,2 and 4 recursively

FIGURE 14. GEOMETRY OF PALM TREE

(c). Radial tire of a car

FIGURE 15. FIGURE OF RADIAL TIRE

The Lindenmayer system of this tire is:
Axiom : +F+F+F+F+F+F+F+F+F+F+F+F+F
Rules : F=A[+A][- - - - -A][A++AA- -A++F]
Angle : 30
The interpretaion of the system using inkscape for n=1,2 and 4 recursively.

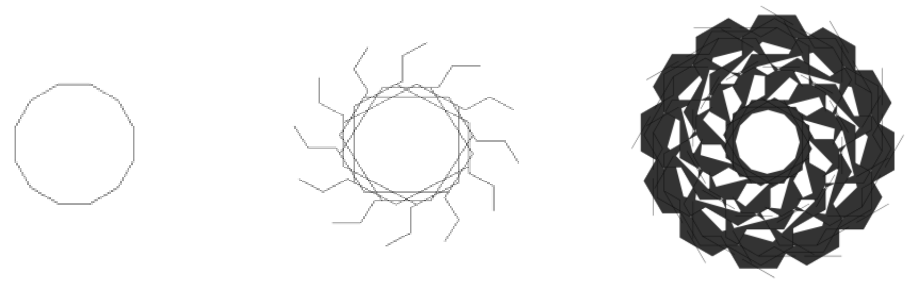

FIGURE 16. GEOMETRIC OF TIRE

III. CONCLUSIONS

From the analized data of the works of students before and after experiments activities, we have:

1. Using the experiments activities with ICT tool, the students realized that a shape “S” can be created using lines with the angle small enough so that the curve is smooth. In other words, the students made a relation between the shape and the angle.
2. The use of ICT tool and experiment activities, helped the students to make a guess about their system for an image and check it and change the system to make a better geometric representation of the system.
3. With using ICT tool, the student could create systems for variuos fractal objects that was difficult to realize without ICT tool.

Creative Problem Solving to Improve Students' Higher Order Thinking Skills in Mathematics Instructions

Ezi Apino[1], Heri Retnawati[2]
[1]Master Program of Mathematics Education, Yogyakarta State University
[2]Faculty of Mathematics and Natural Science, Yogyakarta State University
apinoezi@gmail.com

Abstract—The 21st century skills requires students not only have the conceptual knowledge, but also must have the skills to think and skill in the application of knowledge. High order thinking skills (HOTS) is one of the skills that students required to face the competition in the 21st century. One effort that can be done to improve students' HOTS namely through the implementation of creative problem solving (CPS) models in mathematics instruction. CPS can be implemented in mathematics instructions through the steps: (1) finding the objective of the problems (objective-finding); (2) analyzing facts or informations from the problems (fact-finding); (3) analyzing the important questions from the problem (problem-finding); (4) exploring ideas to solve the problem (idea-finding); (5) analyze the advantages and disadvantages of the ideas found (solution-finding); and (6) making the conclusion from the process of problem solving (acceptance-finding). CPS can improve students' HOTS because: (a) the product or outcomes of learning by using CPS can be used to evaluate high order thinking skills; (b) present a meaningful learning activities; (c) effectively used individually or groups; (d) empower students to construct the knowledge; (e) as a variation in learning activities that involve problem solving; (f) fostering the understanding that not all the problems have only one solution that is right; and (g) presentation of challenging problems (creative problem) can attract and motivate students to learn.

Keywords: *creative problem solving, higher order thinking skills, mathematics instructions*

I. INTRODUCTION

In this modern era everyone is required to have a variety of skills. Skills expected as mentioned in "21st century skills" covers creativity, reasoning, and problem solving. These skills can be seen as a higher order thinking skills (HOTS). In order to achieve these objectives various attempts have been made, one of which is through curriculum renewal. In Indonesia, curriculum which leads to increased student HOTS stated in "Curriculum 2013".

Implementation curriculum 2013 in Indonesia is not without obstacles. Retnawati [1] state that junior high school math teachers in Indonesia are still experiencing difficulties in implementing the curriculum in the classroom. The scientific method is becoming a pillar of the curriculum 2013 also can not be implemented effectively. This condition causes students' HOTS in Indonesia is still low.

Still lack students' HOTS in Indonesia apart caused by unreadiness of teachers, it can also be caused by use of the learning model that is less varied. Many literature states that HOTS can be enhanced through learning model that involves students in problem solving activities. It means, HOTS not only can be improved through the scientific method, but also need to try various learning models that oriented on improving students' HOTS.

One of learning models that can be used to improve students' HOTS is Creative Problem Solving (CPS). This article will explore what the CPS and implemented in mathematics instructions, as well as its implications for the improvement students' HOTS.

ISBN 978-602-74529-0-9

II. DISCUSSION

A. Higher Order Thinking Skills

Many experts define HOTS with different approaches and viewpoints. Resnick [2] argues that HOTS is hard to define, but easily recognizable by its characteristics. Further, Resnick [2] reveals some of the characteristics of HOTS, namely: (a) non-algorithmic, meaning that the action steps can not be fully determined at the beginning; (b) complex, meaning that steps can not be seen/predictable directly from a certain perspective; (c) generating a lot of solutions; (d) involve differences of opinion and interpretation; (e) involves the application of multiple criteria; (f) involves uncertainty; (g) requires self-regulated in the process of thinking; (h) involves the meaning impressive; and (i) requires effortfull.

Some of expert opinions relevant to definition HOTS as proposed by Thomas & Thorne [3] which states that the higher order thinking skills is thinking at level higher than just remembering facts or retell something audible to others. Furthermore Thomas & Thorne [3] states that the higher order thinking skills requires one to do something towards the facts, that is understand it, conclude, connect it with others facts and concepts, categorize, manipulate, putting the facts together in new ways, and apply them in finding a new solution of the problem. Lewis & Smith [4] states that higher order thinking skills occurs when a person obtains new information and stored it in memory and associates and or rearrange and extend information to achieve the goal or find a possible answer from confusion conditions. From opinions of experts it can be concluded that the HOTS require existence thinking process that more complex to face a situation or solve a problem.

If it is associated with thinking skills, HOTS can be seen as critical thinking and creative thinking [5, 6, 7,8], problem solving [6, 9], logical thinking, reflective thinking, and metacognitive [8], and decision-making [6]. Whereas if it is associated with cognitive processes in Bloom's taxonomy, the term HOTS often contrasted with the term LOTS (Lower Order Thinking Skills). Cognitive process analysis, synthesis, and evaluation are categorized as HOTS, while knowledge, understanding, and application are categorized as LOTS [10, 11]. Still relevant categorization HOTS and LOTS in Bloom's taxonomy, different opinions expressed by Thompson [12] which categorizes the analysis, synthesis, and evaluation as HOTS, knowledge and understanding as LOTS, while applications in the category HOTS or LOTS.

As if it is associated with Bloom's taxonomy revision proposed by Anderson & Krathwohl [13], the dimension of cognitive processes HOTS includes the process of analyze, evaluate, and create, while the dimensions of knowledge HOTS include conceptual knowledge, procedural knowledge, and metacognitive knowledge. (see. Table 1)

TABLE 1. HOTS IN BLOOM'S TAXONOMI REVISION

		The Cognitive Process Dimension					
		Remember	Understand	Apply	Analyze	Evaluate	Create
The Knowledge Dimension	Factual						
	Conceptual					Higher Order	
	Procedural					Thinking	
	Metacognitive					Skills	

Based on the theories that has been presented, the indicator HOTS in general can be developed through aspects of critical thinking and creative thinking, where these aspects are a major component in the process of higher order thinking skills, according the definition of HOTS noted previously.

Operationally, higher order thinking skills be detailed into indicators based on aspects of critical thinking and creative thinking. According to Ennis [14] critical thinking is "reasonable, reflective thinking that is focused on Deciding what to believe or do". Eggen & Kauchak [15] which states that critical thinking is the ability and the tendency of a person to make and do assessment toward conclusions based on evidence. Based on those two opinions, the critical thinking can be interpreted as an attempt to process and evaluate the information on a situation or issue based on strong evidence and logical. Critical thinking is characterized by ability to analyze and evaluate. The ability to analyze emphasis on the ability to specify a substance into its component parts and seeing the relationships between the parts. Anderson & Krathwhol [13] argues that the ability to analyze operationally characterized by their ability to differentiating, organizing, and attributing. Still according to Anderson and Krathwohl [13], to evaluate the ability can be defined as the ability to make an assessment (judgment) based on the criteria and certain standards. It is characterized by the ability of checking and critiquing.

In a lot of levels of thinking that has been compiled by experts, many of which put creative thinking as the highest levels of thinking. Krulik & Rudnick [7] states that "creative thinking is thinking that is original and reflective and that produces a complex product. ...includes synthesizing ideas, generating new ideas, and determining reviews their effectiveness. ... the ability to make-decisions ... ". Pressesisen [6] argues that creative thinking is using the basic thinking processes to develop or find a new idea or product, aesthetic, and constructive. Creative thinking is emphasized on how to use the information or materials that are known to generate original ideas and elaborating perspective. Based on those opinions, creative thinking is emphasized on how to process the existing information to generate new ideas or products. In other words, the ability to think creatively characterized by ability to create. More specifically Anderson & Krathwohl [13] argues that the ability to create can be characterized by ability to formulate/make hypotheses (generating), planning, and producing.

Based on the description that has been presented about the indicators of higher order thinking skills, the indicators that will be used to measure students' higher order thinking skills are summarized in table 2 below.

TABLE 2. DEVELOPMENT OF HOTS INDICATORS

HOTS Aspect	Indicator	Sub Indicator
Critical Thinking	Analyze	Differentiating
		Organizing
		Attributing
	Evaluate	Checking
		Critiquing
Creative Thinking	Create	Generating
		Planning
		Producing

B. Creative Problem Solving

Creative problem solving (CPS) is seen as one of the forms of variation in problem-based learning. One important and his experience.

Giangreco, Cloninger, Dennis, and Edelman [16] argues that the implications of the use of creative problem aspect that will be developed through this model is creativity of students in mathematics instructions. Bohan & Bohan [17] suggests that if we want students to be creative, we have to offer them something to be creative through knowledge. Thus through the application of creative problem solving, the students have the opportunity to be involved in the creative process in order to build knowledge based on prior knowledge solving in learning for students include:

1. Engage students in solving various problems and challenges in real life which a key characteristic of effective education.
2. Encourage students to believe that they can solve the problem, either independently or with the support of others in the class.
3. Offer opportunities for students (with either high or low academic ability) to assist in solving the challenges faced by them or their classmates and assign all students as a valuable contributor.
4. Offer opportunities for students to engage in the overall class according to their educational needs of each.
5. Offer the opportunity for students to learn and practice problem solving skills in a sustainable to address the relevant challenges.

6. Aspects of collaborative, non-judgmental, and action-oriented of creative problem solving encourage a sense of togetherness in addressing the challenges of concern to groups of students.
7. Encourage and strengthen many academic and affective skills (eg, observation, analysis, evaluation, took a point of view, build other ideas, synthesize ideas).

As for the implications of creative problem solving for teachers in learning [16], namely:

1. Encourage teachers to be open to the possibility that there is more than one correct answer.
2. Encourage teachers to continue to be learners and especially open themselves to learning from the students in their classes.
3. Provides a method to reduce the pressure in learning through group activities in problem solving.
4. Increase the capacity of teachers in teaching all students by identify the options that exist for teaching heterogeneous groups, adapting other options that already exist, and creating new options.
5. Encourage teachers to design attractive learning approaches and actively taking into account the contribution of the students.

Thus the creative problem solving in the learning process can trigger the implementation of active learning. Active here is not only focused that learning is solely centered on the student (student center), but teachers are also required to play a role in creating interesting circumstances of learning and in accordance with the needs of students, and to be able to develop creativity of students.

Associated with the implementation of creative problem solving in mathematics instructions, Bohan & Bohan [17] argues that this model has several characteristics, include: (1) help promote the kind of math class discussion becomes interesting and students excited to work; (2) presenting meaningful activities for students; (3) effectively used individually, cooperative groups, or as a classroom discussion; (4) empowers students to build knowledge in the field of mathematics; (5) produce products that can be used to evaluate higher order thinking skills.

Implementation of creative problem solving in mathematics instructions should be preceded by the presentation of open problems (open-ended) and non-routine [17]. More specifically Loewen [18] states that creative problem solving must use "creative problem". Creative problems is a problem that can be solved using many different strategies and the final answer is not singular [18]. According to Loewen term "creative problem" has differences with term "problems" in general (traditional problem). The difference can be observed through the following scheme:

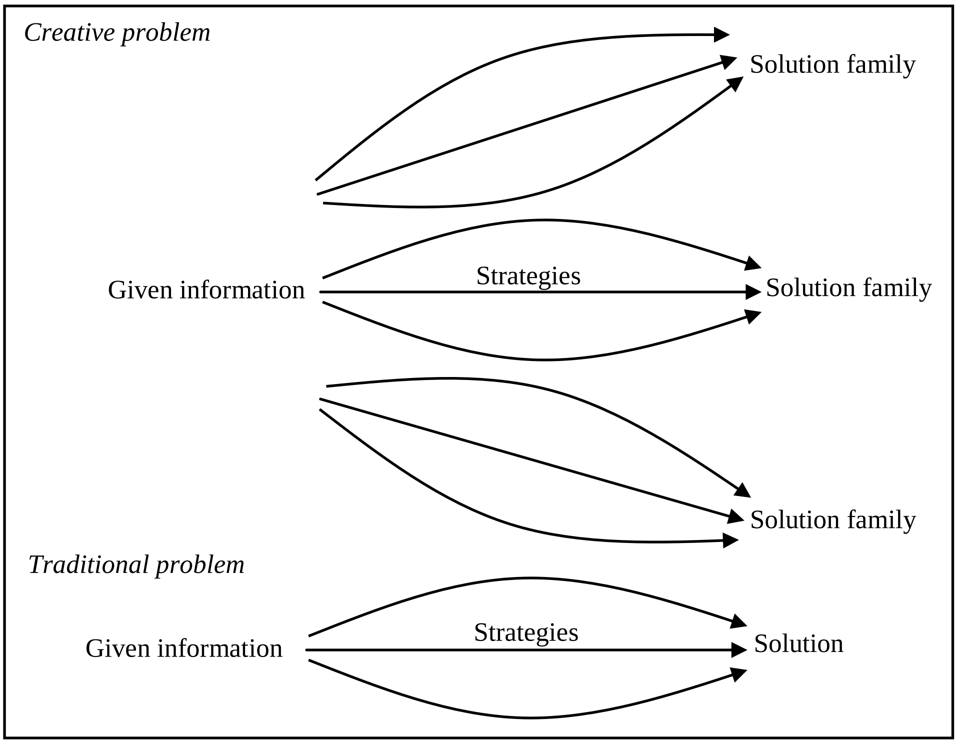

FIGURE 1. SCHEME OF CREATIVE AND TRADITIONAL PROBLEM

From the scheme shows that the traditional problems can be solved using different strategies, but the final answer is singular, whereas creative problem can also be solved using many strategies but produced no single solution.

According to Loewen [18], the advantages of the use of creative problems than traditional problem, namely:

1. Creative problem develop an understanding that not all the problems have only one correct solution.
2. Creative problem is more exciting, so it can add interest. With increasing interest in this, then it can increase the motivation in learning mathematics.
3. Creative problem can stimulate students to continue to consider ways to solve the problem.
4. Creative problem can come up with creative ideas for a problem solver, where this is one of the objectives to be achieved in the learning of mathematics.

In reality, not all mathematics problems can be presented through creative problem that has many solutions. In this case the creative problem solving can be facilitated with the filing of the problems that can be solved through a lot of ways (multiple ways). Pepkin [19] states that although creative problem solving is usually related to a problem that has many solutions, such as those found in management, math usually involve only one solution, but geometry and other material of math often pose a problem where there are a lot of ways to get the same solution. It can be concluded that one of the characteristics of the problems that could be used in the implementation of creative problem solving is a problem that can be solved in many ways (open process).

Based on the description above, it can be concluded that the creative problem solving can be implemented through the filing of a problem as the starting point of learning. the problems that may be filed in the creative problem solving that is open ended problems or creative problem, namely the problem that has many ways of settlement and many of the solutions, and the problems an open process, which is a problem that has many ways of settlement and a single solution.

Giangreco, et al [16] states syntax of creative problem solving that was adopted from Osborn (1993) and Parnes (1992) include:

1. Visionizing or Objective-Finding, which at this early stage, problem solver increase their awareness through imagining (imagined) potential challenges given.
2. Fact-Finding, where problem solver collect much information as possible about the challenges that selected by using all their senses and perceptions. By asking "who, what, where, when, why, and how". Problem solver completed this phase by identifying the facts that they believe are most relevant to the challenges.
3. Problem-Finding, where the purpose of this phase is to clarify the challenges or problems by redefining with new and different ways. By repeating the challenge as a question, "In what ways might I/we...?"; and by asking the question "Why?" or "What would really me/us to accomplish?" This process is repeated until a problem solver restate the problem in a way that the most reasonable and the most attractive for them.
4. Idea-Finding, this phase aim to generate as many ideas as possible that could potentially be used to solve the challenges or problems. At this phase problem solver try to make new connections between ideas by analogy, the manipulation of ideas, or create a new association from another ideas.
5. Solution-Finding, which at this phase problem solver will consider various criteria and was chosen to evaluate the advantages of the ideas put forward. Problem solver using criteria to assist in selecting the best solution.
6. Acceptance-Finding, where problem solver fix or repaire solution to be more easily applied. The goal is to transform ideas into action through the development and implementation of action plans.

C. Why CPS can improve students' HOTS?

Models of teaching can be used to improve students' higher order thinking skills is a model of teaching in which involves a problem solving activity. One model of teaching that involves problem solving activity that is creative problem solving. Noller [20] states that creative problem solving can be defined as a process, method, or system to approach a problem in an imaginative way and produce effective action. The same thing was stated by Treffinger [21] that creative problem solving is a framework in which individuals or groups can use it to: formulate the problem, have the opportunity or challenge; generate and analyze a lot of new ideas; and planning and implementing new solutions or action programs effectively. From both these opinions seem that creative problem solving is one alternative that can be used to solve the problem through a process of creative thinking.

CPS can be used to improve students' higher order thinking skills, as the opinion argued by Bohan & Bohan [17] that the product or the learning outcomes using CPS can be used to evaluate high-level thinking skills. There are several other reasons that CPS models used effectively to improve student HOTS:

1. In objectives finding phase, students are invited to analyze the objectives of the problem or challenge, it certainly can train students to think critically, where students are required not only understand the problem, but also need to know "for what" the problem is resolved.
2. In fact finding phase, students are asked to identify all the important informations contained on the problem. It can be used as a tool to train students to think critically, and can also be used as a reference that students begin to understand the problem.
3. In problem finding phase, students are asked to formulate the important questions of the problem or question relevant with the purpose of problem submission. In this case the students return required to be able to identify points that can be used as a guideline in preparing the questions, or at least the students were able to reformulate these questions in their own language. Similarly, the fact finding phase, this phase can also be used as a tool to improve students' critical thinking skills.
4. In idea finding phase, students are asked to explore ideas that can be used to solve the problem. The ideas came up expected purely arrival from result of students thinking. In this phase students can exchange opinions with friends to explore the possibility of ideas that can be used to solve the problem. Moreover, at this phase, students can also utilize a variety of learning resources that are relevant in order to find creative ideas. This process is expected to help students develop their creative thinking skills in solve the problems. This is based on presence student’s activity to create or formulate ideas that can be used to solve the problem.
5. In solutions finding, students are asked to apply the ideas that successfully formulated in ideas finding phase. In this phase, the students are expected to choose the best idea from the ideas that they found earlier. This requires students to be able to analyze the advantages and disadvantages of each idea that has been presented in the previous phase. Furthermore, students are expected to take a decision to determine which ideas will be used to solve the problem. These activities can certainly be used as a tool for students to train higher order thinking skills.
6. In acceptance finding phase, students are required to be able to make a conclusion of the process of solving the problem that they do. The formulation of this conclusion should be aligned with the formulation of the questions in problem finding phase. Thus, students are expected to make the appropriate conclusions.

Some other advantages of the implementation CPS in mathematics instructions in context of enhancement students’ HOTS:

1. Presenting meaningful learning activities, where meaningful learning can help students develop their creativity, so as to improve students’ HOTS.
2. Effectively used individually or in groups. Learning in group is needed students to exchange ideas and concepts. Such a process is needed to help improve students’ HOTS.
3. Empowering students to construct the knowledge. One of the factors that may affect the increase of students’ HOTS are familiarized students to construct the knowledge, not received the knowledge from teachers.

4. As variations in learning activities that involve problem solving. Problem solving as one of the strategies to improve students' HOTS, but it is very important to give the variation in problem solving activities, so that the students do not get bored.
5. Cultivate the understanding that not all the problems have only one correct solution. The presence of understanding of the students that there are mathematical problems that have more than one correct solution can train students to try various alternatives in finding solutions of the problems. This will further raise critical power and creativity of students.
6. Presentation of the challenging problem (creative problem) can attract and motivate students to learn. Challenging problems is the key factor in sharpening students' HOTS, which means that teachers have a role to facilitate students through submission the creative problems.

III. CONCLUSION

Models of teaching can be used to improve students' HOTS is a model of teaching in which involves a problem solving activity. One model of teaching that involves problem solving activity that is creative problem solving (CPS). CPS can be implemented in mathematics instruction through the steps: (1) finding the objective of the problems (objective-finding); (2) analyzing facts or informations that is critical of the problems (fact-finding); (3) analyzing the important questions of the problem (problem-finding); (4) exploring ideas to solve the problem (idea-finding); (5) analyze the advantages and disadvantages of the ideas found (solution-finding); and (6) implementing the best ideas to solve the problem (acceptance-finding). CPS can improve student's HOTS because: (a) the product/outcomes of learning by using CPS can be used to evaluate high order thinking skills; (b) present a meaningful learning activities; (c) effectively used individually or in groups; (d) empower students to construct the knowledge; (e) as a variation in learning activities that involve problem solving; (f) fostering the understanding that not all the problems have only one solution that is right; and (g) presentation of challenging problems (creative problem) can attract and motivate students to learn.

Effect Size Of Pakem Model Implementation In Mathematic Learning On Improving Student's Problem-Solving Mastery On Function Material At Junior High School

Fauzan Jafri[1]
[1]Department of Mathematics Education, Universitas Riau Kepulauan Batam
email: fauzan_jafri@yahoo.com

Abstract

This research is motivated by the level of junior high school students' mathematical problem solving was still low. Based on the preliminary study which conducted by one of the schools in Batam shows the average score for mathematics was 62 for 100 scale. The purpose of this study is to obtain and investigate the improvement of students' problem-solving mastery on relations and functions material as the effect of PAKEM model. The research method which used is pre-experiment and with one group pretest-posttest design. The subjects of this study were VIII grade students of one of the first junior school in Batam at odd semester 2015-2016 academic year, totally 32 students. Sample of this research were taken by random sampling technique. Students' problem solving mastery was measured by using problem-solving test, whereas the students' problem-solving mastery improvement between before and after the concept of effect size implementation was calculated to find the effect size of applying the PAKEM model. The result showed that the effect size of applying the PAKEM model on improving problem solving mastery is 3.3, it means, the PAKEM model implementation on improving problem-solving mastery on function has a strong influence. It can be concluded that the PAKEM model implementation can improve problem solving mastery.

Keywords: *effect size, the PAKEM model. problem-solving mastery*

I. INTRODUCTION

One of the goals of maths learning at school is to develop students' maths problem solving mastery. According to Devlin (Kurniawan, 2010), he explains that maths problem solving mastery is an important element in every learning process at any education levels and as one of the strength as the aim of maths learning at every junior high school level which gives a big change to the students to solve every problem related to the daily life,job, and other science matters.

The effort to develop maths problem solving mastery needs educators and researchers' attention seriously, because facts in the field, explains that maths problem solving mastery needs a serious attention and indicated as students' weakness point. The result of international survey report related to students' maths problem solving mastery in Indonesia,namely; Trends International Mathematics and Study (TIMSS) and the Programme for International Student Assessment (PISA) (Wardhani and Rumiati , 2011) points that Indonesian junior high school students' maths problem solving mastery in unroutine matters (mathematical problems) are still weak.

Learning process Improvements, especially in using appropriate models in learning process is one of solutions which researchers consider can improve students' maths problem solving mastery. One of suitable models to solve this problem is PAKEM. Model. PAKEM. Model will help students to maximize problem solving mastery, and be able to be to compete, active, effective, creative and intelligent in improving problem-solving mastery whithin himself. According to Daryanto (2013: 117), PAKEM Model is a learning model that allows students perform variuous activies (learning process)to develop the skills, attitudes, and understanding about various learning sources and devices including environment utilization so that learning more interesting, joyful, and effective. Besides it, PAKEM Model will invite students be able to maximize problem-solving mastery and to compete, role actively, effectively, creatively and intelligently on improving problem-solving mastery whithin himself.

The purpose of this study is to know the effect size of the implementation of PAKEM model in improving students' maths problem solving mastery in the functions material.

II. THEORIES

Rusman (2010 : 322) , PAKEM model is a learning model and becomes as a guideline in reaching assigned goals.PAKEM model characteristics:

1. Active

   It means, this learning model allows learners to interact actively with the environment , manipulate objects in it and observe the effect of those object manipulations.
2. Creative

   It means , learning to build learners' creativities in interacting with their environment, materials and other learners, particularly in facing the challenges or tasks that must be resolved in learning.
3. Effective

   It means, with active learning, creative and joyful can increase the learning effectiveness, which in turn can improve the quality of students' outcomes.
4. joyful

   It means, PAKEM model is designed to create a joyful learning atmosphere

The steps of PAKEM model learning according to Susanto (2013) which researcher applied in this study are as follows:

1. Review : teacher and students review previous material.
2. Development: the teacher constantly presents a new idea and expanding concept .
3. Controlled Exercise: teacher examines the misconceptions possibilities. It is recommended in group working.
4. Seat work: independent student or group in resolving issues / problem solving.
5. Individual/groups Reports: individual/group reports are reported for improvement needed.
6. Work display: the work is displayed which function as work appreciation at the classroom library / reading corner .
7. Giving homework for follow-up : homework should be corrected and valued .

III. RESEARCH METHOD

This study was a quasi-experimental study, design of the study was a one-group pretest - posttest. The population of this study was VIIIth grade student of one of junior high school in Batam, odd semester,2015-2016 academic year, while the sample was grade VIII3 students, they were 32 students. Sample technique was random sampling technique. The instrument used was the maths problem solving mastery test.

IV. RESULT AND DISCUSSION

In this stud, to determine the effect of the application of PAKEM model in learning used size effect equation which formulated by Cohen (1992)

$$\boldsymbol{d = \frac{\mu_{post} - \mu_{pre}}{\sigma_{pooled}}} \quad (\mathbf{1})$$

$$\boldsymbol{\sigma_{pooled} = \sqrt{\frac{\left(\sigma^2_{pre} + \sigma^2_{post}\right)}{2}}} \quad (\mathbf{2})$$

This equation was formulated to look at the effect size after treatment given, so that it needed to know the average value of class before (μ_pre) treatment given and the average value of the class after given treatment (μ_post) given. To determine the value of d, standard deviation was also needed before the treatment(σ_pre) given and standard deviation after treatment(σ_post) given. Categorizing the effect size toward concept understanding improvement by using the effect size formulation as follows .

Table 2. Effect size value criteria(d)

Value d	**Interpretation**
$0 \leq d \leq 0.20$	weak
$0.20 < d < 0.80$	medium
$d \geq 0.80$	Strong

source: (Rahmaniar & dkk: 2015)

After research conducted, to determine the effect size of the PAKEM model implemetation toward Mathematic Problem-Solving improvement, it was found result of the research which calculated using effect size formula as follows:

Table 3. Effect Size Of PAKEM Model Implementation On Improving Mathematic Problem-Solving Mastery recapitulation

N	μ_{pre}	μ_{post}	σ_{pre}	σ_{post}	Effect Size (d)
32	3.8	8.7	1.8	1	3.3

Source: (Rahmaniar dkk: 2015)

Based on the table, the researcher obtained the value of the effect size, 3.3, itindicates that the PAKEM model has a strong influence on improving students' mathematical problem solving mastery. The result was relevant to what Surantinah defines(in Ananda 2009: 6) that PAKEM Model is able to maximize problem solving mastery, and be able to compete, role actively, effectively , creatively and intelligently on improving problem-solving mastery within himsefl.

Figure 1 below, describes the effect size of the PAKEM Model implementation on improving mathematic problem solving mastery for each measured problem-solving mastery indicators, where the obtained effect size showed a strong influence too.

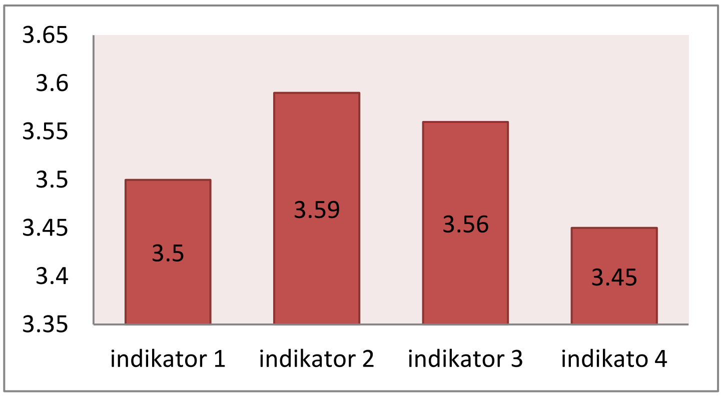

FIGURE 1. THE EFFECT SIZE FOR EACH INDICATORS

Information:
Indicator 1 : Understanding the problem
Indicator 2 : Choosing the suitable strategy to solve the problem
Indicator 3 : Resolving the problem correctly and systematically
Indicator 4 : Checking the accuracy of chosen strategy and the truth of problem solving gotten.

V. CONCLUSION :

PAKEM model has a strong influence on improving students' mathematic problem solving mastery in functions material. This is shown by the effect size achievement of 3.3 .

Improving Students' Logical Thinking Mathematic Skill Through Learning Cycle 5E and Discovery Learning

Gida Kadarisma
STKIP Siliwangi Bandung : Mathematic Education Dept.
gidakadarisma@yahoo.com

Abstract**—** This research is motivated by low of logical thingking mathematic skill junior high school students based on the results of the TIMSS 2011. This study aims to determine the increase logical thinking skill junior high school students who were taught by *learning cycle 5e* and *discovery learning*. This study is a quasi experimental and instrument of this research used the logical thinking skill tests include the skill to think mathematically proportional, probabilistic and correlational form of description as much as 4 questions that have been tested for validity and reliability. Population of this study is a junior high school students, the sample was taken two classes of ninth grade there is to be a experimental class 1 (using the learning cycle 5e) and experiment class 2 (using discovery learning). Before and after the experiment each class are given a pretest and posttest. Based on this research, it is known that there is no different improvement of students' logical thingking mathematic between students taught by using *Learning Cycle 5e* model and students taught by using discovery learning model.
Keywords: *Logical thinking Mathematic, Discovery Learning, Learning Cycle 5E.*

I. INTRODUCTION

Mathematics is the science which very useful for many people; therefore mathematics became one of the compulsory subjects that must be learnt by students at every level of formal education from elementary to high school. Mathematics and its learning are two things that can not be seen partially, due to the rapid of mathematics influenced by its learning in high school and college level. According to the Ministry of Education (2006), the aim of mathematics learning is to train how to think systematically, logically, critically, creatively and consistently [1].

The ability to think logically in learning mathematics is emphasized by every individual when need to take decisions, draw conclusions up to problem solving in everyday life sanely. The importance of the ability to think logically encountered in the vision and goals of mathematics teaching is to develop mastery of mathematical concepts, understanding and being able to apply mathematical concepts well in other subjects and in everyday life.

Apparently, based on the results of the study, mathematical logical thinking ability of students is still low. Lack of logical thinking ability of students can be seen from the results of the study by TIMSS in 2011. TIMSS is one of the international study to evaluate special education for the study of 14 year-old students at the level of junior high school (SMP), followed by Indonesia, where questions tested included measures of the students' ability to think logically. Rosmiati (2013) states that the average achievements of Indonesia on TIMSS 2011 is at a low level which is at rank of 386 and the mean of Indonesian participants' achievement has decreased from an average of the TIMSS 2007 which is the 397th rank [2].
Innovative and constructivism-based learning can be a solution to improve the ability to think logically for junior high school students. one of which is learning cycle 5E model. Learning Cycle 5E model aims to help developing students' thinking from concrete to abstract thinking. This model isnot only commonly used in the fields of science, but also is applied in mathematics. there are five phases in the Learning Cycle 5E model, namely engagement (attract attention-binding), exploration, explanation, elaboration (expansion), and evaluation.

Besides, learning model that can be used as a solution is discovery learning. Ruseffendi (2006: 329) argues that discovery is a method of teaching that is arranged normatively so that children can acquire the knowledge they do not know previously through their own effort and within their teacher's help[3]. As noted by Taba (Trisnadi, 2006: 21), the discovery method involves an inductive sequence. this sequence begins not with the explanation on a general principle but exposes students to some examples of principles where they can analyze, manipulate and experiment [4].

One of the advantages of learning through discovery learning is to lead the development of intellectual potential of students. By discovering relationships and regularities of the material being studied, the student becomes easier to understand the structure of the material being studied. So, students will more easily remember the concepts, facts, algorithms / procedures and principles in mathematics.

Based on the explanation above, the formulation of the problem in this paper is “Is there a significant difference in improvement on the logical thinking between students who use learning cycle 5e with those who use discovery learning?

II. THEORITICAL REVIEW

A. Mathematical Logical Thinking Ability

Logic can be defined as something that is in accordance with the logic, true by reasoning and reasonable. Logic in mathematics is often associated with the use of the rules of logic. Someone who played by the rules of logic can be said that the person is able to think logically. Saragih (2006) revealed that the logical thinking has differences with memorization [5]. Memorizing only refers to the achievement of a mere memory skills, whereas a more logical thinking refers to the notion of understanding, application ability, analytical skills, ability to synthesis, even the ability to develop skills evaluation (a process). Edward de Bono in Rosnawati (2011) divides the thinking patterns into a pattern of vertical and lateral thinking. Conventional patterns of thinking logically has been known and commonly used included into the mindset of vertical. This pattern of thinking is done step by step based on the facts to seek various alternative solutions to problems, and ultimately chose the most likely alternative according to normal logic[6].

In some discussions,the term of logical thinking (logical thinking) is often interchangeable with the term logical reasoning (logical reasoning) because both contain some similar activities. Indeed, the term logical thinking has a wider scope than logical reasoning . The term logical reasoning will contain activities to explain why and how a result is obtained or why and how to draw conclusions from available premises, or as a conclusion based on inference rule. While the term logical thinking load broader activities include completing mathematical problems in a rationally or reasonable (Sumarmo, 2011) [7].

Capie and Tobin (1980) in Sumarmo (1987) measure the ability of logical thinking based on the theories of mental development of Piaget to distinguish students stage of concrete operations and formal operations through the Test of Logical Thinking (Tolt) which consists of five components: Controlling variable , proportional reasoning, probabilistic reasoning, correlational reasoning, and combinatorial[8].

Logical thinking which the author want to examine adjusted with the level of junior high school students' thinking is the ability of probabilistic and correlational thinking, and the ability to think proportionately.

B. Learning Model Learning Cycle 5E

Learning Cycle model is a science-based contructivistic learning model. The model was developed by J. Myron Atkin, Robert Karplus and SCIs Group (Science Curriculum Improvement Study), at the University of California, Berkeley, USA since 1967. The theory of constructivism views that learning is a process of knowledge building bit by bit, which then the results are expanded through a limited context and it is not a sudden process. Knowledge is not a set of facts, concepts or rules that are ready to be retrieved or remembered. Man must construct knowledge and give meaning through real experience.

According to Soebagio, et al (2001: 50), Learning Cycle is a learning model that allows students to find their own concept or solidify concepts learned, prevent misconceptions, and provide opportunities for students to apply the concepts learned in new situations[9]. Learning Cycle model implementation in accordance with the view of constructivism learning where knowledge is built on self-learners.

The steps in each phase Learning Cycle 5E described by Lorsbach (2002) are as follows:

a. Engagement Phase. At this stage, the teacher prepare the students to learn, generate students' interest in math, and do a debriefing in exploring the students' prior knowledge. In the engagement phase, this interest and curiosity of the learners on topics which will be taught are tried to be resurrected. In this phase, learners are also invited to make predictions about the phenomenon to be studied and proven in the exploration stage.
b. Exploration Phase. At this stage, students work together in small groups to work on worksheets without direct instruction from the teacher. Students learn the concept itself from various sources and then discuss it with their friends n group..
c. Explanation phase. This stage is the stage of classical discussion. At this stage, the students explain the concept of the findings whitin their group with their own words, evidence and clarification of their explanations as well as comparing the arguments they have with the arguments of the other students.
d. Elaboration phase. At this stage, the students apply the concepts they got to solve the problems.
e. Evaluation Phase. Evaluation can be done through the provision of tests (quiz) or open-ended question at the end of the study to determine the extent of students' understanding of concepts learned, to evaluate the effectiveness of the previous phases and also evaluation of the knowledge, and to understand the concepts or competence of learners through problem solving in new contexts that sometimes encourage learners to investigate further[10].

Based on the stages in a cyclical learning method as described above, students are expected not only to hear the statements of teachers but it can also play an active role to explore and enrich their understanding of the concepts learned. Based on the above explanation, the learning cycle can be implemented in the areas of science and social.

Learning cycle should put forward because it is based on the learning theories of Piaget (Renner: 1988), constructivism learning theory. Piaget stated that learning is the development of cognitive aspects include: structure, content, and functionality[11].

C. Discovery learning

Discovery learning is a learning process in which a concept is not presented in the final form, but students are required to organize themselves in finding a way of learning concepts (Department of Education, 2013)[12]. Model Discovery learning is to understand the concept, meaning, and relationships, through an intuitive process to finally come to a conclusion. Discovery occurs when an individual is involved, especially in the use of mental processes to find some of the concepts and principles. Discovery is done through observation, classification, measurement, prediction, determination and Inferi. As a learning strategy, Discovery learning has the same principle as the inquiry and Problem Solving. There is no difference in principle on these three terms; Discovery learning is more emphasis on the discovery of concepts or principles that were previously unknown. The difference with the discovery learning is that the discovery problem that confronted the students is some sort of problem that is created by the teacher, while the problem in inquiry is not the result of the teacher's creation, so students have to put all of their effort, mind and skill to get the findings in the matter through the research process.

Problem Solving puts more emphasis on problem-solving ability. However, the principle of learning clearly visible in Discovery learning is that the material or learning material to be delivered are not delivered in final form, but students as learners are encouraged to identify what they want to know followed by finding the information them selves, then they organized and formed (constructively) what they know and they understand in a final form.

In the end, the objectives of the Discovery learning model proposed by Bruner is to let the teacher provides the opportunity for students to become a problem solver, a scientist, historian or mathematician. Through these activities, the students will master, implement, and find things that are beneficial to them. The most obvious characteristic of the Discovery as a model of teaching is that after the initial teaching levels (with the previous), teachers' guidance would be less involved compares with other teaching methods. It does not mean that teachers stop to give a guidance after the problems presented to students. The guidance given is not only reduced directly but students are given greater responsibility for their own learning.

The stages of discovery learning (Department of Education, 2013)

a. Stimulation (Giving Stimulation)

First of all, students are faced with something that causes confusion, then proceeded to not give a generalization, so that they have desire to investigate it by them selves. Besides, teachers can start teaching and learning activities by asking questions, suggestions reading books, and other learning activities that lead to the preparation of problem solving.

b. Problem Statement (Identification of Problems)

After stimulation, the next step is teachers allowed students to identify as much as possible the agenda of issues which relevant to learning materials, then one of them is selected and formulated in hypothetical form (temporary answer to the question problem)

c. Data Collection (Data Collection)

When the ongoing exploration happens, teachers also provide an opportunity for the students to gather as much information relevant to prove the correctness of the hypothesis. This stage serves to answer questions or to prove the truth of the hypothesis. Thus the students are given the opportunity to collect (collection) of various relevant information, read the literature, observing the objects, interviews with informants, do their own trials and so on.

d. Data Processing (Data Processing)

Data processing is an activity to process the data and information that has been obtained by the students through interviews, observation, and so forth, and then interpreted. All information results of readings, interviews, observation, and so on, are all processed, randomized, classified, tabulated, even it is calculated and interpreted in a certain way at a certain confidence level. Data processing is also called the coding / categorization that serves as the formation of concepts and generalizations. From generalizations, students will gain new knowledge about alternative answers / settlement that needs proof logically.

e.Verification (Proof)

At this stage, the students perform a careful examination to prove whether or not the hypothesis set forth earlier by finding alternatives, associated with the results of data processing Verification according to Bruner, aimed to make the learning process will go well and creative if the teacher gives students the chance to find a concept , theory, rules or understanding through examples that he encountered in his life. Based on the results of processing and interpretation or information, statements or hypotheses that have been formulated earlier was then checked, whether answered or not, whether proven or not.

f. Generalization (Interesting Conclusion)

generalisation / conclusion drawing phase is an interesting process that can be used as a general principle and application to all event or the same problem, taking into account the results of the verification[12].

III. RESEARCH METHOD

This study is a quasi-experimental research, with pretest-posttest control group design which used two classes as sample. The first class is the experimental class 1 that was taught using 5E learning cycle and the second group is the class that was taught using Discovery Learning and called as the experimental class 2. The population is one of the junior high school in Cimahi. Sample was selected 2 class from 9 class available. According Ruseffendi (2010) Design research is as follows [13]:

:

$O \quad X_1 \quad O$

- - - - - - - - - - - - - - - -

$O \quad X_2 \quad O$

Information :

O : pretest and posttest of mathematic logical thinking ability

X1 : Learning activity using learning Cycle 5E model

X2 : Learning activity using discovery learning model
------ : Sampling is not randomly taken

IV. DISCCUSION

Here are the finding of students' logical thihnking ability :

TABEL 1. Statistical description of Mathematic Logical Thinking Ability

Data	***Learning Cycle 5E***				***Discovery Learning***			
	Pretes	**Postes**	**Gain**	**N**	**Pretes**	**Postes**	**Gain**	**N**
$\bar{x}$	1.45	5.21	0.36	33	2.85	5.78	0.33	33
S	1.54	2.88	0.25		1.50	2.20	0.19	

From the data served in Table 1, it can be seen that the improvement of the mathematic logical thinking ability of the students who used learning cycle 5e is higher than those who used discovery learning (means of the gained score). Based on this finding, t-test is applied to examine the significant difference between the two means of score.

Tabel 2. T-test of Mathematic Logical Ability

Test	Sig	Finding	Interpretation
Gained mathematic logical thinking	0.588	Ho is accepted	There is no significant difference between the improvement of mathematic logical thinking ability of the students who used learning cycle 5e method and those who used discovery learning method.

From the finding obtained, there is no significant difference between those two methods. It means that both learning cycle 5e method and discovery method serve the same good effect on improving the students' logical thinking. It can be seen from the gained score of each method which comes to the average category.

Based on the data analysis above, it can be concluded that there is no significant difference on the students' mathematic logical thinking ability between the students who used learning cycle 5e model and discovery learning model. The two models are able to improve mathematic logical thinking ability of the junior high school students well.
